A New and Complete DICTIONARY OF Arts and Sciences;

Including the latest Improvement and Discovery

And the Present State of every branch of Human Knowledge.

BY G. GREGORY. D.D.

Domestic Chaplain to the Bishop of Landaff. Author of the Economy of Nature. &c. &c.

IN THREE VOLUMES.

Vol. 2.

PHILADELPHIA.

PUBLISHED BY ISAAC PEIRCE,

Nº. 316 Market Street,

1816.

A

DICTIONARY

OF

ARTS AND SCIENCES.

BY G. GREGORY, D. D.

DOCTOR IN PHILOSOPHY AND THE ARTS, AND HONORARY MEMBER OF THE IMPERIAL UNIVERSITY OF WILNA; MEMBER OF THE MANCHESTER AND NEWCASTLE LITERARY AND PHILOSOPHICAL SOCIETIES; HONORARY MEMBER OF THE BOARD OF AGRICULTURE; DOMESTIC CHAPLAIN TO THE LORD BISHOP OF LANDAFF; AUTHOR OF ESSAYS HISTORICAL AND MORAL, THE ECONOMY OF NATURE, &c. &c.

IN THREE VOLUMES.

VOL. II.

FIRST AMERICAN, FROM THE SECOND LONDON EDITION,

CONSIDERABLY IMPROVED AND AUGMENTED.

PHILADELPHIA:

PUBLISHED BY ISAAC PEIRCE, No. 316 MARKET STREET.

SOLD ALSO BY COALE AND MAXWELL, BALTIMORE, AND JAMES F. SHORES, PORTSMOUTH, N. H.

DENNIS HEARTT, PRINTER.

1816.

A

DICTIONARY

OF

ARTS AND SCIENCES.

ETHULIA, a genus of the class and order syngenesia polygamia æqualis. The receptacle is naked; down none. There are six species, chiefly annuals of the East Indies.

ETHUSA, fool's parsley. See ÆTHUSA.

ETNA. See VOLCANO.

ETYMOLOGY, that part of grammar which considers and explains the origin and derivation of words, in order to arrive at their first and primary signification, whence Quintilian calls it *originatio*.

The best treatise on the etymology of English words, and for the ascertaining of their force and usage, is unquestionably the Epea Pteroenta of Mr. Horne Tooke, already quoted in this work.

EVACUANTS. See MATERIA MEDICA.

EVANTES, in antiquity, the priestesses of Bacchus, thus called, because in celebrating the orgia, they ran about as if distracted, crying, *evan, evan, ohe' evan.*

EVAPORATION, in chemistry, the setting a liquor in a gentle heat or in the air, to discharge its superfluous humidity, reduce it to a proper consistence, or obtain its dry remainder.

Evaporation, though generally considered as the effect of the heat and motion of the air, may be produced by a different cause. Fluids lose more by evaporation in the severest frost than when the air is moderately warm. Thus, in the great frost of 1708, it was found that the greater the cold the more considerable the evaporation. Ice itself loses much by evaporation.

EVAPORATION, in natural philosophy, is the conversion of water into vapour, which in consequence of becoming lighter than the atmosphere, is raised considerably above the surface of the earth, and afterwards by a partial condensation forms clouds. It differs from exhalation, which is properly a dispersion of dry particles from a body.

We are indebted to the experiments of Saussure and Deluc for much of our knowledge of the qualities of vapour. It is an elastic invisible fluid like common air, but lighter; being to common air of the same elasticity, according to Saussure, as 10 to 14, or, according to Kirwan, as 10 to 12.

When water is heated to 212°, it boils, and is rapidly converted into steam; and the same change takes place in much lower temperatures; but in that case the evaporation is lower, and the elasticity of the steam is smaller. As a very considerable proportion of the earth's surface is covered with water, and as this water is constantly evaporating and mixing with the atmosphere in the state of vapour, a precise determination of the rate of evaporation must be of very great importance in meteorology. Accordingly, many experiments have been made to determine the point by different philosophers. No person has succeeded so completely as Mr. Dalton; but many curious particulars had been previously ascertained by the labours of Richman, Lambert, Wallerius, Leidenfrost, Watson, Saussure, Deluc, Kirwan, and others.

1. The evaporation is confined entirely to the surface of the water: hence it is in all cases proportional to the surface of the water exposed to the atmosphere. Much more vapour of course rises in maritime countries, or those interspersed with lakes, than in inland countries.

2. Much more vapour rises during hot weather than during cold: hence the quantity evaporated depends in some measure upon temperature. The precise law has been happily discovered by Mr. Dalton. This philosopher took a cylindrical vessel of tin, whose diameter was $3\frac{1}{4}$ inches, and its depth $2\frac{1}{2}$ inches, filled it with water, and kept it just boiling for some time. The loss of weight in the minute was 30 grains, when the experiment was made in a close room without any draught of air; 35 grains when the vessel was placed over fire in the usual fire-place, there being a moderate draught of air, and the room close; 40 with a brisker fire and a stronger draught; and when the draught was very strong, he supposes the evaporation might amount to 60 grains in the minute. At the temperature of 180°, the quantity evaporated was one half of what was lost at 212°.

At 164° it was $\frac{1}{3}$ of that at 212°.

	152	$\frac{1}{4}$
	144	$\frac{1}{5}$
	138	$\frac{1}{6}$

And in general the quantity evaporated from a given surface of water per minute at any temperature is to the quantity evaporated from the same surface at 212°, as the force of vapour at the first temperature is to the force of vapour at 212°. Hence, in order to discover the quantity which will be lost by evaporation from water of a given temperature, we have only to ascertain the force of vapour at that temperature. Hence we see that the presence of atmospheric air obstructs the evaporation of water; but this evaporation is overcome in proportion to the force of the vapour. Mr. Dalton ascribes this obstruction to the vis inertiæ of air.

3. The quantity of vapour which rises from water, even when the temperature is the same, varies according to circumstances. It is least of all in calm weather, greater when a breeze blows, and greatest of all with a strong wind. The following table, drawn up by Mr. Dalton, shows the quantity of vapour raised from a circular surface of six inches in diameter in atmospheric temperatures. The first column expresses the temperature; the second the corresponding force of vapour; the other three columns give the number of grains of water that would be evaporated from a surface of six inches in diameter in the respective temperatures, on the supposition of there being previously no aqueous vapour in the atmosphere. These columns present the extremes and the mean of evaporation likely to be noticed, or nearly such; for the first is calculated upon the supposition of 35 grains loss per minute from the vessel of $3\frac{1}{2}$ inches in diameter; the second 45, and the third 55 grains per minute.

Temperature.	Force of vapour in inches.	Evaporating force in grains		
212°	30	120	154	189
20	.129	.52	[illegible]	[illegible]

4. Such is the quantity of vapour which would rise in different circumstances, on the supposition that no vapour existed in the atmosphere. But this is a supposition which can never be admitted, as the atmosphere is in no case totally free from vapour. Now when we wish to ascertain the rate at which evaporation is going on, we have only to find the force of the vapour already in the atmosphere, and subtract it from the force of vapour at the given temperature: the remainder gives us the actual force of evaporation; from which, by the table, we readily find the rate of evaporation. Thus, suppose we wish to know the rate of evaporation at the temperature 59°. From the table we see that the force of vapour at 59° is 0.5, or $\frac{1}{60}$ its force at 212°. Suppose we find by trials that the force of the vapour already existing in the atmosphere is 0.25, or the half of $\frac{1}{60}$. To ascertain the rate of evaporation, we must subtract the 0.25 from 0.5; the remainder 0.25 gives us the force of evaporation required; which is precisely one half of what it would be if no vapour had previously existed in the atmosphere.

By the table we see that on that supposition a surface of six inches diameter would lose one grain by evaporation per minute, instead of two grains, which would have been converted into vapour if no vapour had previously existed in the atmosphere. If the force of the vapour in the atmosphere had amounted to 0.5, which is equal to the force of vapour at the temperature of 59°, in that case no vapour whatever would rise from the water; and if the force of the vapour already in the atmosphere exceeded 0.5, instead of evaporation, moisture would be deposited on the surface of the water.

These general observations, for all of which we are indebted to Mr. Dalton, account in a satisfactory manner for all the anomalies which had puzzled preceding philosophers; and include under them all the less general laws which they had discovered. We must consider the discoveries of Mr. Dalton as the most important additions made to the science of meteorology for these many years.

5. As the force of the vapour actually in the atmosphere is seldom equal to the force of vapour of the temperature of the atmosphere, evaporation, with a few exceptions, may be considered as constantly going on.

Various attempts have been made to ascertain the quantity evaporated in the course of a year; but the difficulty of the problem is so great, that we can expect only an approximation towards a solution. From the experiments of Dr. Dobson of Liverpool in the years 1772, 1773, 1774, and 1775, it appears that the mean annual evaporation from the surface of water amounted to 36.78 inches. The proportion for every month was the following:

	Inches.		Inches.
January -	1.50	July - -	5.11
February -	1.77	August - -	5.01
March -	2.64	September -	3.18
April - -	3.30	October -	2.51
May - -	4.34	November -	1.51
June - -	4.41	December -	1.49

Mr. Dalton found the evaporation from the surface of water in one of the driest and hotest days of summer rather more than 0.2 of an inch.

If we believe Mr. Williams, the evaporation from the surface of land covered with trees and other vegetables is one-third greater than from the surface of water; but this has not been confirmed by other philosophers. From his experiments it appears, that in Bradford in New England the evaporation, during 1772, amounted to 42.65 inches. But from the way that his experiments were conducted, the amount was probably too great.

From an experiment of Dr. Watson, made on the 2d of June 1779, after a month's drought, it appears, that the evaporation from a square inch of a grass plot amounted to 12 grains in an hour, or 8.8 grains in 24 hours, which is 0.061 of an inch. In another experiment, after there had been no rain for a week, the heat of the earth being 110°, the evaporation was found almost twice as great, or = 0.108 of an inch in the day. The mean of these two experiments is 0.084 inches, amounting for the whole of June to 2.62 inches. If we suppose this to bear the same proportion to the whole year that the evaporation in Dr. Dobson's experiments for June do to the annual evaporation, we shall obtain an annual evaporation, amounting to about 22 inches. This is much smaller than that obtained by Mr. Williams. But Dr. Watson's method was not susceptible of precision. He collected the vapour raised on the inside of a drinking-glass; but it was impossible that the glass could condense much more than one half of what did rise, or would have been raised in other circumstances. But then the experiments were made in the hottest part of the day, when much more vapour is raised than during any other part of it.

The most exact set of experiments on the evaporation from the earth was made by Mr. Dalton and Mr. Hoyle, during 1796, and the two succeeding years. The method which they adopted was this: Having got a cylindrical vessel of tinned iron, ten inches in diameter, and three feet deep, there were inserted into it two pipes turned downwards for the water to run off into bottles: the one pipe was near the bottom of the vessel, the other was an inch from the top. The vessel was filled up for a few inches with gravel and sand, and all the rest with good fresh soil. It was then put into a hole in the ground, and the space around filled up with earth, except on one side, for the convenience of putting bottles to the two pipes; then some water was poured on to sadden the earth, and as much of it as would was suffered to run through without notice, by which the earth might be considered as saturated with water. For some weeks the soil was kept above the level of the upper pipe, but laterly it was constantly a little below it, which precluded any water running off through it. For the first year the soil at top was bare; but for the two last years it was covered with grass the same as any green field. Things being thus circumstanced, a regular register was kept of the quantity of rain water that ran off from the surface of the earth through the upper pipe (whilst that took place), and also of the quantity of that which sunk down through the three feet of earth, and ran out through the lower pipe. A rain-guage of the same diameter was kept close by to find the quantity of rain for any corresponding time. The weight of the water which ran through the pipes being subtracted from the water in the rain-guage, the remainder was considered as the weight of the water evaporated from the earth in the vessel. The following table exhibits the mean annual result of these experiments.

	Water through the two pipes. 1796. Inch.	1797. Inch.	1798. Inch.	Mean. Inch.	Mean Rain. Inch.	Mean Evap. Inch.
January	1.897—	.680—	1.774+	1.450+	2.458	1 008
February	1.778—	.918—	1.122	1.273	1 801	.528
March	.431—	.070—	.335	.279	.902	.623
April	.220—	.295—	.180	.232	1.717	1.485
May	2.027—	2.443+	.010	1.493+	4.177	2 684
June	.171—	.726	——	.299	2.483	2.184
July	.153—	.025	——	059	4.15,	4.095
August	——	——	.504	168	3 554	3 386
September	——	.976	——	.325	3.279	2.954
October	——	.680	——	227	2.899	2.672
November	——	1.044	1.594	.879	2.934	2.055
December	.200	3.077	1.878+	1.718+	3.202	..484
	6.877—	10 934—	7.379	8.402	33 560	25 158
Rain	30.629—	38.791—	31.259			
Evap.	23.725—	27.857—	23.862			

From these experiments it appears that the quantity of vapour raised annually at Manchester is about 25 inches. If to this we add five inches for the dew with Mr. Dalton, it will make the annual evaporation 30 inches. Now, if we consider the situation of England, and the greater quantity of vapour raised from water, it will not surely be considered as too great an allowance if we estimate the mean annual evaporation over the whole surface of the globe at 35 inches. Now, 35 inches from every square inch on the superficies of the globe make 94,450 cubic miles, equal to the water annually evaporated over the whole globe.

Was this prodigious mass of water all to subsist in the atmosphere at once, it would increase its mass by about a twelfth, and raise the barometer nearly three inches. But this never happens; no day passes without rain in some part of the earth, so that part of the evaporated water is constantly precipitated again. Indeed it would be impossible for the whole of the evaporated water to subsist in the atmosphere at once, at least in the state of vapour.

EUCALYPTUS, a genus of the hexandria monogynia class and order. The calyx is superior, permanent, truncate before flowering, covered with an hemispherical deciduous lid. Corolla, none; capsule four-celled, opening at top, inclosing many seeds. There are two species, lofty trees of New Holland; called also the red-gum tree, from a gummy matter, in which one of them, the resinifera, abounds. A single tree will, on being tapped, afford more than 60 gallons of juice, which when dried becomes a powerfully astringent gum resin, resembling that known in the shops by the name of kino, and found eminently efficacious in dysenteries, &c. Water dissolves of it only one-sixth part, but it dissolves abundantly in spirit of wine, to which it gives a blood-red colour.

EUCLEA, a genus of the diœcia dodecandria class and order. In both male and female the calyx is four or five-toothed; the corolla four or five-parted; the male stamina 12 to 15. In the female, the germ is superior; the styles two; berry two-celled. There is one species, a branching tree of the Cape.

EUCOMIS, a genus of the class and order hexandria monogynia. The calyx is inferior, six-parted, permanent, spreading; filaments united at the base into a nectary growing to the corolla. There are four species, plants of the Cape.

EUDIOMETER, an instrument for ascertaining the purity of the atmospherical air, or the quantity of oxygenous gas contained in it, chiefly by means of its diminution on a mixture with nitrous acid, or some similar substance.

After the composition of the atmosphere was known to philosophers, it was taken for granted that the proportion of its oxygen varied in different times and in different places; and that upon this variation the purity or noxious qualities of air depended. Hence it became an object of the greatest importance to be in possession of a method of determining readily the quantity of oxygen in a given portion of air. Accordingly, various methods were proposed, all of them depending upon the property which bodies possess of absorbing the oxygen of the air without acting upon its azote. These bodies were mixed with a certain known quantity of atmospheric air, in graduated glass vessels inverted over water, and the proportion of oxygen was determined by the diminution of bulk. These instruments received the name of eudiometers, because they were considered as measures of the purity of air. The eudiometers proposed by different chemists may be reduced to five.

1. The first eudiometer was made in consequence of Dr. Priestley's discovery, that when nitrous gas is mixed with air over water, the bulk of the mixture diminishes rapidly, in consequence of the combination of the gas with the oxygen of the air, and the absorption of the nitric acid thus formed by the water. When nitrous gas is mixed with azotic gas, no diminution at all takes place. When it is mixed with oxygen gas in proper proportions, the absorption is complete. Hence it is evident, that in all cases of a mixture of these two gases, the diminution will be proportional to the quantity of the oxygen. Of course it will indicate the proportion of oxygen in air; and by mixing it with different portions of air, it will indicate the different quantities of oxygen which they contain, provided the component parts of air are susceptible of variation. Dr. Priestley's method was, to mix together equal bulks of air and nitrous gas in a low jar, and then to transfer the mixture into a narrow graduated glass tube about three feet long, in order to measure the diminution of bulk. He expressed this diminution by the number of hundredth parts remaining. Thus, suppose he had mixed together equal parts of nitrous gas and air, the sum total of this mixture was 200 (or 2.00): suppose the residuum when measured in the graduated tube to amount to 104 (or 1.04), and of course that 96 parts of the whole had disappeared, he denoted the purity of the air thus tried by 104. A more convenient instrument was invented by Dr. Falconer of Bath; and Fontana greatly improved this method of measuring the purity of air. A description of his eudiometer was published by Ingenhouz, in the first volume of his Experiments: it was still farther improved by Mr. Cavendish in 1783; and Humboldt has lately made a very laborious set of experiments in order to bring it to a state of complete accuracy. But after all the exertions of these philosophers, the method of analysing air by means of nitrous gas is liable to so many anomalies, that it cannot be depended on.

Priestley and Fontana have proved, that the way of mixing the two airs occasions a great difference in the result: the figure of the vessels is equally important, and so is the water over which the mixture is made. And even when all these things are the same, the impurity of the nitrous gas may occasion the most enormous differences in the results.

Humboldt has shown that the nitrous gas ought to be prepared by means of nitric acid of the density 1.170; when a much stronger or weaker acid is employed, the gas produced is always contaminated with a great proportion of azotic gas. He has pointed out the solution of sulphat of iron as proper to ascertain the purity of the nitrous gas employed, by absorbing the nitrous gas, and leaving the azotic gas or other foreign gases. He has shown that when nitrous gas of the same degree of purity is made to mix very slowly with air, the vessel being carefully agitated during the mixture, the results, provided the experiment is performed with address, corres-

pond with each other. And he has made it probable, that when equal quantities of air and nitrous gas, so pure as to contain only about 0.1 of azotic gas mixed with it, are agitated together slowly over water, the diminution divided by 3.55, gives the quantity of oxygen contained in the air examined. But notwithstanding the ingenuity of his experiments, the anomalies attending this method are still so great as not to render it susceptible of accuracy. For that reason it is unnecessary to give a particular description of the different eudiometers invented to ascertain the purity of air by means of nitrous gas. The result of the numerous experiments which have been made with nitrous gas is, that the proportion of oxygen in atmospheric air varies in different places and at different times. The minimum is about 0.22, the maximum about 0.30; consequently if this method of analysing air is to be depended on, we must consider that fluid not as a permanent chemical compound, but as a body subjected to all the variations to which accidental mixtures are liable.

2. The second kind of eudiometer was proposed by Volta. The substance employed by that philosopher to separate the oxygen from the air was hydrogen gas. His method was, to mix given proportions of the air to be examined and hydrogen gas in a graduated glass tube; to fire the mixture by an electric spark; and to judge of the purity of the air by the bulk of the residuum. But this method is not susceptible of even so great a degree of accuracy as the preceding, when the object is to ascertain the precise quantity of oxygen gas in a given bulk of air. For if too little hydrogen gas is mixed with the air, not only the whole of the oxygen will not be abstracted, but a portion of the azote will disappear in consequence of the formation of nitric acid. On the other hand, if too much hydrogen is added, part of it will remain after the firing of the mixture, and increase the bulk of the residuum. Volta's eudiometer, then, though it may have its uses, is scarcely susceptible of giving us the analysis of air.

3. For the third kind of eudiometer, we are indebted to Scheele. It is merely a graduated glass vessel, containing a given quantity of air exposed to newly prepared liquid alkaline or earthy sulphurets, or to a mixture of iron-filings and sulphur, formed into a paste with water. These substances absorb the whole of the oxygen of the air, which converts a portion of the sulphur into an acid. The oxygen contained in the air thus examined, is judged of by the diminution of bulk which the air has undergone. This method is not only exceedingly simple, but it requires very little address, and yet is susceptible of as great accuracy as any other whatever. The only objection to which it is liable is its slowness; for when the quantity of air operated on is considerable, several days elapse before the diminution has reached its maximum.

But this objection has been completely obviated by M. De Marti, who has brought Scheele's eudiometer to a state of perfection. He found that a mixture of iron-filings and sulphur does not answer well, because it emits a small quantity of hydrogen gas, evolved by the action of the sulphuric acid formed by the absorption of the oxygen of the air upon the iron; but the hydrogureted sulphurets, formed by boiling together sulphur and liquid potass or lime-water, answered the purpose perfectly. These substances, indeed, when newly prepared, have the property of absorbing a small portion of azotic gas; but they lose this property when saturated with that gas, which is easily effected by agitating them for a few minutes with a small portion of atmospheric air. His apparatus is merely a glass tube, ten inches long, and rather less than half an inch in diameter, open at one end, and hermetically sealed at the other. The close end is divided into 100 equal parts, having an interval of one line between each division. The use of this tube is to measure the portion of air to be employed in the experiment. The tube is filled with water; and by allowing the water to run out gradually while the tube is inverted, and the open end kept shut with the finger, the graduated part is exactly filled with air. These hundredth parts of air are introduced into a glass bottle filled with liquid sulphuret of lime previously saturated with azotic gas, and capable of holding from two to four times the bulk of the air introduced. The bottle is then to be corked with a ground glass stopper, and agitated for five minutes. After this the cork is to be withdrawn while the mouth of the phial is under water; and for the greater security, it may be corked and agitated again. After this, the air is to be again transferred to the graduated glass tube, in order to ascertain the diminution of its bulk.

Air, examined by this process, suffers precisely the same diminution in whatever circumstances the experiments are made: no variation is observed whether the wind is high or low, or from what quarter soever it blows; whether the air tried is moist or dry, hot or cold; whether the barometer is high or low. Neither the season of the year, nor the situation of the place, its vicinity to the sea, to marshes, or to mountains, makes any difference. M. De Marti found the diminution always between 0.21 and 0.23. Hence we may conclude that air is composed of

0.78 azotic gas.
0.22 oxygen gas.
————
1.00

Scheele indeed found, that the absorption amounted to 0.27; but that was because he neglected to saturate his sulphuret with azotic gas; for when the portion of azotic gas which must have been absorbed, and which has been indicated by De Marti, is subtracted, the portion of oxygen in air, as indicated by his experiments, is reduced very nearly to 0.22. The trifling variations perceptible in his experiments were no doubt owing to the quantities of the mixture of sulphur and iron, by which he abstracted the oxygen, not being exactly the same at different times; the consequence of which would be, an unequal absorption of azotic gas.

4. In the fourth kind of eudiometer, the abstraction of the oxygen of air is accomplished by means of phosphorus. This eudiometer was first proposed by Achard. It was considerably improved by Reboul, and by Seguin and Lavoisier; but Berthollet has lately brought it to a state of perfection, as it is equally simple with the eudiometer of De Marti, and scarcely inferior to it in precision.

Instead of the rapid combustion of phosphorus, this last philosopher has substituted its spontaneous combustion, which absorbs the oxygen of air completely; and

when the quantity of air operated on is small, the process is over in a short time. The whole apparatus consists in a narrow graduated tube of glass containing the air to be examined, into which is introduced a cylinder of phosphorus fixed upon a glass rod, while the tube stands inverted over water. The phosphorus should be so long as to traverse nearly the whole of the air. Immediately white vapours rise from the phosphorus and fill the tube. These continue till the whole of the oxygen combines with phosphorus. They consist of phosphorus acid, which falls by its weight to the bottom of the vessel, and is absorbed by the water. The residuum is merely the azotic gas of the air, holding a portion of phosphorous in solution. Berthollet has ascertained, that by this foreign body its bulk is increased one-fortieth part. Consequently, the bulk of the residuum, diminished by $\frac{1}{40}$, gives us the bulk of the azotic gas of the air examined; which bulk, subtracted from the original mass of air, gives us the proportion of oxygen gas contained in it.

All the different experiments which have been made by means of this eudiometer, agree precisely in their result, and indicate that the proportions of the ingredients of air are always the same, namely, about 0.22 parts of oxygen gas, and 0.78 of azotic gas. Berthollet found these proportions in Egypt and in France, and Dr. Thompson found them constantly in Edinburgh in all the different seasons of the year. Thus we see that the analysis of air by means of phosphorus, agrees precisely with its analysis by means of hydroguretted sulphurets.

5. The fifth eudiometer has been lately proposed by Mr. Davy. In it the substance used to absorb the oxygen from air is a solution of sulphat or muriat of iron in water, and impregnated with nitrous gas. A small graduated glass tube, filled with the air to be examined, is plunged into the nitrous solution, and moved a little backwards and forwards. The whole of the oxygen is absorbed in a few minutes. The state of greatest absorption ought to be marked, as the mixture afterwards emits a little gas which would alter the result. By means of this and the two preceding eudiometers, Mr. Davy examined the air at Bristol, and found it always to contain about 0.21 of oxygen. Air sent to Dr. Beddoes from the coast of Guinea gave exactly the same result. This eudiometer, then, corresponds exactly with the two last.

In all these different methods of analysing air, it is necessary to operate on air of a determinate density, and to take care that the residuum is neither more condensed nor dilated than the air was when first operated on. If these things are not attended to, no dependance whatever can be placed upon the result of the experiments, how carefully soever they may have been performed. Now there are three things which alter the volume of air and other elastic fluids: 1. A change in the height of the barometer. 2. An increase or diminution of their quantity; the vessel in which they are contained remaining the same, and standing in the same quantity of water or mercury. 3. A change in the temperature of the air.

EVERGREEN, in gardening, a species of perennials which continue their verdure, leaves, &c. all the year: such are hollies, phillyrias, laurustinuses, bays, pines, firs, and cedars of Lebanon. See GARDENING.

EVES-DROPPERS, are such as stand under walls or windows, by night or day, to hear news, and to carry them to others, to cause strife and contention among neighbours. These are evil members in the commonwealth, and therefore by stat. Westminster 1. c. 33, are to be punished; and this misdeameanor is presentable and punishable in the court leet.

EUGENIA, the yamboo, a genus of the monogynia order, in the icosandria class of plants, and in the natural method ranking under the 19th order, hesperideæ. The calyx is quadripartite, superior; the petals four; the fruit a monospermous quadrangular plum. There are 11 species, natives of the hot parts of Asia and America. They rise from 20 to 30 feet high; and bear plum-shaped fruit, inclosing one nut. They are too tender to live in this country, unless they are constantly kept in a stove.

EVICTION, in law, signifies a recovery of lands or tenements by law.

When lands, &c. are evicted before rent reserved upon a lease becomes due, the lessee is not liable to pay any rent. Likewise, if on an exchange of lands, either of the parties is evicted of the land given in exchange, the party evicted may in that case re-enter his own lands. And a widow being evicted of her thirds, shall be endowed in the other lands of the heir.

EVIDENCE, is the testimony adduced before a court or magistrate of competent jurisdistion, by which such court or magistrate are enabled to ascertain any fact which may be litigated between the parties.

This may be of two kinds, viz. written or verbal: the former by deeds, bonds, or other written documents; the latter by witnesses examined viva voce.

Evidence may be further divided into absolute and presumptive; the former is direct, in positive or obsolute affirmance or denial of any particular fact; the latter collateral, and from the conduct of the parties, affords an inference that such a particular fact did or did not occur.

The party making an affirmative allegation which is denied by his adversary, is in general required to prove it: unless indeed a man is charged with not doing an act, which by law he is required to do; for here a different rule must necessarily prevail. And the rule is, that the evidence must be applied to the particular fact in dispute; and therefore no evidence not relating to the issue, or in some manner connected with it, can be received; nor can the character of either party, unless put in issue by the very proceeding itself, be called in question; for the cause is to be decided on its own circumstances, and not to be prejudiced by any matter foreign to it.

It is an established principle, that the best evidence the nature of the case will admit shall be produced; for if it appears, that better evidence might have been brought forward, the very circumstance of its being withheld, furnishes a suspicion that it would have prejudiced the party in whose power it is, had he produced it. Thus if a written contract is in the custody of the party, no verbal testimony can be received of its contents.

The law never gives credit to the bare assertion of any one, however high his rank or pure his morals; but requires (except in particular cases with respect to quakers) the sanction of an oath, and the personal attendance of the party in court that he may be examined and cross-

examined by the different parties; and therefore in cases depending on parole or verbal evidence, the testimony of persons who are themselves conversant with the facts they relate, must be produced; the law paying no regard, except under special circumstances, to any hearsay evidence. Thus in some cases, the memorandum in writing made at the time, by a person since deceased, in the ordinary way of his business, and which is corroborated by other circumstances, will be admitted as evidence of the fact.

What a party himself has been heard to say, does not fall within the objection. As to hearsay evidence, any thing therefore, which the party admits, or which another asserts in his presence and he does not contradict, is received as evidence against him; but what is said by his wife, or any other member of his family, in his absence, will be rejected.

But a distinction must be made between admission, and an offer of compromise, after a dispute has arisen. An offer to pay a sum of money in order to get rid of an action, is not received in evidence of a debt, because such offers are made to stop litigation, without regard to the question whether any thing or what is due.

Admissions of particular articles before arbitration are also good evidence, for they are not made with a view to compromise, but the parties are contesting their rights as much as they could do on a trial.

In cases where positive and direct evidence is not to be looked for, the proof of circumstance and fact consistent with the claim of one party, and inconsistent with that of the other, is deemed sufficient to enable the jury, under the direction of the court of justice, to presume the particular fact, which is the subject of controversy; for the mind comparing the circumstances of the particular case, judges therefrom as to the probability of the story, and for want of better evidence, draws a conclusion from that before it.

Written evidence has been divided into two classes: the one that which is public, the other private; and this first has been subdivided into matters of record, and others of an inferior nature.

The memorials of the legislature, such as acts of parliament, and other proceedings of the two houses, where acting in a legislative character, and judgment of the king's superior courts of justice, are denominated records; and are so respected by the law, that no evidence whatever can be received in contradiction of them; but these are not permitted to be removed from place to place, to serve a private purpose; and are therefore proved by copies of them, which in the absence of the original, are the next best evidence.

Of persons incompetent to give evidence.—All persons who are examined as witnesses, must be fully possessed of their understanding; that is, such an understanding as enables them to retain in memory the events of which they have been witnesses, and give them a knowledge of right and wrong.

A conviction of treason or felony, and every species thereof, such as perjury, conspiracy, barratry, &c. prevents a man when convicted of them, from being examined in a court of justice. When a man is convicted of any of the offences before-mentioned, and judgment is entered up, he is for ever after incompetent to give evidence, unless the stigma is removed, which in case of a conviction of perjury, on the stat. of 5 Eliz. c. 9. can never be by any means short of a reversal of the judgment; for the statute has in this case, made his incompetency part of his punishment: but if a man is convicted of perjury, or any other offence, at the common law, and the king pardons him in particular, or grants a general pardon to all such convicts, this restores him to his credit, and the judgment no longer forms an objection to his testimony; but an actual pardon must be shown under the great seal, the warrant for it under the king's sign manual not being sufficient. To found this objection to the testimony of a witness, the party who intends to make it, should be prepared with a copy of the judgment regularly entered upon the verdict of conviction; for until such judgment is entered, the witness is not deprived of his legal privileges.

Persons may also be incompetent witnesses, by reason of their interest in the cause. The rule which has the most extensive operation in the exclusion of witnesses, and which has been found most difficult in its application, is that which prevents persons interested in the event of a suit, unless in a few excepted cases of evident necessity, from being witnesses in it. Of late years the courts have endeavoured, as far as possible consistent with authorities, to let the objection go to the credit rather than the competency of a witness; and the general rule now established is, that no objection can be made to a witness on this ground, unless he is distinctly interested, that is, unless he may be immediately benefited or injured by the event of the suit, or unless the verdict to be obtained by his evidence, or given against it, will be evidence for or against him in another action, in which he may afterwards be a party; any smaller degree of interest, as the possibility that he may be liable to an action in a certain event, or that, standing in a similar situation with the party by whom he is called, the decision in that cause, may by possibility influence the minds of a jury in his own, or the like; though it furnishes a strong argument against his credibility, does not destroy his competency.

On the question, how far persons who have been defrauded of securities, or injured by a perjury or other crime, can be witnesses in prosecuting for those offences, the event of which might possibly exonerate them from an obligation they are charged to have entered into, or restore to them money which they have been obliged to pay; the general principle now established is this: the question in a criminal prosecution or personal act, being the same with that in a civil cause in which the witnesses are interested, goes generally to the credit, unless the judgment in the prosecution where they are witnesses, can be given in evidence in this cause, wherein they are interested. But though this is the general rule, an exception to it seems to be established in the case of forgery; for many cases have been decided, that a person whose hand-writing has been forged to an instrument, whereby if good he would be charged with a sum of money, or one who has paid money in consequence of such forgery, cannot be a witness on the indictment. In cases where the party injured cannot by possibility derive any benefit from the verdict in the prosecution, as in indictments for assault, and the like personal injury, his com-

petence has never been doubted. It is a general rule that a party cannot be examined as a witness, for he is in the highest degree interested in the event of it; but where a man is not in point of fact interested, but only a nominal party, as where members of a charitable institution are defendants in their corporate character, there is no objection to an individual member being examined as a witness for the corporation; for in this case he is giving evidence for the public body only, and not for himself as an individual. Peake's N. P. Cas. 153. Bul. N. P. 293.

But instances sometimes occur, in which persons substantially interested, and even parties in a cause, are permitted to be examined from the necessity of the case, and absolute impossibility of procuring other evidence.

In an action on the statute of Winton, the party robbed is a witness: and on the same principle of necessity it has been holden, that persons who become interested in the common course of business, and who alone can have knowledge of the fact, may be called as witnesses to prove it: as in the case of a servant who has been paid money, or a porter who in the way of his business delivers out or receives parcels, though the evidence whereby he charges another with the money or goods, exonerates himself from his liability to account to his master for them; for if this interest was to conclude testimony, there never would be evidence of any such facts. Bul. N. P. 289.

As no one can be witness for himself, it follows of course husband and wife, whose interest the law has united, are incompetent to give evidence on behalf of each other, or of any person whose interest is the same; and the law, considering the policy of marriage, also prevents them giving evidence against each other: for it would be hard that a wife, who could not be a witness for her husband, should be a witness against him; such a rule would occasion implacable divisions and quarrels between them. In like manner, as the law respects the private peace of men, it considers the confidential communications made for the purpose of defence in a court of justice. By permitting a party to intrust his cause in the hands of a third person, it establishes a confidence and trust between the client and person so employed.

Barristers and attorneys, to whom facts are related professionally during a cause, or in contemplation of it, are neither obliged nor permitted to disclose the facts so divulged during the pendency of that cause, nor at any future time; and if a foreigner, in communication with his attorney, has recourse to an interpreter, he is equally bound to secrecy.

Where a man has, by putting his name to an instrument, given a sanction to it, he has been held by some judges to be precluded or stopped from giving any evidence in a court of justice which may invalidate it; as in the case of a party to a bill of exchange or promissory note, who has been said not to be an admissible witness to destroy it, on the grounds that it would enable two persons to combine together, and by holding out a false credit to the world, deceive and impose on mankind. On this principle it was held that an indorser could not be a witness to prove notes usurious, in an action or a bond founded on such notes, though the notes themselves had been delivered up, on the execution of the bond. At one time this seems to have been understood as a general principle applicable to all instruments; but in a case where an underwriter of a policy of insurance, was called to prove the instrument void as against another underwriter, and objected to on this ground, the court declared, that it extended only to negotiable instruments, and he was admitted to give evidence destructive of the policy.

When a witness is not liable to any legal objection, he is first examined by the counsel for the party on whose behalf he comes to give evidence, as to his knowledge of the fact he is to prove. This examination, in cases of any intricacy, is a duty of no small importance in the counsel; for as on the one hand, the law will not allow him to put what are called leading questions, viz. to form them in such a way as would instruct the witness in the answers he is to give; so on the other, he should be careful that he makes himself sufficiently understood by the witness, who may otherwise omit some material circumstance of the case.

The party examined must depose those facts only of which he has an immediate knowledge and recollection; he may refresh his memory with a copy taken by himself from a day-book; and if he can then speak positively as to his recollection, it is sufficient; but if he has no recollection further than finding the entry in his book, the book itself must be produced. Where the defendant had signed acknowledgments of having received money, in a day-book of the plaintiff, and the plaintiff's clerk afterwards read over the items to him, and he acknowledged them all right, it was held. that the witness might refresh his memory by referring to the books, although there was no stop to the items on which the recept was written, for this was only proving a verbal acknowledgment, and not a written receipt.

Lord Ellenborough, upon the authority of lord chief justice Tully, has recently laid down a very important doctrine, viz. that no witness shall be bound to answer any question which tends to degrade himself, or to show him to be infamous.

EULOGY, in church history, a name by which the Greeks call the panis benedictus, or bread over which a blessing is pronounced, and which is distributed to those who are unqualified to communicate. The name eulogiæ was anciently given to the consecrated pieces of bread, which the bishops and priests sent to each other, for the keeping up a friendly correspondence: those presents likewise which were made out of respect or obligation, were called eulogiæ. St. Paulinus, bishop of Nola, about the end of the sixth century, having sent five eulogiæ, at one time, to Romanian, says, "I send you five pieces of bread, the ammunition of the warfare of Jesus Christ, under whose standard we fight."

Eulogy means likewise an encomium on any person, on account of some virtue or good quality. See Elogy.

EUMENIDES, Furies, in antiquity.

EUNOMIANS, in church history, christians in the fourth century. They were a branch of Arians, and took their name from Eunomius, bishop of Cyzicus, who was instructed by Ætius in the points which were then controverted in the church, after having at first followed

the profession of arms. Eunomius so well answered the designs of his master, and declaimed so vehemently against the divinity of the Word, that the people had recourse to the authority of the prince, and had him banished; but the Arians obtained his recal, and elected him bishop of Cyzicus. The manners and doctrines of the Eunomians were the same with those of the Arians.

EVOCATION, in Roman antiquity, a solemn invitation preferred by way of prayer, to the gods and goddesses of a besieged town, to forsake it and come over to the Romans, who always took it for granted that their prayers were heard, provided they could make themselves masters of the place.

EVOLUTE, in the higher geometry, a curve which, by being gradually opened, describes another curve. Such is the curve B C F (plate LIV. Miscel. fig. 85); for if a thread F C M be wrapped about, or applied to, the said curve, and then unwound again, the point M thereof will describe another curve A M M, called by Mr. Huygens, a curve described from evolution. The part of the thread, M C, is called the radius of the evolute, or of the osculatory circle described on the centre C with the radius M C.

Hence, 1. when the point B falls in A, the radius of the evolute M C is equal to the arch B C, but if not, to A B and the arch B C. 2. The radius of the evolute C M is perpendicular to the curve A M. 3. Because the radius M C of the evolute continually touches it, it is evident from its generation, that it may be described through innumerable points, if the tangents in the parts of the evolute are produced until they become equal to their corresponding arches. 4. The evolute of the common parabola is a parabola of the second kind, whose parameter is $\frac{27}{16}$ of the common one. 5. The evolute of a cycloid is another cycloid equal and similar to it. 6. All the arches of evolute curves are rectifiable, if the radii of the evolute can be expressed geometrically. Those who desire a more particular account of these curves, may refer to sir Isaac Newton's and MacLaurin's Fluxions, also Rowe's, Simpson's, and Vince's Fluxions.

EVOLUTION. See ALGEBRA.

EVOLUTION, in the art of war, the motion made by a body of troops, when they are obliged to change their form and disposition, in order to preseve a post, or occupy another, to attack an enemy with more advantage, or to be in a condition of defending themselves the better. See TACTICS.

EVOLVULUS, a genus of the tetragynia order, in the pentandria class of plants; and in the natural method ranking under the 29th order, campanaceæ. The calyx is pentaphyllous; the corrolla quinquefid and verticillated; the capsule trilocular; the seeds solitary. There are seven species, herbaceous plants, chiefly annuals of the East and West Indies.

EUNONYMUS, the spindle-tree; a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 43d order, dumosæ. The corolla is pentapetalous; the capsule pentagonal, quinquelocular, quinquevalved, and coloured; the seeds hooded. There are eight species. Of these the most remarkable are; 1. the Europæus, has an upright woody stem ten or fifteen feet high, with oblong opposite leaves: from the sides of the branches proceed small bunches of greenish quadrifid flowers, succeeded by pentagonous capsules, disclosing their red seeds in a beautiful manner in autumn. 2. The Americanus, or evergreen spindle tree, has a shrubby stem, dividing into many opposite branches, rising six or eight feet high, with spear-shaped ever-green leaves growing opposite, and from the sides and ends of the branches. The flowers are quinquefid and whitish, and come out in small bunches, succeeded by roundish, rough, and protuberant capsules, which rarely perfect their seeds in this country. Both these species are hardy, and will succeed in any soil or situation. The berries of the first sort vomit and purge very violently, and are fatal to sheep. If powdered and sprinkled in the hair, they destroy lice. If the wood is cut when the plant is in blossom, it is tough and not easily broken; and in that state it is used by watchmakers for cleaning watches, and for making skewers and tooth-pickers. Cows, goats, and sheep, eat this plant; horses refuse it.

EUPAREA, a genus of the class and order pentandria monogynia. The calyx is five-leaved: corolla, five or twelve petalled: berry superior, one-celled: seeds many.

There is one species, an herbaceous plant of New Holland.

EUPATORIUM, hemp-agrimony; a genus of the polygamia æqualis order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; the pappus feathery; the calyx imbricated and oblong; the style semibifid and long. There are 49 species, many of them herbaceous flowery perennials, producing annual stalks from two to three or five feet high, terminated by clusters of compound flowers of a red, purple, or white colour. They are easily propagated by seeds, or parting the roots in autumn or spring. One species, viz. the cannabinum, or water hemp-agrimony, is a native of Britain. It is found wild by the sides of rivers and ditches, and has pale red blossoms. It has an acrid smell, and a very bitter taste, with a considerable share of pungency. The leaves are much recommended for strengthening the tone of the viscera, and as an aperient; and said to have excellent effects in the dropsy, jaundice, and scorbutic disorders. Boerhaave informs us, that this is the common medicine of the turf-diggers in Holland, against scurvies, foul ulcers, and swellings in the feet, to which they are subject. The root of this plant is said to operate as a strong cathartic: but it is hardly used in Britain, and has no place in our pharmacopœias.

EUPHEMISM, in rhetoric, a figure which expresses things in themselves disagreeable and shocking, in terms implying the contrary quality: thus, the Pontus, or Black Sea, having the epithet ἀξενος, *i. e.* inhospitable, given it, from the savage cruelty of those who inhabited the neighbouring countries, this name, by euphemism, was changed into that of Euxinus.

Thus Ovid, Trist. lib. iii. el. 13.

> Dum me terrarum pars pene novissima Ponti,
> Euxinus falso nomine dictus, habet.

And again, in Trist. lib. v. el. 10.

> Quem tenet Euxini mendax cognomine litus.

In which significations, nobody will deny its being a species of irony: but every euphemism is not irony, for we sometimes use improper and soft terms in the same sense with the proper and harsh.

EUPHONY, in grammar, an easiness, smoothness, and elegance in pronunciation. It is properly a figure, whereby we suppress a letter that is too harsh, and convert it into a smoother, contrary to the ordinary rules; of this there are abundance of examples in all languages.

EUPHORBIA, spurge, a genus of the trigynia order, in the dodecandria class of plants; and in the natural method ranking under the 38th order, tricoccæ. The corolla is tetrapetalous or pentapetalous, placed on the calyx; the calyx is monophyllous and ventricose; the capsule tricoccous. There are 98 species, six of which are natives of Great Britain. They are mostly shrubby and herbaceous succulents, frequently armed with thorns, having stalks from ten or twelve inches to as many feet in height, with quadripetalous flowers of a whitish or yellow colour. They are easily propagated by cuttings; but the foreign kinds must be always kept in pots in a stove. If kept dry, they may be preserved for several months out of the ground, and then planted, when they will as readily take root as though they had been fresh. The juice of all the species is so acrid, that it corrodes and ulcerates the body wherever it is applied; so that physicians have seldom ventured to prescribe it internally. Warts, or corns, anointed with the juice, presently disappear. A drop of it put into the hollow of an aching tooth, gives relief, like other corrosives, by destroying the nerve. Some people rub it behind the ears, that it may blister. One of the foreign species, named esula, is such a violent corrosive, that if applied to any part of the body, it produces a violent inflammation, which is soon succeeded by a swelling that degenerates into a gangrene, and proves mortal. There is a species at the Cape, which supplies the Hottentots with an ingredient for poisoning their arrows. Their method of making this pernicious mixture, is by first taking the juice extracted from the euphorbia, and a kind of caterpillar peculiar to another plant which has much the appearance of a species of rhus. They mix the animal and vegetable matter; and after drying it, they point their arrows with this composition, which is supposed to be the most effectual poison of the whole country. The euphorbia itself is also used for this purpose, by throwing the branches into fountains of water frequented by wild beasts, which after drinking the water thus poisoned, seldom get one thousand yards from the brink of the fountain before they fall down and expire. This plant grows from about fifteen to twenty feet in height, sending out many branches full of strong spines. The natives cut off as many of the branches as they think necessary for the destruction of the animals they intend to poison. They generally conduct the water a few yards from the spring into a pit made for the purpose; after which they put in the euphorbia, and cover the spring, so that the creatures have no choice. No animal escapes which drinks of such water, though the flesh is not injured by the poison. The euphorbias may be easily distinguished from the cactuses and other plants, which they resemble, by pricking them with a pin, when a milky juice will always exude from the puncture. See Plate LV. Nat. Hist. fig. 189.

EUPHORBIUM, in pharmacy, a gum resin brought us always in loose, smooth, and glossy gold-coloured drops of granules. See Pharmacy.

EUPHRASIA, eyebright (from a vulgar notion that it was good in disorders of the eyes); a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 40th order, personatæ. The calyx is quadrifid and cylindrical; the capsule bilocular, ovato-oblong; the shorter two antheræ, with the base of the one lobe, terminated by a small spine. There are nine species; two of which annuals, viz. the officinalis and odontites, are natives of Britain. The first of these, which has blue flowers, is a weak astringent, and was formerly much celebrated in disorders of the eyes; but the present practice has not only disregarded its internal, but also its external, use. This plant will not grow but when surrounded by others taller than itself. Cows, horses, goats, and sheep, eat it; swine refuse it.

EURYA, a genus of the class and order dodecandria monogynia. The calyx is five-leaved, calycled; corolla, five-petalled; stamina, three; capsule, five-celled. There is one species, a shrubby plant of Japan.

EURYANDRA, a genus of the polyandria trigynia class and order. The calyx is five-leaved: corolla, three-petalled; filaments much dilated at top, with two disjointed antheræ; follicles, three. There is one species, a climbing plant of New Caledonia.

EURYTHMY, in architecture, painting, and sculpture, is a certain majesty, elegance and easiness, appearing in the composition of divers members, or parts of a body, painting, or sculpture, and resulting from the fine proportion of it. Vitruvius ranks the eurythmia among the essential parts of architecture; he describes it as consisting in the beauty of the construction, or assemblages of the several parts of the work, which renders its aspect, or its whole appearance, grateful; *e. g.* when the height corresponds to the breadth, and the breadth to the length.

EUSEBIANS, a name given to a sect of Arians. on account of the favour and countenance which Eusebius, bishop of Cæsarea, showed and procured for them at their first rise.

EUSTATHIANS, the same with the catholics of Antioch, in the fourth century; so called from their refusing to acknowledge any other bishop beside St. Eustathius, who was deposed by the Arians.

EUSTYLE, in architecture, a sort of building in which the pillars are placed at the most convenient distance from one another, the intercolumniations being just two diameters and a quarter of the column, except those in the middle of the face, before, and behind, which are three diameters distant.

EUTYCHIANS, in church history, christians in the fifth century, who embraced the errors of the monk Eutyches, maintaining that there was only one nature in Jesus Christ. The divine nature, according to them, had so entirely swallowed up the human, that the latter could not be distinguished; insomuch, that Jesus Christ was merely God, and had nothing of humanity but the appearance.

EWRY, in the British customs, an officer in the king's household, who has the care of the table-linen, of laying the cloth, and serving up water, in silver ewers, after dinner.

EXACTION, in law, a wrong done by an officer, or a person in pretended authority, in taking a reward or fee that is not allowed by law. A person guilty of exaction may be fined and imprisoned. It is often confounded with extortion.

EXACUM, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 20th order, rotaceæ. The calyx is tetraphyllous; the corolla quadrifid, with the tube globular; the capsule two-furrowed, bilocular, polyspermous, and opening at the top. There are 10 species, allied to the gentians, chiefly annuals, of the East Indies and Cape.

EXÆRESIS, in surgery, the operation of extracting or taking away something that is hurtful to the human body.

EXAGGERATION, in rhetoric, a kind of hyperbole, wherein things are augmented or amplified, by saying more than the truth, either as to good or bad. There are two kinds of exaggeration; the one of things, the other of words. The first is produced, 1. By a multitude of definitions. 2. By a multitude of adjuncts. 3. By a detail of causes and effects. 4. By an enumeration of consequences. 5. By comparisons. And 6. By the contrast of epithets and rational inference.

Exaggeration by words is effected, 1. By using metaphors. 2. By hyperboles. 3. By synonymous terms. 4. By a collection of splendid and magnificent expressions. 5. By pariphrasis. 6. By repetition. And, lastly, by confirmation with an oath: as for example, "Parietes, medius fidius, gratias tibi agere gestiunt."

Exaggeration, in painting, a method by which the artist, in representing things, charges them too much, or makes them too strong, either in respect of the design or the colouring. It differs from caricaturing, as the latter perverts or gives a turn to the features of the face, &c. which they had not; whereas exaggeration only heightens or improves what they had.

EXAMINATION. Justices before whom any person shall be brought for manslaughter or for felony, or for suspicion thereof, before they commit such prisoner, shall take his examination, and information of those who bring him, of the fact and circumstances; and as much thereof as shall be material to prove the felony, shall be put in writing within two days after the examination; and the same shall certify in such manner as they should do if such prisoner had been bailed, upon such pain as in the act 1 and 2 P. and M. c. 13. is limited.

EXAMINERS, in chancery, two officers of that court, who examine, upon oath, witnesses produced in causes depending there, by either the complainant or defendant, where the witnesses live in London or near it. Sometimes parties themselves, by particular order, are examined. In the country, above twenty miles from London, on the parties joining in commission, witnesses are examined by commissioners, being usually counsellors or attorneys not concerned in the cause.

EXANTHEMA, among physicians, denotes any kind of efflorescence or eruption, as the measles, purple spots in the plague or malignant fevers, &c.

EXARCH, in antiquity, an officer sent by the emperors of the East into Italy, in quality of vicar, or rather præfect, to defend that part of Italy which was under their obedience, and particularly the city of Ravenna, against the Lombards. The exarch resided at Ravenna, which place, with Rome, was all that was left to the emperors of their Italian dominions. The first exarch was under Justin the Younger, in the year 567, after Belisarius and Narses had driven the barbarians out of Italy. The last was Eutychius, defeated by Adolphus, king of the Lombards, in 752. But Pepin, king of France, deprived him of the exarchate, and made a gift of it to the pope, ordering his chaplain to lay the keys of all the towns on the altar of St. Peter and Paul at Rome.

Exarch also denotes an officer still subsisting in the Greek church, being a kind of visitor, or one deputed by the patriarch into provinces, to see whether the bishops do their duty, and whether the rest of the clergy observe the canons of the church.

There is another officer also of this name under the patriarchs of the Greek church, who has the care and inspection of the patriarchal monasteries, or such as depend immediately on the patriarch.

EXAUCTORATION, *exauctoratio*, in Roman antiquity, corresponded, in some measure, to our keeping soldiers or sailors in half-pay; but differed in this, that the exauctorati milites were deprived of their pay and arms, without being absolutely discharged. Sometimes it signifies a full but ignominious discharge.

EXCALCEATION, among the Hebrews, was a particular law, whereby a widow, whom her husband's brother refused to marry, had a right to summon him to a court of justice, and, upon his refusal, might excalceate him, that is, pull off one of his shoes, and spit in his face; both of them actions of great ignominy.

EXCELLENCY, a title anciently given to kings and emperors, but now to ambassadors and other persons, who are not qualified for that of "highness," and yet are to be elevated above the other inferior dignities.

In England and France the title is now peculiar to ambassadors, but very common in Germany and Italy. Those it was first appropriated to were the princes of the blood of the several royal houses; but they quitted it for that of highness, upon several great lords assuming excellency. The ambassadors have only borne it since the year 1593, when the pope complimented the duke de Nevers, ambassador from Henry IV. of France, with the title of excellency; and though it was on account of his birth, and not of his character, yet the ambassadors of all nations have ever since claimed the same appellation.

The ambassadors of Venice have only had the title of excellency since the year 1636, when the emperor and king of Spain consented to allow it to them. The court of Rome never allows that title to any ambassador who is a churchman, as judging it a secular title.

The ambassadors of France at Rome anciently gave the title of excellency to all the relations of the pope then reigning, and to several other noblemen; but now they are more reserved in that respect, though they still treat all the Roman princes with excellency: on the other hand, the court of Rome bestowed the same title on the chancellor, ministers, and secretaries of state,

and presidents of the sovereign courts of France, the presidents of the councils in Spain, and the chancellor of Poland, if they were not ecclesiastics.

EXCENTRIC, in geometry, a term applied to circles and spheres which have not the same centre, and consequently are not parallel; in opposition to concentric, where they are parallel, having one common centre.

EXCENTRIC, or *excentric circle*, in astronomy, is the circle described from the centre of the orbit of a planet, with half the greatest axis as a radius; or it is the circle that circumscribes the elliptic orbit of the planet, as the circle AQB. See Plate LIV. Miscel. fig. 86.

EXCENTRIC *anomaly*, or *anomaly of the centre*, is an arc AQ of the excentric circle, intercepted between the aphelion A, and the right line QH, drawn through the centre P of the planet perpendicular to the line of the apses AB.

EXCENTRIC *place of a planet*, is the point of the orbit where the circle of inclination coming from the place of a planet in its orbit, falls thereon with right angles.

EXCENTRICITY, in astronomy, is the distance CS between the sun S and the centre C of a planet's orbit; or the distance of the centre from the focus of the elliptic orbit, called also the simple or single excentricity. Fig. 86.

When the greatest equation of the centre is given, the excentricity of the earth's orbit may be found by the following proportion, viz.

As the diameter of a circle in degrees,
Is to the diameter in equal parts;
So the greatest equat. of the centre in degrees,
To the excentricity in equal parts. Thus,

Greatest equat. of the cent. $1^\circ\ 55'\ 33'' = 1^\circ.9258333$ &c.

The diameter of a circle being 1, its circumference is 3.1415926.

Then $3.1415926 : 1 :: 360^\circ : 114^\circ.5915609$ diameter in degrees.

And $114.5915609 : 1 :: 1.9258333 : 0.016806$, the excentricity.

Hence, adding this to 1, and subtracting it from 1,
Give $1{\cdot}016806 =$ AS the aphelion distance,
And $0{\cdot}983194 =$ BS the perihelion distance.

See Robertson's Elements of Navigation, book 5, pa. 286.

Otherwise, thus: Since it is found that the sun's greatest apparent semidiameter, is to his least, as $32'\ 43''$ to $31'\ 38''$, or as $1963''$ to $1898''$; the sun's greatest distance from the earth will be to his least, or AS to SB, 1963 to 1898; of which,

The half-dif. is $32\frac{1}{2} =$ CS,
And half-sum $1930\frac{1}{2} =$ CB; wherefore,
as $1930\frac{1}{2} : 32\frac{1}{2} :: 1 : .016835'' =$ CS the excentricity, to the mean distance or semi-axis 1; which is nearly the same as before.

The excentricities of the orbits of the several planets, in parts of their own mean distances 1000, and also in English miles, are as below, viz. the excentricity of the orbit of

		Parts.	Miles.
Mercury			7,730,000
Venus	-	7	482,000
Earth	-	17	1,618,000
Mars	-	93	13,486,000
Jupiter	-	48	23,760,000
Saturn	-	55	49,940,000
Herschel	-	$47\frac{1}{2}$	86,000,000
Piazzi	-	0,0364	

Double EXCENTRICITY, is the distance between the two foci of the elliptic orbit, and is equal to double the single excentricity above given.

To find the excentricity of the earth's orbit, and the place of the apsides.—Take an observation of Mars when he is in opposition with the Sun, and then if Mars be in M. (Plate LIV. Miscel. fig. 87.) the Sun in S, and the Earth in T, they will be all in the same right line M T S. When Mars, after 687 days, returns again to the same point M, and the Earth, not reaching the same till after $730\frac{1}{2}$ days, in which time she completes two revolutions in her orbit, is found in the point A, observe the place of the Sun seen from the Earth by the right line A S, and the place of Mars seen by the right line A M. We have, therefore, by means of the Sun's place in E, at the time of the second observation, and his place in F, at the time of the first observation, the angle E S F given, to which the angle M S A is equal. And by knowing the place of the Sun and Mars in the 2d observation, we have the distance of Mars from the Sun, or the angle M A S. In the same manner may be found the angle M S B, and B S, the distance of the Earth from the Sun in decimal parts of M S, when Mars returns a second time to M, and likewise the angle M S C, and the right line S C, when Mars returns a third time to M. Wherefore since the focus of the earth's orbit is in S, and A, B, and C are points in that orbit, the line of the apsides will be determined, the orbit will be described, and consequently the excentricity will be known. The excentricity of all the primary planets, and the position of the line of apsides, may be found in the same manner, if three heliocentric places of the planet, together with its true distance from the Sun, are known. But it must be observed, that we suppose that the planet, in the same point of its orbit, has the same distance from the Sun, which we may easily suppose on account of the slowness of the motion of the aphelia.

The excentricity of the moon's orbit is about 3, 3 of the semi-diameter of the Earth, and now and then it grows greater and now and then it diminishes. It is greatest when the line of the apsides is coincident with the syzygia, or is in the line which joins the centres of the Sun and Earth. And the excentricity is least when the line of the apsides cuts the other at right angles. The difference between the greatest and least excentricity is so considerable, that it exceeds the half of the least excentricity.

EXCEPTION in law, is a stop or stay to any action. In law proceedings, it is a denial of a matter alleged in bar to an action; and in chancery, it is what is alleged against the sufficiency of an answer.

EXCEPTION TO EVIDENCE. At common law, a writ of error lay for an error in law, apparent on the record, or for an error in fact, where either party died before judgment; yet it lay not for an error in law not appearing on the record. 2 Inst. 426.

By the stat. of Westminster 2, when one impleaded before any of the justices, alleges an exception, praying they will allow it; and if they will not, if he that alleges the exception writes the same, and requires the justices will put thereto their seals; the justices shall so do: and if upon complaint made of the justices, the king causes the record to come before him, and the exception is not found in the roll, and the plaintiff shows the written exception, with the seal of the justices thereto put, the justice shall be commanded to appear at a certain day, either to confess or deny his seal, and if he cannot deny his seal, they shall proceed to judgment according to the exception, as it ought to be allowed or disallowed.

The statute extends to the plaintiff as well as the defendant, also to him who comes in loco tenements, as one that prays to be received, or the vouchee; and in all actions, whether real, personal, or mixt. 2 Inst. 427.

Exception *in deeds and writings*, the exception in a clause whereby the donor, feoffer, grantor, or other person contracting, excepts or takes a particular thing out of a general thing granted or conveyed. The thing excepted is exempted, and does not pass by the grant, neither is it parcel of the thing granted; as if a manor be granted, excepting one acre, hereby in judgment of law, that acre is severed from the manor. 1 Wood's Convey. 241. Exception must be of such a thing as he who makes it may have, and does belong to him. It must not be the whole thing granted, but part thereof only. The thing excepted, must be part of the thing granted before, and not of some other thing. The thing excepted, must be such a thing as may be severed from the thing granted, and not inseparable incidents. It must be of a particular thing out of a general, or of an entire thing, and not of a particular out of a particular, or the whole thing itself granted. An exception must be conformable to the grant, and not repugnant thereto; and the thing excepted must be certainly described and set down.

EXCESS, in arithmetic and geometry, is the difference between any two unequal numbers or quantities, or that which is left after the lesser is taken from or out of the greater.

EXCHANGE, in law, is a mutual grant of equal interests, the one in consideration of the other. 2 Black. 323.

An exchange may be made of things that lie either in grant or in livery. But no livery of seisin, even in exchanges of freehold, is necessary to perfect the conveyance: for each party stands in the place of the other, and occupies his right, and each of them has already had corporal possession of his own land. But entry must be made on both sides; for if either party die before the entry, exchange is void, for want of sufficient notoriety. Id.

In exchange, the estates of both parties should be equal; that is, if the one has a fee simple in the one land, the other should have like estate in the other land: and if the one has fee-tail in the one land, the other ought to have the like estate in the other land: and so of other estates. But it is not material in the exchange, that the lands be of equal value, but only that they be equal in kind and manner of the estate given and taken. 1 Inst. 51.

Exchanges, are carried on by merchants and bankers all over Europe, and are transacted on the Royal Exchange of London, the Royal Exchange of Dublin, the Exchange of Amsterdam, and those of the principal cities of the continent. The mode of exchanging between one kingdom or nation and another, is, the one gives the certain price, and the other the uncertain price of exchange to each other: *i. e.* England gives the certain price, viz. one pound sterling, to France, for an uncertain number of livres to be paid or received there, and gives the same to Hamburgh, Holland, and the Netherlands, for an uncertain number of schillings and pence Flemish, or of guilders and stivers; and she gives the uncertain price, viz. an uncertain number of pence and parts of pence, to other nations: as for example, she gives from 60*d.* to 70*d.* (more or less) to Lisdon or Oporto for one of their milreis (or 1000 reis); from 30*d.* to 40*d.* to Madrid, Cadiz, &c. for their piastre or dollar; from 35*d.* to 55*d.* to Genoa and Leghorn for a pezzo, or dollar of 5 livres banco at Genoa, and 6 livres at Leghorn; from 25*d.* to 45*d.* to Naples for a ducat of 10 carlins or 100 grains; from 36*d.* to 56*d.* to Venice for a ducato banco of 24 grossi; from 30*d.* to 40*d.* to Petersburgh for a rouble of 100 copecks; and to Dublin and all parts of Ireland 100*l.* sterling for an uncertain number of pounds, shillings, and pence Irish, to be paid or received there, viz. from 105*l.* up to 115*l.* Irish, as exchange may be.

The par of exchange (or par pro pari) is the intrinsic value of the different species of money on the continent, equalized to those of England, and vice versa; as for instance, the par of exchange between England and Ireland is $8\frac{1}{3}$ per cent. or, in other words, 108*l.* 6*s.* 8*d.* Irish, are equal to 100*l.* English; the English shilling being current in that country for 13*d.* consequently the pound sterling is 1*l.* 1*s.* 8*d.* therefore when the exchange from London on Dublin is 12*l.* per cent. there is a profit or saving of 3*l.* 13*s.* 4*d.* per cent. on every 100*l.* sterling remitted to Ireland.

The course of exchange is always fluctuating, sometimes under, and sometimes over the par of exchange, and is chiefly governed by the balance of trade being for or against the negotiating parties; so that when the exchange is above par, the balance of trade is certainly against them, and when it is under par, it is consequently in their favour. If London ships to Hamburgh merchandize to the amount of 500,000*l.* and at the same time Hamburgh ships to London goods or merchandize to only the amount of 300,000*l.* Hamburgh can only discharge to the amount of 300,000*l.* by bills of exchange, and for the remaining balance of 200,000*l.* she must procure bills of exchange at the lowest possible premium elsewhere, in order to liquidate the debt due to London, (as it is not to be supposed that Hamburgh, being indebted to London, can furnish bills on equally good terms with another city not indebted to London): thus Hamburgh by paying a premium (of suppose 1 per cent.) for bills of exchange, would have to pay 202,000*l.* in order to liquidate the aforesaid balance of 200,000*l.* thereby losing 2000*l.* on the transaction.

Thus it is that the balance of trade effects the fluctuation of exchanges. The principal exchanges of Europe are governed by those of London, Amsterdam, and Venice, and the exchanges from foreign countries are to be only

had by advices from the merchants and bankers residing abroad.

It frequently happens, that sums of money sent to the continent for subsidies and the like purposes, have their influence on the course of exchange, as it enables the merchants resident there to keep down the exchange, were they even obliged to remit over their balances in cash.

When England remits to Spain, Portugal, Italy, or any other kingdom or nation to which it gives the uncertain price, the lower the price of exchange is, the more it is to the advantage of England; as for instance, giving to Spain 35*d*. for their piastre or dollar, instead of giving 36*d*. to 38*d*. giving 60*d*. to Portugal for the milreis, instead of giving 66*d*. the same with Italy, &c. The contrary is to be observed in drawing.

When England remits to France, Holland, Hamburgh, Ireland, and all other places to which it gives the certain price, the higher the exchange is, the better: as for instance giving to France 1*l*. sterling for 26 livres, is better than 25 or 24 livres; giving to Holland 1*l*. sterling, for 36 schillings Flemish, is better than 35 or 34 schillings Flemish; or 112*l*. Irish for the 100*l*. sterling, than 108*l*. 6*s*. 8*d*. the par of exchange; the contrary to be observed in drawing.

It is to be remarked that the course of exchange governs the entire sum which is to be negotiated; and although it would appear at the place which gives the certain price, that the fluctuation falls altogether upon the other, yet it is not so, as it falls equally on both; for one may as well say that 100*l*. sterling is only equal to 106*l*. Irish, when the exchange is 6 per cent. (though the par is 108*l*. 6*s*. 8*d*.) as that 100*l*. sterling is equal in value to 112*l*. Irish, when the exchange is 12 per cent. and so of other exchanges. The certain price always falls or rises in its value, as the course is above or below par, and the uncertain price fluctuates in value the contrary way.

As banco money of Holland is always better than cash or current money, so there is usually a difference which is called the agio, and fluctuates from $1\frac{1}{8}$ to $5\frac{3}{8}$ per cent.

The exchanges on the continent are negotiated in the following manner, subject to the like fluctuations as before mentioned: viz.

From Amsterdam to London, from 30 to 40 schillings Flemish, per pound sterling.
to Paris, Bourdeaux, &c. from 50 to 60 groots Flemish, per ecu of 3 livres.
to Madrid, Cadiz, &c. from 90 to 100 ditto, per ducat of 375 marvedis plate.
to Lisbon, Porto, &c. from 40 to 50 ditto, per crusado, or crown of 400 reis.
to Genoa and Leghorn, from 80 to 90 ditto, per pezzo or dollar, of 5 livres banco at Genoa, or 6 livers at Leghorn.
to Hamburgh, from 30 to 40 stivers, per exchange ducat of 2 marks.
to Petersburgh, from 40 to 50 stivers current per rouble.

From Paris, Bourdeaux, &c. to London, from 20*d*. to 36*d*. per ecu, or crown of 3 livres.
to Amsterdam, from 50 to 60 groots Flemish, per ecu of ditto.
to Madrid, Cadiz, &c. from 13 to 17 livers, per doubloon, of 32 reals old plate.
to Lisbon, Porto, &c. from 4 to 500 reis per ecu.
to Genoa and Leghorn, from 90 to 100 sous, per dollar or pezzi of livres, 5.15 fuera banco at Genoa, or 6 livres at Leghorn.
to Hamburgh, from 25 to 28 schillings banco, per ecu of three livres.

From Naples to London, from 30*d*. to 50*d*. per ducato.

From Venice to London, from 40*d*. to 60*d*. per ducat of 24 grossi.

From Madrid, Cadiz, &c. to London, from 30*d*. to 40d. per peso or dollar of 8 reals old plate.
to Hamburgh, from 70 to 80 groots, per ducat of 375 marvedis.
to Amsterdam, from 90 to 100 groots Flemish, per ditto.
to Paris, Bourdeaux, &c. from 13 to 17 livres per doubloon of 32 reals old plate
to Lisbon, Porto, &c. from 2000 to 2200 reis, per doubloon old plate.
to Genoa, from 620 to 660 marvedis plate, per escudo d'ore marche.
to ditto, from 21 to 25 livres fuera banco, per pistole of 40 reals plata.
to Leghorn, from 120 to 130 pesos or Spanish dollars, for 100 pezzi or Leghorn dollars of 6 liras each.

From Lisbon and Porto to London, from 60*d*. 75*d*. per millrea.
to Amsterdam, from 40 to 50 groots Flemish per crusado of 400 reis.
to Paris, Bourdeaux, &c. from 450 to 500 reis per ecu of 3 livres.
to Madrid, &c. from 2000 to 2200 reis per doubloon, of 33 reals plata.
to Genoa and Leghorn, from 600 to 800 reis, per peso or dollar of livres 5.15 at Genoa, or 6 livres at Leghorn.
to Hamburgh, from 40 to 50 groots Flemish, per crusado of 400 reis.

From Genoa and Leghorn to London, from 40*d*. to 50*d*. per dollar or pezzo of 5 livres banco.
to Amsterdam from 80 to 90 groots Flemish, per ditto.
to Paris, Bourdeaux, &c. from 90 to 100 sols, per ditto.
to Madrid, from 620 to 660 marvedis plate, per escudo d'ore marche, (or 22 to 24 livres per pistole of 40 reals plata.)
to Cadiz from 120 to 130 pesos per 100 pezzi.
to Lisbon, Porto, &c. from 600 to 800 reis per dollar, of livres 5.15 fuero banco.

From Hamburgh to London, from 30 to 40 schillings Flemish per pound sterling.
to paris, Bourdeaux, &c. from 25 to 28 schillings bank, per ecu of 3 livres.
to Madrid, Cadiz, &c. from 60 to 80 groots, per ducat of 375 marvedis.
to Amsterdam, from 30 to 40 stivers, per 2 banco marks.
to Lisbon and Porto, from 40 to 50 groots Flemish, per crusado of 400 reis.
From Petersburgh to London, from 25*d.* to 40*d.* per rouble.
to Amsterdam, from 40 to 50 stivers per rouble.
to Hamburgh, from 25 to 35 schillings banco per rouble.

We shall now give some examples of the operations of exchange between London and those places with which she has a direct exchange.

Moneys of exchange and regulations with regard to London.

A pound = 20 shillings, or 240 pence.

A shilling = 12 pence, or 48 farthings.

Accounts are kept in pounds, shillings, and pence: some reckon farthings.

Value of usances for bills drawn from

France, Hamburgh, and Holland	1 month after date.
Portugal and Spain - -	2 months after date.
Italy - - - - -	3 months after date.

There are three days of grace, which begin the day after the bills are due, and on the third day they must be paid or protested. Bills due on Sunday must be paid or protested on Saturday: for those at sight, no days of grace are allowed.

LONDON.—*Course of Exchange.*

		Uncertain Prices.		Certain Prices.
Amsterdam	*giv.*	37 shillings Flemish	*for*	1 pound sterling.
Dublin	*giv.*	110½ pounds Irish	*for*	100 pounds British.
France	*giv.*	25 livres tournois	*for*	1 pound sterling.
Idem	*giv.*	25 francs	*for*	1 pound sterling.
Genoa	*rec.*	46 pence sterling	*for*	1 pezza fuori di banco.
Hamburgh	*giv.*	35 shillings Flemish	*for*	1 pound sterling.
Leghorn	*rec.*	50 pence sterling	*for*	1 pezza of 8 reals.
Naples	*rec.*	39 pence sterling	*for*	1 ducat di regno.
Portugal	*rec.*	63½ pence sterling	*for*	milreis.
Rotterdam	*giv.*	12 florins current	*for*	1 pound sterling.
Spain	*rec.*	36 pence sterling	*for*	1 dollar of exchange.
Venice	*giv.*	58 lire piccole	*for*	1 pound sterling.

N. B. As Bourdeaux and Bayonne exchange with London by francs, it is thought expedient to include the calculation of this exchange under the head of France.

London on Amsterdam.

Reduce 4086 florins 4 stivers 6 pennings banco into pounds, shillings, and pence sterling, at the exchange of 38 shillings 2 grotes Flemish banco per pound sterling.

Here 1 florin = 40 grotes
12 grotes = 1 shilling
38 shill. 2 grot. = 1 pound.

Rule.—Multiply 4086 4 6 by 40 grotes; divide the product by 38 2, price of exchange, and by 12 grotes.

```
 38  2          4086 4 6
 12               40
----           -------
458 div.       163440
   for 4 stivers     8
   for 6 penings     3/4
               -------
       458)163448 3/4(356 17 6 result by
                         common division.
```

N. B. When the price of exchange consists of shillings Flemish only, multiply the sum by 10 instead of 40, and multiply the price of exchange by 3 instead of 12.

London on Dublin.

Reduce 293 pounds 10 shillings 6 pence Irish into pounds, shillings, and pence British, at the exchange of 14 per cent.

114*l.* Irish = 100*l.* British.

Rule.—Multiply 293 10 6 by 100, and divide the product by 114, price of exchange.

```
           293 10 6
           100
          ------
          29300
for 10 shill.  50
for 6 pence     2 10
     114)29352 10(257 9 6 result by common division.
```

To prove this operation, that is, to calculate the exchange of Dublin on London, multiply 257 9 6 by 114, price of exchange, and divide the product by 100.

N. B. British money is 8⅓ per cent. better than the Irish; therefore

12 pounds British = 13 pounds Irish.

London on France.

Reduce 3222 livres 2 sols 9 deniers tournois into pounds, shillings, and pence sterling, at the exchange of 25 livres 14 sols tournois per pound sterling.

Here 25 liv. 14 sols = 1 pound.

Rule.—Divide 3222 2 9 by 25 14, price of exchange.

```
25 14          3222 2 9
20 fraction    20 fraction
-----          --------
514 div.   514)64442 15(125 7 6 result.
```

Reduce 2545 francs 41 cents into pounds, shillings, and pence sterling, at the exchange of 24 francs 80 cents per pound sterling.

Here 24 francs 80 cents = 1 pound.

Rule.—Divide 2545 41 by 24 80, price of exchange.

2480)254541(102 12 9 result.

London on Genoa.

Reduce 1277 pezze 13 soldi 4 denari fuori di banco into pounds, shillings, and pence sterling, at the exchange of 45 pence sterling per pezza of 115 soldi fuori di banco.

Here 1 pezza = 45 pence
240 pence = 1 pound.

Rule.—Multiply 1277 13 4 by 45, price of exchange, and divide the product by 240 pence.

```
            1277  13  4
              45
            ------------

London on Venice.

Reduce 14783 lire 3 soldi 9 denari piccole into pounds, shillings, and pence sterling, at the exchange of 59 lire piccole effective per pound sterling.

59 lire = 1 pound.

Rule.—Divide 14783 3 9 by 59, price of exchange.

59)14783 3 9(250 11 3 result.

We shall now give some other examples of the operations of exchange. First, between Holland and some places with which she has a direct exchange.

Amsterdam and Holland.

Moneys of Exchange, and Regulations.

A rixdollar (rixdalder) = 2½ florins = 50 stivers = 8⅓ shillings Flemish or 100 grotes Flemish.

A florin or guilder (gulden) = 20 stivers = 3⅓ shillings Flemish or 40 grotes Flemish.

A stiver (stuyver) = 16 penings or 2 grotes Flemish.

A pound Flemish (pond Flaams) = 20 shillings Flemish = 240 grotes Flemish or 6 florins.

A shilling Flemish (schilling Flaams) = 12 grotes Flemish or 6 stivers.

A grote Flemish (groot Flaams) = ½ stiver or 8 penings.

2 rixdollars = 5 florins
3 rixdollars = 25 shillings Flemish
3 florins = 10 shillings Flemish.

Accounts are kept in florins, stivers, and penings.

Value of usances for bills drawn from
England and France, 1 month after date.
Italy. Portugal, and Spain, 2 months after date.
Dantzic and Konigsberg, 40 a 70 days after date.
Germany and Switzerland 14 days after sight.

There are 6 days of grace, Sundays and holidays included, for bills of exchange drawn in current money; but for those drawn in bank money, no days of grace are generally allowed, and bills are protested on the second or third day after they become due.

AMSTERDAM and HOLLAND.—*Course of Exchange.*

The United States of America.

Moneys of exchange, and regulations.

A dollar = 100 cents.

Accounts are kept in dollars and cents.

Each dollar is rated at 4 shillings 6 pence sterling at par; therefore

40 dollars = 9 pounds sterling.

Course of Exchange.

Uncertain Prices. Certain Prices.

Amsterdam *rec.* 37 cents *for* 1 florin current.

Hamburgh *rec.* $33\frac{1}{2}$ cents *for* 1 marc lubs banco.

N. B. America exchanges with London at par, or at so much per cent. either above or under par. When the exchange is not at par, they reduce the sterling into dollars, and add, or deduct, according to the circumstance, the agio, that is, the difference between the par of exchange and the actual course.

Currencies, and their par in sterling.

A pound currency = 20 shillings or 240 pence.

In Georgia and South Carolina, a dollar is worth 4 shillings 6 pence currency; therefore

100 pounds currency = 100 pounds sterling.

In New England and Virginia, a dollar is worth 6 shillings currency; therefore

$133\frac{1}{3}$ pounds currency = 100 pounds sterling.

To reduce this currency into sterling, multiply by 3, and divide by 4.

In Delaware, Maryland, New Jersey, and Pennsylvania, a dollar is worth 7 shillings 6 pence currency; therefore

$166\frac{2}{3}$ pounds currency = 100 pounds sterling.

To reduce this currency into sterling, multiply by 3, and divide by 5.

In New York and North Carolina, a dollar is worth 8 shillings currency; therefore

$177\frac{7}{9}$ pounds currency = 100 pounds sterling.

To reduce this currency into sterling, multiply by 9, and divide by 16.

N. B. The several provincial currencies above mentioned are abolished in the United States of America, and the accounts kept in those moneys are not admitted in the courts of justice: they are still used, however, by the force of habit, in certain commercial transactions.

America on London.

Reduce 173 pounds 17 shillings 6 pence sterling into dollars and cents at par.

9 pounds = 40 dollars.

Rule.—Multiply 173 17 6 by 40 dollars, and divide the product by 9 pounds.

	173 17 6
	40
	6920
for 10 shillings	20

To prove this operation, multiply 803 1 6 by 100 pounds, and divide the product by 140, price of exchange.

Arbitration of EXCHANGES is a calculation, by combining the rates of exchange of two or more places, to draw therefrom that which shall be the most advantageous to remit or draw on. If bills remained always at par, or if the course of exchange was susceptible of being regulated with accuracy, there would be no such thing as an advantage to be obtained in one more than the other. The data to go upon are easily to be obtained, as the current prices are always published at short intervals.

The following examples will illustrate the nature of this subject.

London and Amsterdam.

Proportional Exchange.

	Quotation At London.	Quotation from Amsterdam.
On Amsterdam	37 3	
Genoa	45	$83\frac{1}{2}$
Hamburgh	35	34
Leghorn	$48\frac{1}{2}$	90
Lisbon	62	$44\frac{1}{2}$
Madrid	$34\frac{1}{2}$	$88\frac{1}{4}$
Paris	25 15	$53\frac{1}{2}$

Observation.—London gives the certain price to Amsterdam; that is, 1*l.* sterling for so many shillings Flemish banco, more or less; therefore, when London remits to Amsterdam, that place through which the highest course of exchange can be obtained is to be preferred, because more shillings Flemish will be received in exchange for one pound sterling. On the contrary, when London has to draw upon Amsterdam, that place should be chosen which furnishes the lowest course, because less shillings Flemish will be given in exchange for a pound sterling.

If you include the charges in the calculation, insert, for an indirect remittance, 100 in the divisor, and 100 less the charges in the dividend; and, for an indirect draft, place 100 in the divisor, and 100 more the charges in the dividend.

N. B. The above quotations are successively combined in the following arbitrations to ascertain the advantage which may be derived from the comparison of the differen t proportional exchanges.

London and Amsterdam through Genoa.

A bill on Genoa taken in London at 45 pence sterling per pezza of $5\frac{3}{4}$ lire fuori di banco is remitted to Amsterdam, and negotiated at $83\frac{1}{2}$ grotes Flemish banco per pezza fuori di banco; what is the proportional exchange between London and Amsterdam?

1 pound sterling	=	240 pence
45 pence	=	1 pezza
1 pezza	=	$83\frac{1}{2}$ grotes
12 grotes	=	1 shilling Flemish.

Rule.—Multiply 20, fixed number, by the course of exchange between Amsterdam and Genoa; and divide the product by the course of London on Genoa, that is,

$$\frac{20 \times 83\frac{1}{2}}{45} = 37\ 1\tfrac{1}{3}.$$

London on Amsterdam through Hamburgh.

A bill on Hamburgh taken in London at 35 shillings

Flemish banco per pound sterling is remitted to Amsterdam, and negotiated at 34 stivers banco for 2 marcs lubs banco: what is the proportional exchange between London and Amsterdam?

1 pound sterling	=	35 shillings Flemish
8 shillings Flemish	=	3 marcs
2 marcs banco	=	34 stivers banco
6 stivers	=	1 shilling Flemish.

Rule.—Multiply the course of exchange between London and Hamburgh by the course of Amsterdam on Hamburgh, and divide the product by 32, fixed number, that is, $\frac{35 \times 34}{32} = 37\ 2\frac{1}{4}$.

London and Amsterdam through Leghorn.

A bill on Leghorn taken in London at $48\frac{1}{2}$ pence sterling per pezza of 8 reals is remitted to Amsterdam, and negotiated at 90 grotes Flemish banco per pezza of 8 reals: what is the proportional exchange between London and Amsterdam?

1 pound sterling	=	240 pence
$48\frac{1}{2}$ pence	=	1 pezza
1 pezza	=	90 grotes
12 grotes	=	1 shilling Flemish.

Rule.—Multiply 20, fixed number, by the course of exchange between Amsterdam and Leghorn; and divide the product by the course of London on Leghorn.

$48\frac{1}{2}$	20
2 fraction	90
97 div.	1800
	2 fraction
	97)3600(37 $1\frac{1}{3}$

London and Amsterdam through Lisbon.

A bill on Lisbon taken in London at 62 pence sterling per milreis is remitted to Amsterdam, and negotiated at $44\frac{1}{2}$ grotes Flemish banco per crusade of 400 reis: what is the proportional exchange between London and Amsterdam?

1 pound sterling	=	140 pence.
62 pence	=	1000 reis
400 reis	=	$44\frac{1}{2}$ grotes
12 grotes	=	1 shilling Flemish.

Rule.—Multiply 50, fixed number, by the course of exchange between Amsterdam and Lisbon; and divide the product by the course of London on Lisbon, that is, $\frac{50 \times 44\frac{1}{2}}{62} = 35\ 10\frac{2}{3}$.

London and Amsterdam through Madrid.

A bill on Madrid taken in London at $34\frac{1}{2}$ pence sterling per dollar of exchange is remitted to Amsterdam, and negotiated at $88\frac{1}{4}$ grotes Flemish banco per ducat of exchange: what is the proportional exchange between London and Amsterdam?

1 pound sterling	=	240 pence
$34\frac{1}{2}$ pence	=	1 dollar
375 dollars	=	272 ducats
1 ducat	=	$88\frac{1}{4}$ grotes
12 grotes	=	1 shilling Flemish.

Rule.—Multiply 1088, fixed number, by the course of exchange between Amsterdam and Madrid; and divide the product by 75, fixed number, multiplied by the course of London on Madrid.

75	1088
$34\frac{1}{2}$	$88\frac{1}{4}$
300	8704
225	8704
$37\frac{1}{2}$	272

London and Amsterdam through Paris.

A bill on Paris taken in London at 25 livres 15 sols tournois per pound sterling is remitted to Amsterdam, and negotiated at $53\frac{1}{2}$ grotes Flemish banco for 3 francs: what is the proportional exchange between London and Amsterdam?

1 pound sterling	=	$25\frac{3}{4}$ livres tournois
81 livres tournois	=	80 francs
3 francs	=	$53\frac{1}{2}$ grotes
12 grotes	=	1 shilling Flemish.

Rule.—Multiply 20, fixed number, by the course of exchange between London and Paris, and by the course of Amsterdam on Paris; divide the product by 729, fixed number: that is $\frac{20 \times 25\frac{3}{4}}{729} = 37\ 9\frac{1}{2}$.

Recapitulation of the proportional exchange between London and Amsterdam.

Though	Genoa it comes out at	37	$1\frac{1}{3}$
	Hamburgh - -	37	$2\frac{1}{4}$
	Leghorn - -	37	$1\frac{1}{3}$
	Lisbon will answer to draw	35	$10\frac{2}{3}$
	Madrid	37	$17\frac{1}{16}$
	Paris will answer to remit	37	$9\frac{1}{2}$
Direct course between London and Amsterdam.		37	3

Application to remit.—It appears by the comparison of the above-mentioned exchanges, that the proportional exchange upon Paris is the highest, and consequently, that it would be more advantageous to remit to Amsterdam by that place than by either of the others, or by a direct bill. Such remittance would establish an indirect course of 37 $9\frac{1}{2}$, instead of the direct, 37 3; so that a merchant would receive 37 shillings $9\frac{1}{2}$ grotes Flemish in exchange for one pound sterling.

37 3 direct course: 37 $9\frac{1}{2}$			
indirect course : : 100 :			101 9 1
Less for charges, at $\frac{3}{4}$ per cent.	0 15 0	}	1 9 1
Advantages resulting from the arbitration	0 14 1		
			100 0 0

Application to draw.—If a merchant at London had to value on Amsterdam, instead of drawing directly, he would order his correspondent at Amsterdam to take a bill on Lisbon at $44\frac{1}{2}$, and either to remit it thither to provide for drafts from London upon Lisbon at 62, or to remit it to London to be negotiated at the same price. Such operation would establish an indirect course of 35 $10\frac{2}{3}$, instead of the direct, 37 3; so that a merchant

would give only 35 shillings $10\frac{2}{3}$ grotes Flemish for one pound sterling.

37 3 direct course: 35 $10\frac{2}{3}$						
indirect course : : 100*l.*:				96	6	10
Add for charges, at $\frac{3}{4}$ per cent.	0	15	0			
Advantages resulting from the arbitration	2	18	2	3	13	2
				100	0	0

London and Genoa.

Proportional exchange.

	Quotation at London.	Quotation from Genoa.
On Genoa - -	46	
Amsterdam - -	37 4	$84\frac{7}{8}$
Hamburgh - -	35 4	$46\frac{1}{4}$
Leghorn - - -	50	$124\frac{1}{2}$
Lisbon - - -	$61\frac{1}{2}$	765
Madrid - - -	$34\frac{3}{4}$	660
Paris - - -	25 2	$94\frac{5}{8}$

Observation.—London gives the uncertain price to Genoa; that is, 46 pence sterling, more or less, for one pezza fuori di banco; therefore, when London remits to Genoa, that place through which the lowest course of exchange can be obtained is to be preferred, because less pence will be given in exchange for one pezza. On the contrary, when London has to draw upon Genoa, that place should be chosen which furnishes the highest course, because more pence will be received in exchange for a pezza.

If you include the charges in the operation, insert, for an indirect remittance, 100 less the charges in the divisor, and 100 in the dividend; and, for an indirect draft, place 100 more the charges in the divisor, and 100 in the dividend.

N. B. The above quotations are successively combined in the following arbitrations to ascertain the advantage which may be derived from the comparison of the different proportional exchanges.

London and Genoa through Amsterdam.

A bill on Amsterdam taken in London at 37 shillings 4 grotes Flemish banco per pound sterling is remitted to Genoa, and negotiated at $84\frac{7}{8}$ grotes Flemish banco per pezza of $5\frac{3}{4}$ lire fuori di banco: what is the proportional exchange between London and Genoa?

1 pezza = $84\frac{7}{8}$ grotes
12 grotes = 1 shilling Flemish
$37\frac{1}{3}$ shill. Flemish = 1 pound sterling
1 pound sterling = 240 pence.

Rule.—Multiply 20, fixed number, by the course of exchange between Genoa and Amsterdam; and divide the product by the course of London on Amsterdam.

Exchange signifies also a place in most considerable trading cities, wherein the merchants, negotiants, agents, bankers, brokers, interpreters, and other persons concerned in commerce, meet on certain days, and at certain times, to confer and treat together of matters relating to exchanges, remittances, payments, adventures, assurances, freightments, and other mercantile negotiations, both by sea and land. These assemblies are held with so much exactness, that the absence of a merchant, &c. makes him suspected of drawing to a failure or bankruptcy, as not being able to stand the Change. The most considerable exchanges in Europe, are those of Amsterdam, and that of London, called the Royal Exchange.

Exchange of church livings, is where two persons having procured licence from the ordinary to treat of and exchange, do, by one instrument in writing, agree to exchange their benefices, being both spiritual, and in order thereunto resign them into the hands of the ordinary: such exchange being executed, the resignations are good. Wats. c. 4. These exchanges are now seldom used.

EXCHEQUER. This, which is a court of law and equity, is a very ancient court of record, established by William the Conqueror, as a part of the aula regis, though regulated and reduced to its present state by Ed. I. and intended principally to order the revenues of the crown, and to recover the king's debts and duties.

The court consists of two divisions, viz. the receipt of the exchequer, which manages the royal revenue: and

the judicial, which is again subdivided into a court of equity, and a court of common law.

The court of equity is held in the exchequer, before the lord treasurer, the chancellor of the exchequer, the chief baron, and three *puisne'* barons. The primary and original business of this court was to call the king's debtors to account, by bill filed by the attorney-general, and to recover any lands, tenements, or hereditaments, goods, chattels, or other profits or benefits, belonging to the crown.

This court, which was established merely for the benefit of the king's accountant, is thrown open; and now, by suggestion of privilege, any person may be admitted to sue here, as well as the king's accountant.

An appeal from the equity side of this court, lies immediately to the house of peers; but from the common law side, pursuant to 31 Ed. III. c. 12. a writ of error must first be brought into the court of exchequer chamber, whence, in the dernier resort, there lies an appeal to the house of lords.

Chancellor of the EXCHEQUER. See CHANCELLOR.

EXCHEQUER CHAMBER has no original jurisdiction, but is merely a court of appeal, to correct the errors of other jurisdictions; and consists of the lord chancellor, the lord treasurer, with the justices of the king's-bench and common-pleas. In imitation of this, a second court of exchequer chamber was erected by 27 Eliz. c. 8. consisting of the justices of the common-pleas, and the barons of the exchequer; before whom writs of error may be brought, to reverse judgments in certain suits commenced originally in the court of king's-bench. Into the exchequer chamber, are sometimes adjourned from the other courts, such causes, as the judges upon argument find to be of great weight and difficulty, before any judgment is given upon them to the court.

EXCHEQUER BILLS. Bills of credit, issued by the authority of parliament, payable with interest out of the produce of a particular tax, or more frequently out of the supplies to be granted in a future session. The sum of 2,750,000*l.* is usually raised in this manner on credit of the malt tax, and tax on personal estates, although it is well known that these taxes never produce so much, the deficiency being always made good out of the next supplies. The sum to be issued out of the produce of the consolidated fund is likewise usually raised by these bills, charged upon the growing produce of the surplus of the said fund; also other sums for ordinary and extraordinary expenses, by bills charged upon the first supplies of the next session; so that of late years the total amount of outstanding exchequer bills has usually been about ten millions. The bank, since 1706, have contracted with government for the circulation of these bills at a certain premium. The interest they carry has been at various rates, from *L.* 7 : 12 to 3 per cent.; those at present in circulation bear interest at the rate of three pence halfpenny a day per cent. which is computed up to the day of sale, from the respective dates of the bills. They are generally for 100*l.* each, but many of those issued on the vote of credit are for *l.*1000, and they have sometimes been made out for much larger sums: they are numbered arithmetically, and registered accordingly; for the purpose of paying them off in a regular course. They are paid at the exchequer bill office, and the time of payment is notified by advertisement.

The daily transactions between the bank and the exchequer are chiefly carried on by bills of 1000*l.* each, which are deposited by the bank in the exchequer to the amount of the sums received by them on government account; the bank notes and cash thus received by the bank being retained by them, as the detail part of the money-concerns of government is all transacted at the bank. The instalments on loans are paid into the receipt of the exchequer by these exchequer bills of 1000*l.* each, which are received again by the bank as cash, either for the amount of dividends due, or in re-payments of advances; and as, while deposited in the exchequer, they are considered merely as a pledge or security, they of course continue to bear interest, till the advance on which the bank first received them is paid off.

In October, 1796, the 5 per cent. exchequer bills, issued on the vote of credit, being at a considerable discount, it was thought proper to fund them; and the terms agreed upon were as follows:—The holders to be entitled for every 100*l.* to either of the following capitals:

l.	*s.*	*d.*	
176	19	$9\frac{3}{4}$	in the 3 per cents.
137	18	$7\frac{1}{4}$	in the 4 per cents.
118	6	$10\frac{1}{4}$	in the 5 per cents.

The amount of the bills thus funded was *l.* 33,870, and the capital stock created in the different funds, *l.* 2,374,333 14 8.

In November, 1801, it was again found necessary to fund a considerable part of the outstanding exchequer bills, which was effected on the following conditions: for each 100*l.* principal to receive the undermentioned proportions of stock:

l.		Estimated value. *l.*	*s.*	*d.*
25	Three per cent. consols	17	1	$10\frac{1}{2}$
25	Three per cent. reduced	16	16	$10\frac{1}{2}$
50	Four per cent. consols	42	7	6
25	New 5 per cents.	24	15	0
	1*s.* 9*d.* Long annuity	1	14	4
		l. 102	15	7

And the proprietors to have the liberty of subscribing 50*l.* additional in money for every 100*l.* they held in bills, the money thus raised to be applied in paying off the sum of about 2,400,000*l.* in exchequer bills in the possession of the bank. The amount of the bills funded and redeemed was 8,910,450*l.*

As there is always a considerable sum outstanding in exchequer bills, the interest paid thereon forms a constant addition to the annual charge of the funded debt; the amount paid for interest on exchequer bills in the years 1803, 1804, and 1805, respectively, was as follows:

	l.	*s.*	*d.*
1803 . .	801 787	10	$5\frac{1}{2}$
1804 . .	624.859	18	10
1805 . .	1.478.316	3	$3\frac{1}{2}$

The premium or discount at which exchequer bills sell, depends on the proportion which the interest payable on them bears to the interest produced by the public funds according to their current prices.

Exchequer bills, though the same in their nature and

solidity, differ in their origin from navy bills in this, that they are issued in anticipation of revenue, and circulated by the bank of England to raise money. During the recess of parliament, there is a sum left to the credit of the chancellor of the exchequer, to serve in cases of exigency. The bank makes advances to the amount voted, for which the exchequer issues bills. There is a standing contract between goverment and the bank for the trouble and expense attending the issue and circulation of these bills. Notice is given by public advertisement, and the payment is made at the exchequer-bill office Westminster.

EXCHEQUER, *black book of the*, a book containing a description of the court of England in 1175, and its officers, with their ranks, wages, privileges, perquisites, &c. also the revenues of the crown, both in money and cattle. Here we find that for one shilling as much bread might be bought as would serve 100 men a whole day; that the price of a fat bullock was only 12 shillings, and a sheep less than four.

EXCISE, one of the principal branches of the public revenue, consisting of inland duties, or taxes on articles manufactured or consumed, whereas the duties of customs are paid on goods brought into or carried out of the country. Excise duties are of very ancient date; they were numerous among the Romans, and were established in Italy, Spain, France, and Holland, long before they were known in this country. The first attempt to introduce this species of taxation into England was in the year 1626, but it was not actually established till 1643, when the long parliament laid an excise duty on beer, ale, and other liquors, with a solemn declaration that at the end of the war all excises should be abolished. The example was immediately followed by the king and parliament of Oxford, who established similar excise duties, and the contest continuing longer than was expected, this mode of levying money was extended to bread, meat, salt, and many other necessary articles. The excise on bread and meat was afterwards repealed, but the duties on beer and ale were continued, and after the Restoration were granted to Charles 2d, during his life; from whose death they were continued, under the title of the *temporary excise*, to the different sovereigns, during their respective lives, as a part of the civil list revenue; but they are now placed on the same footing as all the other permanent taxes, being made perpetual, and the produce carried to the consolidated fund. The *hereditary excise* was a duty of fifteen pence per barrel upon beer and ale, and a proportionate sum upon other liquors sold in the kingdom, and was granted to Charles 2d, his heirs and successors for ever, as a compensation for the profits of the feudal privileges of wardship and purveyance then abolished by act of parliament. These two branches, which comprehend all the excise duties existing at the Revolution, produced on an average 610,486*l.* yearly. During the reign of William 3d, the excise was extended to salt, additional duties were laid on beer and ale, and an excise duty on malt, which has since been granted annually, was established. In the reign of queen Anne, candles, hides and skins, vellum and parchment, paper and pasteboards, soap, starch, hops, and some other articles, were subjected to excise duties. In the reign of George 1st, the excise duties, with all other taxes which had been granted for terms of years, were made perpetual, a duty was laid on wrought plate, and the principal part of the duties on tea, coffee, and chocolate, was transferred from the customs to the excise. During the reign of George 2d, considerable additions were made to the excise duties, by licences, a duty on glass, and new duties on spirituous liquors, coffee, chocolate, and malt; an attempt was made by sir R. Walpole to transfer the duties on wines and tobacco from the customs to the excise, but the measure being thought introductory to a general excise, it experienced great opposition, and was abandoned. Since that period, numerous additional duties have been imposed on all the articles subject to the excise, with which the increased consumption caused by the progress of population and luxury, has rendered this source of revenue so productive, that it is not surprising those who have had the management of the public finances should have become partial to it, though it has always been an obnoxious mode of taxation to the public. The total gross amount raised in England by excise duties, in the year ending 5th of January, 1805, will appear by the following account.

Auctions	*l.* 181,126

licences	71,324
	l. 1,384,873

In England the excise duties are collected at an expense of only 2*l.* 16*s.* 1*d.* per cent. on the gross revenue, or 3*l.* 4*d.* per cent. on the net produce; but the expense of collection in Scotland amounts to 7*l.* 8*s.* 6*d.* per cent. on the gross revenue, or 3*l.* 10*s.* 6*d.* per cent. on the net produce. In Ireland the management of the excise duties is united with the customs, and the expense of the whole amounts to 11*l.* 3*s.* 3*d.* per cent. on the net revenue.

Excise Laws. For more easily levying the revenue of the excise, the kingdom of England and Wales is divided into about fifty collections, some of which are called by the names of particular counties, others by the names of great towns; where one county is divided into several collections, or where a collection comprehends the contiguous parts of several counties, every such collection is subdivided into several districts, within which there is a supervisor; and each district is again subdivided into outrides and footwalks, within each of which there is a gauger or surveying officer.

The commissioners or sub-commissioners, in their respective circuits and divisions, shall constitute, under their hands and seals, so many gaugers as they shall find needful.

Arrears of duties.—By several acts of parliament, all articles in the possession of persons subject to the excise laws, together with all the materials and utensils of whatsoever description, are made liable for the arrears of duties, whether these be single or double duties; and if a trader, being in arrears for the single duties, becomes a bankrupt, and is convicted after the assignment of his effects, the double duties are a lien upon the exciseable commodities, utensils, and materials in the hands of his assignees, and the commissioners or magistrates may authorize the penalty to be levied upon all such commodities, and all the materials, preparations, utensils, and vessels for making thereof, in the custody of the bankrupt, or any person or persons in trust for him. 2 Doug. 411.

Bonds, for the exportation of exciseable commodities, are to be taken by officers of excise, and they are to be given generally upon all exciseable articles, at the place where exported.

Forgery of any stamps, licences, certificates, permits, or any other excise documents, is by various statutes made a capital felony.

Licences.—In all cases where licences are required, the licence will only sanction the business carried on in that particular place for which such licence was granted; but when the business is carried on by partners, one licence will be sufficient to cover the firm.

Officers of excise.—The officers of excise are to be appointed, and may be dismissed, replaced, or altered, by the commissioners, under their hands and seals; their salaries are allowed and established by the treasury; and by 1 W. & M. c. 24. s. 15. if it is proved by two witnesses, that any officer has demanded or taken any money, or other reward whatever, except of the king, such offender shall forfeit his office.

By several statutes, no process can be sued out against any officer of excise, for any act done in the execution of his office, until one month after notice given, specifying the cause of action, and the name and abode of the person who is to begin, and the attorney who is to conduct the action; and within one month after such notice, the officer may tender amends, and plead such tender in bar; and having tendered insufficient or no amends, he may, with leave of the court, before issue joined, pay money into court.

Officers of excise are empowered to search, at all times of the day, entered warehouses, or places for tea, coffee, &c. But private houses can only be searched upon oath of the suspicion before a commissioner or justice of peace, who can by their warrant authorize a search.

Permits. Persons dealing in exciseable commodities are entitled to permits for removing the same to different places in certain quantities, and under certain regulations. These permits are written upon a peculiar species of paper, manufactured expressly for the purpose; and by 23 Geo. III. c. 70. s. 11. no permit paper is to be delivered out before it shall be filled up agreeably to the request note of a trader; and officers knowingly granting any false permit, making false entries in the counterpart thereof, or receiving any commodities into stock with a false or forged permit, are to be transported for seven years.

Samples.—Officers of excise are, by various acts, empowered to take samples of exciseable commodities, paying the prices therein regulated for the same.

Seizures.—When an officer makes a seizure of any spirits, or other articles, he must lay his hand on the casks, vessels, &c. so seized, and declare that he seizes such spirits, &c. and the casks or vessels containing the same, for the use of his majesty and of himself; but if the officer happens to be alone when he makes such seizure, he must afterwards, in the presence of witnesses, again lay his hand on such cask, vessel, &c. and repeat the former declaration of seizure.

All informations on seizures must be laid in the names of the officers making the same.

By 41 Geo. III. c. 96. commissioners of excise are empowered to make restitution of exciseable goods.

Scales and weights.—By various acts of parliament, traders subject to the excise laws are to keep just and sufficient scales and weights, under penalty of 100*l.* for every such offence, and the scales and weights may be seized by the officer.

Traders, manufacturers, and dealers liable to excise duties, are to assist the officers in weighing stock; and forcibly obstructing, or using any art or contrivance to prevent or impede the officers from taking a true account incurs a penalty of 100*l.*

EXCLAMATION, in rhetoric, a figure that expresses the violent and sudden breaking out, and vehemence of any passion. Such is that in the second book of Milton's Paradise Lost:

> O unexpected stroke, worse than of death!
> Must I thus leave thee, Paradise? Thus leave
> Thee, native soil; these happy walks and shades,
> Fit haunt of gods?

EXCLUSION, *or bill of exclusion*, a bill proposed about the close of the reign of king Charles II. for excluding the duke of York, the king's brother, from the throne, on account of his being a papist.

EXCLUSION, in mathematics, is a method of coming at the solution of numerical problems, by previously throwing out of our consideration such numbers as are of no use in solving the question.

EXCOECARIA, a genus of the triandria order, in the diœcia class of plants; and in the natural method ranking under the 38th order, tricoccæ. The male amentum is naked; there is no calyx nor corolla; there are three styles, and a tricoccous capsule. There are two species. The agallocha, or aloes-wood, is a native of China and some of the Indian islands, and is about the same height and form as the olive-tree. Its trunk is of three colours, and contains three sorts of wood; the heart is that of tambac, or calombac, which is dearer in the Indies than even gold itself. It serves to perfume clothes and apartments; and is esteemed a sovereign cordial in fainting fits, a restorative in the palsy, and a cure for ascarides in children. It is burnt as incense in the Chinese and Indian temples; and it is also used to set the most precious jewels that are wrought in the Indies.

The aloes-wood is very highly valued; and strange fables were invented as to the origin of the tree that yields it; some pretending that it grew in Paradise, and was only conveyed to us by means of the rivers overflowing their banks and sweeping off the trees in their way; others affirming that it grew on inaccessible mountains, where it was guarded by certain wild beasts, &c. The Siamese ambassadors to the court of France in 1686, who brought a present of this wood from their emperor, gave the Europeans the first consistent account of it.

EXCOMMUNICATION, an ecclesiastical penalty or censure whereby such persons as are guilty of any notorious crime or offence, are separated from the communion of the church, and deprived of all spiritual advantages.

Excommunication among the Jews, according to Elias, a German rabbin, was distinguished into three kinds: 1. Niddui, which was a separation of but a few days. 2. Cherem, a separation attended with execration and malediction. And, 3. Shammatha, which was the last and greater excommunication. But Selden says, that niddui and shammatha are the same thing, and therefore that there were but two kinds of excommunication among the Jews, viz. the greater and the less. They made also another distinction in excommunication, into total or universal, by which a man was excommunicated with regard to all men; and partial, by which a man was excommunicated in one city, and with regard to certain persons, and not others.

It is observable, that not only the judges had the power of excommunicating, but that each particular per-

son in conversation might excommunicate another, and himself likewise; and this excommunication, if well-grounded, was of force; nay, if a man dreamed that he was excommunicated by himself or by another, he was considered as an excommunicated person, because this dream was supposed to be sent from God.

As to the effects of the Jewish excommunication, the lesser excluded the excommunicated person from the society of men; that is, he was not to come nearer them than four cubits, neither he, his wife, children, or domestics, according to Buxtorf. The greater absolutely sequestered the person from the conversation of others; and sometimes he was shut up in a small chamber or prison, where he lived alone. Baronius and Beza pretend, that the greater excommunication excluded men from the use of sacred things. Selden, on the contrary, affirms, that they were allowed to be present in the temple, and partake of the public worship. Buxtorf, who is of the same opinion, adds, that whereas others came into the temple at the right hand, and went out at the left, the excommunicated were obliged both to go in and out at the left.

Excommunication among the modern Jews, is attended with the most terrible consequences. The excommunicated person is refused all human assistance: if there is a corpse in his house, or a child to be circumcised, none must help him. He is cursed by the book of the law, by the curse of Joshua against Jericho, by that of Elisha against the children, by heaven and earth, and God is besought that a wirldwind may dash him to pieces. He is pelted with stones if he appears in the streets; and if he obtains absolution, it is upon the most mortifying conditions; for he is publicly tied to a post and whipped, after which he lays himself down at the door of the synagogue, and all those who go out, pass over him. This was the very case of the famous Jew Acosta. See Bayle, in the article Acosta.

In the ancient christian church, the power of excommunication, as well as other acts of ecclesiastical discipline, was lodged in the hands of the clergy; who distinguished it into the greater and lesser. The lesser excommunication, simply called αφοριςμος, separation or suspension, consisted in excluding men from the participation of the eucharist, and the prayers of the faithful. But they were not expelled the church; for they had the privilege of being present at the reading of the scriptures, the sermons, and the prayers of the catechumens and penitents. This excommunication was inflicted for lesser crimes, such as neglecting to attend the service of the church, and misbehaviour in it.

The greater excommunication, called παντελης αφοριςμος, total separation and anathema, consisted in an absolute and entire exclusion from the church and the participation of all its rites. When any person was thus excommunicated, notice was given of it by circular letters to the most eminent churches all over the world, that they might all confirm this act of discipline, by refusing to admit the delinquent to their communion. The consequence of this latter excommunication was very terrible. The excommunicated person was avoided in civil commerce and outward conversation. No one was to receive him into his house, nor eat at the same table with him; and when dead, he was denied the solemn rites of burial. It has been a question, whether the ancient church used to add execration to her censures. Grotius thinks this was done, though very seldom, as in the case of Julian the apostate, for whose destruction the ancient christians absolutely prayed to God. St. Chrysostom was utterly against this practice, affirming that we ought not to pray against the sinner, but against his opinions or actions.

The Romish pontifical takes notice of three kinds of excommunication: 1. The minor, incurred by those who have any correspondence with an excommunicated person. 2. The major, which falls upon those who disobey the commands of the holy see, or refuse to submit to certain points of discipline; in consequence of which they are excluded from the church militant and triumphant, and delivered over to the devil and his angels. 3. Anathema, which is properly that pronounced by the pope against heretical princes and countries. In former ages, these papal fulminations were most terrible things; but at present, they are formidable to none but a few petty states of Italy.

Excommunication, in the Greek church, cuts the offender off from all communion with the 318 fathers of the first council of Nice, and with the saints; consigns him over to the devil and the traitor Judas; and condemns his body to remain after death as hard as a flint, or a piece of steel, unless he humbles himself and makes atonement for his sins by a sincere repentance. The former abounds with dreadful imprecations; and the Greeks assert, that if a person dies excommunicated, the devil enters into the lifeless corpse; and, therefore, in order to prevent it, the relations of the deceased cut his body in pieces, and boil them in wine. It is a custom for the patriarch of Jerusalem annually to excommunicate the pope and the church of Rome; on which occasion, together with a great deal of idle ceremony, he drives a nail into the ground with a hammer, as a mark of malediction.

Excommunication, among the pagans, excluded the person from the sacrifices and the temples, and delivered him over to the Furies, which was called execrare, and Diris devovere. When Marcus Crassus set out on his expedition against the Parthians, Atteius, tribune of the people, not being able to prevent him, ran to the gate of the city through which the general was to pass, and setting a chaffing-dish in the middle of the way with fire in it, when Crassus drew near, he threw some perfumes into the chaffing-dish, and pronounced curses against Crassus with great exclamation, and thus excommunicated him.

Excommunication, in the church of England, is the highest ecclesiastical censure which can be pronounced by a spiritual judge against a christian; for thereby he is excluded from the body of the church, and disabled to bring any action, or sue any person in the common law courts. Co. Lit. 133.

The sentence of excommunication was instituted originally for preserving the purity of the church; and it seems agreed, that wherever the spiritual court has jurisdiction in any cause, and the party refuses to appear to their citation, or after sentence, being admonished to obey their de ree, that he may be excommunicated. 1 Rol. Abr. 883.

A person excommunicated is disabled to be a witness

in any cause: he cannot be attorney or procurator for another; he is to be turned out of the church by the church-wardens, and not to be allowed christian burial. Gibs. Cod. 135.

The sentence of excommunication can only be pronounced by the bishop, or other person in holy orders, being a master of arts at least; also the priest's name pronouncing such sentence, is to be expressed in the instrument issuing under seal out of the court. Gibs. Cod. 1095.

EXCOMMUNICATO CAPIENDO, a writ directed to the sheriff, for apprehending him who stands obstinately excommunicated, forty days; for such an one not seeking absolution, has, or may have, his contempt certified into the chancery; whence issues this writ, for imprisoning him without bail or mainprize until he conforms. 5 Eliz. c. 23.

EXCOMMUNICATO DELIBERANDO, a writ to the sheriff, for the delivery of an excommunicated person out of prison, upon certificate of the ordinary, of his conformity to the jurisdiction ecclesiastical. F. N. B. 63.

EXCOMMUNICATO RECIPIENDO, a writ whereby persons excommunicated, being for their obstinacy committed to prison, and unlawfully delivered thence, before they have given caution to obey the authority of the church, are commanded to be sought for and imprisoned again.

EXCORIATION, in medicine and surgery, the galling or rubbing off of the cuticle.

EXCRESCENCE, in surgery, denotes every preternatural tumour which arises upon the skin, either in the form of a wart or tubercle. If they are born with a person, as they frequently are, they are called navi materni, or marks from the mother; but if the tumour is large, so as to depend from the skin like a fleshy mass, it is then called a sarcoma. See SURGERY.

EXCRETION, or SECRETION, in medicine, a separation of some fluid, mixed with the blood, by means of the glands. See PHYSIOLOGY.

EXCRETORY, in anatomy, a term applied to certain little ducts or vessels, destined for the reception of a fluid, secreted in certain glandules, and other viscera, for the excretion of it in the appropriated places. See ANATOMY.

EXECUTION is a judicial writ, grounded on the judgment of the court whence it issues; and is supposed to be granted by the court at the request of the party at whose suit it is issued, to give him satisfaction on the judgment which he has obtained: and therefore an execution cannot be sued out in one court, upon a judgment obtained in another. Impey, K. B.

Executions in actions where money is recovered, as a debt or damages, are of five sorts: 1. against the body of the defendant; 2. against his goods or chattels; 3. against his goods and the profits of his lands; 4. against the goods and the possession of his land; 5. against all three, his body, lands, and goods. 3 Black, 414. See CAPIAS AD SATISFACIENDUM, FIERI FACIAS, LEVARI FACIAS, and ELEGIT.

EXECUTION *of criminals*, must be according to the judgment; and the king cannot alter a judgment from hanging to beheading, because no execution can be warranted, unless it is pursuant to the judgment. 3 Inst. 52.

Execution of criminals is the completion of human punishment; and this in all cases, as well capital as otherwise, must be performed by the legal officer, the sheriff or his deputy. 4 Black. 405.

EXECUTIONE FACIENDA IN WITHERNAMIUM, a writ that lies for taking his cattle who formerly had conveyed out of the county the cattle of another: so that the bailiff, having authority from the sheriff to replevy the cattle so conveyed away, could not execute his charge.

EXECUTIONE JUDICII, a writ which lies where judgment is given in any court of record, and the sheriff or bailiff neglecting to do execution of the judgment, the party shall then have this writ directed to the said sheriff or bailiff; and if they shall not do execution, he shall have an alias, and pluries. And if upon this writ execution is not done, or some reasonable cause returned why it is delayed, the judges of the court may amerce them.

EXECUTOR, is a person appointed by the testator, to carry into execution his will and testament after his decease. The regular mode of appointing an executor, is by naming him expressly in the will; but any words indicating an intention of the testator to appoint an executor will be deemed a sufficient appointment.

Any person capable of making a will, is also capable of being an executor: but in some cases, persons who are incapable of making a will, may nevertheless act as executors, as infants, or married women; to obviate, however, inconveniences which have occurred respecting the former, it is enacted by stat. 38 Geo. III. c. 89, that where an infant is sole executor, administration, with the will annexed, shall be granted to the guardian of such infant, or such other person as the spiritual court shall think fit, until such infant shall have attained the age of twenty-one; when, and not before, probate of the will shall be granted him.

An executor derives his authority from the will and not from the probate, and is therefore authorized to do many acts in execution of the will, even before it is proved, such as releasing, paying, or receiving of debts, assenting to licences, &c. but he cannot proceed until he has obtained probate.

If an executor dies before probate, administration must be taken out with the will annexed; but if an executor dies, his executor will be executor to the first testator, and no fresh probate will be needed. It will be sufficient if one only of the executors prove the will; but if all refuse to prove, they cannot afterwards administer, or in any respect act as executors.

If an executor becomes a bankrupt, the court of chancery will appoint a receiver of the testator's effects, as it will also upon the application of a creditor, if he appears to be wasting the assets.

If an executor once administers, he cannot afterwards renounce; and the ordinary may in such case issue process to compel him to prove the will. 1 Mod. 213.

If an executor refuses to take upon him the execution of the will, he shall lose the legacy therein contained.

If a creditor constitutes his debtor his executor, this is at law a discharge of the debt, whether the executor acts or not, provided however there be assets sufficient to discharge the debts of the testator.

The first duty of an executor or administrator is to bury the deceased in a suitable manner; and if the execu-

tor exceeds what is necessary in this respect, it will be a waste of the substance of the testator.

The next thing to be done by the executor is to prove the will, which may be done either in the common form, by taking the oath to make due distribution, &c. or in a more solemn mode, by witnesses to its execution.

By stat. 37 Geo. III. c. 9. s. 10, every person who shall administer the personal estate of any person dying without proving the will of the deceased, or taking out letters of administration within six calendar months after such person's decease, shall forfeit 50*l*.

Upon proving the will, the original is to be deposited in the registry of the ordinary, by whom a copy is made upon parchment under his seal, and delivered to the executor or administrator, together with a certificate of its having been proved before him, and this is termed the probate.

If all the goods of the deceased lie within the same jurisdiction, the probate is to be made before the ordinary or bishop of the diocese, where the deceased resided; but if he had goods and chattels to the value of 5*l*. in two distinct dioceses or jurisdictions, the will may be proved before the metropolitan or archbishop of the province in which the deceased died.

An executor, by virtue of the will of the testator, has an interest in all the goods and chattels, whether real or personal, in possession or in action of the deceased; and all goods and effects coming to his hands will be the assets to make him chargeable to creditors and legatees.

An executor or administrator stands personally responsible for the due discharge of his duty; if, therefore, the property of the deceased is lost, or through his wilful negligence becomes otherwise irrecoverable, he will be liable to make it good; and also where he retains money in his hands longer than is necessary, he will be chargeable not only with interest but costs, if any have been incurred.

But one executor shall not be answerable for money received, or detriment occasioned by the other, unless it has been by some act done between them jointly.

An executor or administrator has the same remedy for recovering debts and duties, as the deceased would have had if living.

Neither an executor nor administrator can maintain any action, for a personal injury done to the deceased, when such injury is of such a nature for which damages may be received; in actions however, which have their origin in breach of promise, although the suit may abate by the death of the party, yet it may be revived either by his executors or administrators, who may also sue for rent in arrear, and due to the deceased in his life time.

By the custom of merchants, an executor or administrator may indorse over a bill of exchange or promissory note.

An executor or administrator may also, on the death of a lessee for years, assign over the lease, and shall not be answerable for rent after such assignment; nor shall he be liable for rent due after the lessee's death, from premises which in his life-time he had assigned to another.

An executor or administrator is bound only by such covenants in a lease as are said to run with the land.

The executor or administrator, previous to the distribution of the property of the deceased, must take an inventory of all his goods and chattels, which must, if required, be delivered to the ordinary upon oath.

He must then collect, with all possible convenience, all the goods and effects contained in such an inventory; and whatever is so recovered that is of a saleable nature, and can be converted into money, is termed assets, and makes him responsible to such amount to the creditors, legatees, and kindred of the deceased.

The executor or administrator having collected in the property, is to proceed to discharge the debts of the deceased, which he must do according to the following priorites, otherwise he will be personally responsible.

1. Funeral expenses, charges of proving the will, and other expenditures incurred by the execution of his trust.

2. Debts due to the king on record, or by speciality.

3. Debts by particular statutes, as by 30 C. II. c. 23. Forfeitures for not burying in woollen, money due for poor-rates, and money due to the post-office.

4. Debts of record, as judgments, statutes, recognizances, and those recognized by a decree of a court of equity; and debts due on mortgage. 3 Peere Wms. 401.

5. Debts on special contracts, as bonds or other instruments under seal, and also rent in arrear.

6. Debts on simple contract, viz. such as debts arising by mere verbal promise, or by writing, not under seal, as notes of hand, servants' wages, &c.

The executor is bound at his peril to take notice of debts on record, but not of other special contracts, unless he receives notice.

If no suit is actually commenced against an executor or administrator, he may pay one creditor in equal degree the whole debt, though there should be insufficient remaining to pay the rest; and even after the commencement of a suit, he may by confessing judgment to other creditors of the same degree, give them a preference.

Executors and administrators are also allowed, amongst debts of equal degree, to pay themselves first: but they are not allowed to retain their own debt, to the prejudice of others in a higher degree; neither shall they be permitted to retain their own debts, in preferance to that of their co-executor or co-administrator of equal degree, but both shall be charged in equal proportion.

A mortgage made by the testator must be discharged by the representative out of the personal estate, if there is sufficient to pay the rest of the creditors and legatees. Where such mortgage, however, was not incurred by the deceased, it is not payable out of the personal estate. See LEGACIES, and ASSETS.

EXECUTOR *de son tort*, or an executor of his own wrong, a person that takes upon him the office of an executor by intrusion, without being so constituted by the testator, or appointed by the ordinary to administer. Such a person is chargeable to the rightful executor, as also to all the testator's creditors and legatees, so far as the goods amount to which he wrongfully possessed.

EXECUTORY ESTATE. Estates executory, are when they pass presently to the person to whom conveyed, without any after-act, 2 Inst. 513; and leases for years, rents, annuities, conditions, &c. are called inheritances executory. Id. 293.

EXECUTORY *devise*, is defined a future interest, which

cannot vest at the death of a testator, but depends upon some contingency which must happen before it can vest. Abr. Eq. 186.

An executory devise differs from a remainder, in three very material points: 1. That it needs not any particular estate to support it. 2. That by it a fee-simple, or other less estate, may be limited after a fee-simple. 3. That hereby a remainder may be limited of a chattel interest, after a particular estate for life created in the same. 2 Black. 172.

Executory devises of terms for years.—If a farmer devises his term to A for life, the remainder to another, though A have the whole estate (for that is in him during his life) and so no remainder can be limited over, at common law, yet it is good by way of executory devise. 1 Rol. Abr. 610.

EXEDRÆ, in antiquity, a general name for such buildings as were distinct from the main body of the churches, and yet within the limits of the church taken in its largest sense. Among the exedræ the chief was the baptistery. Exedræ were also halls of little academies with several seats, upon which philosophers, rhetoricians, &c. sat when they met for conversation or disputation. Vitruvius speaks of them as places very open and exposed to the sun.

EXEGESIS, a discourse by way of explanation or comment upon any subject. In the Scotch universities there is an exercise among the students in divinity called an exegesis, in which a question is stated by the respondent, who is then opposed by two or three other students in their turns; during which time the professor moderates, and solves the difficulties which the respondent cannot overcome.

EXEMPLIFICATION *of letters patent*, a transcript or duplicate of them, made from the enrolment thereof, and sealed with the great seal. These exemplifications are by statute equally effectual, and may be pleaded as well as the originals. One may exemplify a patent under the great seal in chancery; also any record or judgment in any of the courts at Westminster, under the seal of each court; which exemplifications may be given in evidence to a jury. It is held, that nothing but matter of record ought to be exemplified.

EXEMPTION, in law, a privilege to be free from some service or appearance: thus; barons and peers of the realm are, on account of their dignity, exempted from being sworn upon inquests; and knights, clergymen, and others, from appearing at the sheriff's tourn. Persons of seventy years of age, apothecaries, &c. are also by law exempted from serving on juries; and justices of the peace, attorneys, &c. from parish-offices.

Exemption, in the church of Rome, a privilege granted by the pope to the clergy, and sometimes to the laity, to exempt or free them from the jurisdiction of their respective ordinaries. Thus monasteries, and even private priests, for a small charge formerly procured exemptions from the jurisdiction of their bishops. In this, however, the council of Trent made a small reformation, by abolishing the exemption of particular priests, and monks not living in cloisters, and that of chapters in criminal matters.

EXERCISE, among physicians, such an agitation of the body as produces salutary effects in the animal œconomy. See Medicine.

Exercise, in military affairs, is the practice of all those motions and actions, together with the whole management of arms, which a soldier is to be perfect in, to render him fit for service, and make him understand how to attack and defend. Exercise is the first part of the military art; and the more it is considered, the more essential it will appear. It disengages the human frame from the stiff rusticity of simple nature, and forms men and horses to all the evolutions of war. The honour, merit, appearance, strength, and success of a corps, depend wholly upon the attention which has been paid to the drill and exercise of it, according to prescribed rules and regulations; while on the other hand we see the greatest armies, for want of being exercised, instantly disordered, and that disorder increasing in spite of command; the confusion oversets the art of skilful masters, and the valour of the men only serves to precipitate the defeat; for which reason it is the duty of every officer to take care that the recruits be drilled as soon as they join the corps.

The greatest advantage derived from exercise, is the expertness with which men become capable of loading and firing, and their learning an attention to act in conformity with those around them. It has always been lamented, that men have been brought on service, without being informed of the uses of the different manœuvres they have been practising; and that having no ideas of any thing but the uniformity of the parade, they instantly fall into disorder and confusion when they lose the step, or see a deviation from the straight lines they have been accustomed to at exercise. It is a pity to see so much attention confined to show, and so little given to instruct the troops in what may be of use to them on service. Though the parade is the place to form the characters of soldiers, and to teach them uniformity, yet when confined to that alone, it is too limited and mechanical for a true military genius.

The great loss which the British troops sustained in Germany, America, and the West Indies, during a former war, from sickness, and not from the enemy, was chiefly owing to a neglect of exercise. An army whose numbers vanish after the first four months of a campaign, may be very ready to give battle in their existing period; but the fact is, that although fighting is one part of a soldier's business, yet bearing fatigue, and being in health, is another, and at least as essential as the first. A campaign may pass without a battle, but no part of a campaign can be gone through without fatigue, without marches, without an exposure to bad weather; all of which have exercise for their foundation; and if soldiers are not trained and inured to these casualties, but sink under them, they become inadequate to bodily fatigue, and eventually turn out a burthen to their country.

It is not from numbers, or from inconsiderate valour, that we are to expect victory; in battle it commonly follows capacity, and a knowledge of arms. We do not see that the Romans made use of any other means to conquer the world, than a continual practice of military exercises, an exact discipline in their camps, and a constant attention to cultivate the art of war. Hence, both ancients and moderns agree, that there is no other way to form

good soldiers but by exercise and discipline; and it is by a continual practice and attention to this, that the Prussians arrived at that point of perfection which has been so much admired in their evolutions, and manual exercise.

Formerly in the British service every commander in chief, or officer commanding a corps, adopted or invented such manœuvres as he judged proper, excepting in the instance of a few regulations for review; neither the manual exercise, nor quick and slow marching, were precisely defined by authority. In consequence, when regiments from different parts of the kingdom were brigaded, they were unable to act in line till the general officer commanding had established some temporary system to be observed by all under his command.

These inconveniences were at length obviated by the rules and regulations compiled by general Dundas on the system of the Prussian discipline, as established by Frederic the Great.

By his majesty's orders issued in 1792, this system is directed to be "strictly followed and adhered to, without any deviation whatsoever. And such orders before given, as are found to interfere with, or counteract their effect and operation, are to be considered as cancelled and annulled."

Exercise *of the infantry*, includes the use of the firelock and practice of the manœuvres for regiments of foot, according to the regulations issued by authority.

When a regiment of foot is drawn up, or paraded for exercise, the men are placed two, and sometimes three deep, which latter is the natural formation of a battalion. The grenadiers are on the right, and the light infantry on the left. In order to have the manual exercise well performed, it is in a particular manner requisite, that the ranks and files be even, well dressed, and the file-leaders well covered; this must be very strictly attended to both by the major and his adjutant; all officers also, on service in general, where men are drawn up under arms, or without, must be careful that the ranks and files are exactly even, and the soldiers must learn to dress themselves at once, without the necessity of being directed to do it. The beauty of all exercise and marching consists in seeing a soldier carry his arms well, keep his firelock steady and even in the hollow of his shoulder, the right hand hanging down, and the whole body without constraint. The musquets when shouldered, should be exactly dressed in rank and file; the men must keep their bodies upright, and in full front, not having one shoulder too forward, or the other too backward. The distances between the files must be equal, and not greater than from arm to arm, which gives the requisite room for the motions. The ranks are to be two paces distant from each other. Every motion must be done with life, and all facings, wheelings, and marchings, performed with the greatest exactness. Hence a regiment should never be under arms longer than two hours.

Exercise *of the cavalry*, is of two sorts, on horseback and on foot. The squadrons for exercise are sometimes drawn up three deep, though frequently two deep; the tallest men and horses in the front, and so on. When a regiment is formed in squadrons, the distance of 24 feet, as a common interval, is always to be left between the ranks, and the files must keep boot-top to boot-top. The officers commanding squadrons must, above all things, be careful to form with great celerity, and during the whole time of exercise to preserve their several distances. In all wheelings, the flank which wheels must come about in full gallop. The men must keep a steady seat upon their horses, and have their stirrups at a fit length.

Exercise *of the artillery*, is the method of teaching the regiments of artillery the use and practice of all the various machines of war, viz.

Exercise *of the light field-pieces* teaches the men to load, ram, and sponge the guns well; to elevate them according to the distance, by quadrant and screw; to judge of distances and elevations without the quadrant; how to use the portfire, match, and tubes for quick firing; how to fix the drag-ropes, and use them in advancing, retreating, and wheeling with the field-pieces; how to fix and unfix the trail of the carriage on the limbers, and how to fix and unfix the boxes for grape-shot on the carriages of each peice.

Exercise *of the garrison and battering artillery*, is to teach the men how to load, ram, and sponge; how to handle the hand-spikes in elevating and depressing the metal to given distances, and for ricochet; how to adjust the coins, and work the gun to its proper place; and how to point and fire with exactness, &c.

Exercise *for the mortar*, is of two different sorts, viz. with powder and shells unloaded, and with powder and shells loaded; each of which is to teach the men their duty, and to make them handy in using the implements for loading, pointing, traversing, and firing, &c.

Exercise *of the howitzer*, differs but little from the mortar, except that it is liable to various elevations; whereas that of the mortar is fixed to an angle of 45°; but the men should be taught the method of ricochet-firing, and how to practise with grape-shot; each method requiring a particular degree of elevation.

Exercises are also understood of what young gentlemen or cadets learn in the military academies and riding-schools; such as fencing, dancing, riding, the manual exercise, &c. The late establishment at High Wycomb is calculated to render young officers perfectly competent to all the duties of military service, provided they have been previously instructed in the first rudiments. Officers are there taught and exercised in the higher branches of tactics and manœuvres.

EX GRAVI QUERELA, in law, is a writ that lies for the person to whom any lands or tenements in fee are devised by will, and the heir of the devisor enters thereon, and detains them from the devisee. Also where a person devises such lands to another in tail with the remainder over in fee; here if the tenant in tail enters, and is seized by force of the intail, and afterwards he dies without issue, the person in remainder, or reversion, may bring this writ to execute the devise.

EXHALATION, a general term for all effluvia or steams, whether moist or dry, raised from the surface of the earth, in form of vapour. In the strict sense of the word, it applies to dry particles in opposition to Evaporation, which see.

Some indeed distinguish exhalations from vapours; expressing by the former all steams emitted from solid bodies, as earth, fire, sulphur, salts, minerals, &c. and by the latter, the steams raised from water and other

fluids. Exhalations, therefore, according to them, are dry, subtile corpuscles, or effluvia, which are loosened and freed from hard earthy bodies, either by the heat of the sun, the agitation of the air, or the like causes; and being blended in the atmosphere with the moist vapours, help to constitute or form clouds and meteors. See METEOROLOGY.

EXHAUSTIONS, or *the method of Exhaustions*, a method of demonstration founded upon a kind of exhausting a quantity, by continually taking away certain parts of it.

The method of exhaustions was of frequent use among the ancient mathematicians, as Euclid, Archimedes, &c. It is founded on what Euclid says in the 10th book of his Elements, viz. that those quantities are equal whose difference is less than any assignable quantity. Or thus: two quantities, A and B, are equal, when, if to or from one of them, as A, any other quantity, as d, be subtracted, however small it be, then the sum or difference is respectively greater or less than the other quantity B, viz. d being an indefinitely small quantity,

if $A + d$ be greater than B,
and $A - d$ less than B,
then is A equal to B.

This principle is used in the 1st prop. of the 10th book, which imports, that if from the greater of two quantities be taken more than its half, and from the remainder more than its half, and so on, there will at length remain a quantity less than either of those proposed. On this foundation it is demonstrated, that if a regular polygon of an infinite number of sides be inscribed in a circle, or circumscribed about it; then the space, which is the difference between the circle and the polygon, will by degrees be quite exhausted, and the circle become ultimately equal to the polygon. And in this way it is that Archimedes demonstrates that a circle is equal to a right-angled triangle, whose two sides about the right angle are equal, the one to the semidiameter, and the other to the perimeter of the circle.

Upon the method of exhaustions depends the method of indivisibles introduced by Cavalerius, which is but a shorter way of expressing the method of exhaustions: as also Wallis's Arithmetic of Infinites, which is a farther improvement of the method of indivisibles; and hence also the methods of increments, differentials, fluxions and infinite series.

EXHEREDATION, in the civil law, the exclusion of a son by the father from inheriting his estate, termed among us disinheriting.

EXHIBIT, in law, is where a deed, or other writing, being produced in a chancery suit, to be proved by witnesses, the examiner or commissioner appointed after the examination of any such, certifies on the back of the deed, or writing, that the same was shown to the witness, at the time of his examination, and by him sworn to.

EXHUMATION, the digging up of a body interred in holy ground, by the authority of a judge. By the French law the exhumation of a dead body is ordered, upon proof that he was killed in a duel; and a parson may demand the exhumation of any of his parishioners, when interred out of the parish without his consent.

EXIGENT, in law, a writ which lies where the defendant in a personal action cannot be found, nor any effects of his within the county, by which he may be attached or distrained. This writ is directed to the sheriff, to proclaim and call the defendant five county-court days, one day after another, charging him to appear under the pain of outlawry. Where a person indicted of felony, &c. absents himself so long, that the writ of exigent is awarded against him, such a withdrawing will be deemed a flight in law, whereby he is liable to forfeit his goods; and though he afterwards renders himself on the exigent, and is found not guilty, it is said the forfeiture shall stand; but if the party was in prison, or beyond the seas, he, or his executors, may reverse the award of the exigent, by writ of error. Upon all exigents a proclamation shall be issued out to make proclamation in the county where the defendant dwells, for him to yield himself, &c.

EXIGENTERS, four officers in the court of common-pleas, who make all exigents and proclamations, in all actions where process of outlawry lies. Writs of supersedeas, as well as the prothonotaries upon exigents, were likewise drawn up in their office.

EXILIUM, in law, signifies a spoiling, but seems to be restrained to the injury done to tenants by altering their tenure, ejecting them, &c.

EXIT, in law, properly signifies issue or offspring; but is also applied to issues, annual rents, and profits of lands.

EX MERO MOTU, a formula used in the king's charters and letters patent, signifying that he grants them of his own will and motion. It is intended to bar all exceptions that might be taken to the charter or patent, by alleging the king, in granting them, was abused by false suggestions.

EXOACANTHA, a genus of the class and order pentandria digynia. The involucrum is spiny. The flowers all hermaphrodite, with equal inflexions; seeds ovate, striated. There is one species, of no note.

EXOCOETUS, or the *flying-fish*, in ichthyology, a genus belonging to the order of abdominales. See Plate LV. Nat. Hist. fig. 190. The head is scaly, and it has no teeth; it has 10 radii in the branchiostege membrane; the body is whitish, and the belly is angular; the pectoral fins, the instruments of flight, are very large. When pursued by any other fish, it raises itself from the water by means of these long fins, and flies in the air to a considerable distance, till the fins dry, and then it falls down into the water. It is a fish that seems to lead a most miserable life. In its own element it is perpetually harassed by the dorados and other fish of prey. If it endeavours to avoid them by having recourse to the air, it either meets its fate from the gulls or the albatross, or is forced down again into the mouths of the inhabitants of the water, who below keep pace with its aerial excursions. This fish is caught in the Mediterranean and some other seas. It is most common between the tropics, and there its enemies are more particularly numerous. In these climates the flying-fishes spring out of the water by hundreds, to escape the rapacity of the dolphins, sharks, &c. When in the air, they have many formidable enemies to encoun-

ter within that element, viz. the pelican, eagle, diomeda, &c. and frequently throw themselves on board the ships to escape their pursuit. Their flesh is said to supply a palatable and nourishing food. There are two species.

EX OFFICIO, among lawyers, signifies the power a person has, by virtue of his office, to do certain acts without being applied to. Thus a justice of peace may ex officio at his discretion, take surety of the peace, without complaint made by any person whatsoever. There was formerly an oath ex officio, whereby a supposed offender was compelled in the ecclesiastical court to confess, accuse, or clear himself of a crime; but this law is repealed.

EXOMPHALUS, in surgery, called also omphalocele, and hernia umbilicalis, is a preternatural tumor of the abdomen at the navel from a rupture, or distention of the parts which invest that cavity. See SURGERY.

EXORCISM, among the ecclesiastical writers, the expelling devils from persons possessed, by means of conjurations and prayers.

EXORCISTS, in church history, an order of men, in the ancient church, whose employment it was to exorcise or cast out devils. See the preceding article.

EXORDIUM, in rhetoric, is the preamble or beginning, serving to prepare the audience for the rest of the discourse.

EXOTIC, an appellation denoting a thing to be the produce of foreign countries. Exotic plants of the hot climates are very numerous, and require the utmost attention of the gardener to make them thrive with us.

EXPANSION, as generally employed in science, denotes an increase of the bulk of any body by a power acting from within.

It may be laid down as a general rule, to which there is no known exception, that every addition or abstraction of caloric makes a corresponding change in the bulk of the body which has been subjected to this alteration in the quantity of its heat. In general the addition of heat increases the bulk of a body, and the abstraction of it diminishes its bulk; but this is not uniformly the case, though the exceptions are not numerous. Indeed these exceptions are not only confined to a very small number of bodies, but even in them they do not hold, except at certain particular temperatures, while at all other temperatures these bodies are increased in bulk when heated, and diminished in bulk by being cooled. We may therefore consider expansion as one of the most general effects of heat. It is certainly one of the most important, as it has furnished us with the means of measuring all the others.

Though all bodies are expanded by heat and contracted by cold, and this expansion in the same body is always proportional to some function of the quantity of caloric added or subtracted; yet the absolute expansion, or contraction, has been found to differ exceedingly in different bodies. In general, the expansion of gaseous bodies is greatest of all; that of liquids is much smaller, and that of solids the smallest of all. Thus, 100 cubic inches of atmospheric air, by being heated from the temperature of 32° to that of 212°, are increased to 137.5 cubic inches; while the same augmentation of temperature only makes 100 cubic inches of water assume the bulk of 104.5 cubic inches; and 100 cubic inches of iron, when heated from 32° to 212°, assume a bulk scarcely exceeding 100.1 cubic inches. From this example, we see that the expansion of air is more than eight times greater than that of water, and the expansion of water about 45 times greater than that of iron.

An accurate knowledge of the expansion of gaseous bodies being frequently of great importance in chemical researches, many experiments have been made to ascertain it; yet. till lately, the problem was unsolved. The results of philosophers were so various and discordant, that it was impossible to form any opinion on the subject. This was owing to the want of sufficient care in excluding water from the vessels in which the expansion of the gases was measured. The heat which was applied converted portions of this water into vapour, which, mixing with the gas, totally disguised the real changes in bulk which it had undergone. To this circumstance we are to ascribe the difference in the determinations of de Luc, general Roy, Saussure, d'Ivernois, &c. Fortunately the problem has lately engaged the attention of Mr. Dalton of Manchester, and M. Gay Lussac; and their experiments, made with the proper precautions, have solved the problem. Mr. Dalton's experiments are distinguished by a simplicity of apparatus which adds greatly to their value, as it puts it in the power of others to repeat them without difficulty. It consists merely of a glass tube, open at one end, and divided into equal parts; the gas to be examined was introduced into it after being properly dried, and the tube is filled with mercury at the open end to a given point; heat is then applied, and the dilatation is observed by the quantity of mercury which is pushed out. M. Gay Lussac's apparatus is more complicated, but equally precise; and as his experiments were made on larger bulks of air, the coincidence with those of Mr. Dalton adds considerably to the confidence which may be placed in the results.

From the experiments of these philosophers it follows, that all gaseous bodies whatever undergo the same expansion by the same addition of heat, supposing them placed in the same circumstances. It is sufficient then to ascertain the law of expansion observed by any one gaseous body, in order to know the exact rate of dilatation of them all. Now, from the experiments of Gay Lussac we learn, that air, by being heated from 32° to 212°, expands from 100 to 137.5 parts; the increase of bulk for 180° is then 37.5 parts; or, supposing the bulk at 32° to be unity, the increase is equal to 0.375 parts; this gives us 0.00208, or $\frac{1}{480}$th part, for the expansion of air for 1° of the thermometer. Mr. Dalton found, that 100 parts of air, by being heated from 55° to 212°, expanded to 132.5 parts; this gives us an expansion of 0.00207, or $\frac{1}{483}$ part, for 1°; which differs as little from the determination of Lussac as can be expected in experiments of such delicacy.

From the experiments of Mr. Dalton, it appears that the expansion of air is almost perfectly equable; that is to say, that the same increase of bulk takes place by the same addition of caloric at all different temperatures. It is true, indeed, that the rate of diminution appears to diminish as the temperature increases. Thus the expansion from 55° to 133$\frac{1}{2}$°, or for the first 77$\frac{1}{2}$ degrees, was 167 parts; while the expansion from 133$\frac{1}{2}$ to 212°, or for the next 77$\frac{1}{2}$°, was only 158 parts, or 9 parts less than

the first. But this difference, in all likelihood, is chiefly apparent; for de Luc has demonstrated that the thermometer is not an accurate measure of the increase of heat.

From the experiments of Gay Lussac, it appears that the steam of water, and the vapour of ether, undergo the same dilatation with air when the same addition is made to their temperature. We may conclude then that all elastic fluids expand equally and uniformly by heat; and that this expansion is nearly equable, though not perfectly so. The following table gives us the bulk of a given quantity of air at all temperatures from 32° to 212°.

Tem.	Bulk.	Tem.	Bulk.	Tem.	Bulk.
32°	100000	59°	105616	86°	111232

57	105220	84	110816	210	137024
58	105408	85	111024	212	137440

The expansion of liquid bodies differs from that of the elastic fluids, not only in quantity, but in the want of uniformity with which they expand when equal additions are made to the temperature of each. This difference seems to depend upon the fixity or volatility of the component parts of the liquid bodies; for in general those liquids expand most by a given addition of heat, whose boiling temperatures are lowest, or which contain in them an ingredient which readily assumes the gaseous form. Thus mercury expands less when heated to a given temperature than water, which boils at a heat much inferior to mercury; and alcohol is much more expanded than water, because its boiling temperature is lower. In like manner nitric acid is much more expanded than sulphuric acid; not only because its boiling point is lower, but because a portion of it has a tendency to assume the form of an elastic fluid. We may consider it therefore as a pretty general fact, that the higher the temperature necessary to cause a liquid to boil, the smaller is the expansion which is produced by the addition of a degree of heat; or, in other words, the expansibility of liquids is nearly inversely as their boiling temperature.

Another circumstance respecting the expansion of liquids deserves particular attention. The expansibility of every one seems to increase with the temperature; or, in other words, the nearer a liquid is to the temperature at which it boils, the greater is the expansion produced by the addition of a degree of caloric; and, on the other hand, the farther it is from the boiling temperature, the smaller is the increase of bulk produced by the addition of a degree of caloric. Hence it happens, that the expansion of those liquids approaches nearest to equability whose boiling temperatures are highest; or, to speak more precisely, the ratio of the expansibility increases the more slowly, the higher the boiling temperature.

These observations are sufficient to show, that the expansion of liquids is altogether unconnected with their density. It depends upon the quantity of heat necessary to cause them to boil, and to convert them into elastic fluids. But we are altogether ignorant at present of the reason why different liquids require different temperatures to produce this change.

The following table will give the reader a precise notion of the rate of expansion of those liquids which have been hitherto examined by chemical philosophers.

Temp.	Mercury.	Linseed oil.	Sulphuric acid.	Nitric acid.	Water.	Oil of turpentine.	Alcohol.

The expansion of solid bodies is so small, that a micrometer is necessary to detect the increase of bulk. As far as is known, the expansion is equable, at least the deviation from perfect equality is insensible. The following table exhibits the expansion of most of the solids which have been hitherto examined. Most of the experiments were made by Smeaton.

Temp.	Platinum.	Antimony.	Steel.	Iron.	Cast-Iron.	Bismuth.
32°	120000	120000	120000	120000	120000	120000
212	120104	120130	120147	120151		120167
White-heat			123428	121500	122571	

Temp.	Copper.	Cast Brass.	Brass wire.	Tin.	Lead.	Zinc.
32°	120000	120000	120000	120000	120000	120000
212	120204	120225	120232	120298	120344	120355

Temp.	Hammered zinc.	Zinc 8. Tin 1.	Lead 2. Tin 1.	Brass 2. Zinc 1.	Pewter.	Copper 3. Tin 1.
32°	120000	120000	120000	120000	120000	120000
212	120373	120323	120301	120247	120274	120218

The expansion of glass is a point of great importance, as it influences the result of most experiments on temperature. It has been examined with much precision by M. de Luc. The rate of its expansion, as settled by that philosopher, may be seen in the following table:

Temp.	Bulk.	Temp.	Bulk.	Temp.	Bulk.
32°	100000	100°	100023	167°	100056
50	100006	120	100033	190	100069
70	100014	150	100044	212	100083

From this table it appears, that when glass is heated one degree, it undergoes an expansion which amounts nearly to $\frac{1}{200000}$ of the whole bulk.

On the supposition that metals expand equably, the expansion of a mass of metal, by being heated a given number of degrees, is as follows: Let a = the expansion of the mass in length for 1°, which must be found by experiment; b = the number of degrees whose expansion is required; s = the solid contents of the metallic mass; x = the expansion sought; then $x = 3\,b\,a\,s$.

The property which bodies possess of expanding when heat is applied to them, has furnished us with an instrument for measuring the relative temperature of bodies. See THERMOMETER.

Having considered the phenomena and laws of expansion as far as they are understood, it will be proper to state the exceptions to this general effect of heat, or the cases in which expansion is produced not by an increase, but by a diminution of temperature. These exceptions may be divided into two classes. The first class comprehends certain liquid bodies which have a maximum of density corresponding with a certain temperature; and which, if they are heated above that temperature, or cooled down below it, undergo in both cases an expansion or increase of bulk. The second class comprehends certain liquids which suddenly become solid when cooled down to a certain temperature; and this solidification is accompanied by an increase of bulk.

Water furnishes us with the most remarkable example of the first class of bodies. Its maximum of density corresponds with 42.5° of Fahrenheit's thermometer, as has been lately ascertained by Mr. Dalton. If it is cooled down below 42.5°, it undergoes an expansion for every degree of temperature which it loses; and 32° the expansion amounts, according to Mr. Dalton, to $\frac{1}{160}$ of the whole expansion which water undergoes when heated from 42.5° to 212°. With this more recent experiments coincide very nearly; for by cooling 100000 parts in bulk of water from 42.5° to 32°, they were converted to 100031 parts. We are indebted to the ingenuity of Mr. Dalton for the discovery of a very unexpected fact, that the expansion of water is the same for any number of degrees above or below the maximum of density. Thus if we heat water ten degrees above 42.5°, it occupies precisely the same bulk as it does when cooled down ten degrees below 42.5°. Therefore the density of water at 32° and at 53° is precisely the same. Mr. Dalton succeeded in cooling water down to the temperature of 5° without freezing, or 37.5° below the maximum point of density; and during the whole of that range, its bulk precisely corresponds with the bulk of water the same number of degrees above 42.5°. Thus the bulk of water at 5° is the same as the bulk of water at 80°. The scale of expansion, therefore, which has been given for the expansion of water when heated, answers also for its expansion when cooled, provided the table begin at 42.5°, as is done in the table of the expansion of water. From this table it appears that the expansion of water, the original bulk being 10000, may be expressed pretty nearly by the following numbers:

Temp.		Expan.
82.5°	.	6^2
102.5°	.	8^2
122.5°	.	10^2
142.5°	.	12^2
162.5°	.	14^2

The greatest deviation from these numbers is towards the beginning of the scale, when, owing to the smallness of the expansion, it is difficult to measure it with precision. It leads us to this remarkable conclusion, that the squares of the natural numbers beginning at 6 indicate the increase of bulk which 10000 parts of water experience for every ten degrees they are heated

happen; the probability that a life of 30 will not live 10 years, is therefore $\frac{750}{4335}$, consequently the odds of living to dying in this period, are nearly 5 to 1. The probability that a person of 21 shall attain to 51, appears by the table to be $\frac{2530}{5060}$, or an even chance.

TABLE II.

Showing the Expectation of Human Life at every Age, according to the Probabilities in the preceding Table.

Age.	Expectation.	Age.	Expectation.	Age.	Expectation.
0	25,18	33	26,72	66	10,42
1	32 74	34	26,20	67	9,96

28	29,30	61	12,75	94	1,05
29	28,79	62	12,28	95	0,75
30	28,27	63	11,81	96	0,50
31	27,76	64	11,35		
32	27,24	65	10,88		

These tables are, for general use, the best that have been formed; but it is well known, that the duration of human life is much influenced by different situations; that it is greater in mountainous countries than in marshy districts; and that the country in general is much more favourable to the continuance of life than large towns. In proof of the latter assertion Dr. Price has observed, that in London the greater part of the natives die under three years of age, while in the country the greater part live to marry. The observations of Mr. Muret on the state of population in the Pays de Vaud, a district of the province of Bern in Switzerland, also confirm this remark, by showing that the greater part of the inhabitants of that province live many years beyound maturity. A comparison of the expectations of life will exhibit this difference in a striking point of view.

These comparisons strongly show the baleful influence of great cities, in shortening human life. The irregular modes of life, the luxuries, debaucheries, and pernicious customs, which prevail much more in towns than in the country; and the foulness of the air, which is rendered in a great degree unfit for respiration; are undoubtedly the causes which produce this fatal effect.

EXPECTORANTS. See Pharmacy.

EXPECTORATION, the act of evacuating or bringing up phlegm, or other matters, out of the trachea and lungs, by coughing, &c.

EXPENDITORS, the persons who disburse or expend the money collected by the tax for repairs of sewers, after the same is paid into their hands by the collectors, as ordered by the commissioners, and for which they are to render accounts when required.

EXPENSIS MILITUM LEVANDIS, a writ anciently directed to the sheriff for levying the allowance for knights of the shire; and expensis militum non levandis, was a writ to hinder the sheriff from levying such allowance upon lands that held in ancient demesne.

EXPERIMENTAL PHILOSOPHY, that philosophy which proceeds on experiments; which deduces the laws of nature, and the properties and powers of bodies, and their actions upon each other, from sensible experiments and observations. The business of experimental philosophy is to inquire into and to investigate the reasons and causes of the various appearances or phænomena of nature; and to make the truth or probability of them obvious and evident to the senses, by plain, undeniable, and adequate experiments, representing the several parts of the grand machinery and agency of nature.

In our inquiries into nature, we are to be conducted by those rules and maxims which are found to be genuine, and consonant to a just method of physical reasoning; and these rules of philosophizing are by the greatest master in science, sir Isaac Newton, reckoned four, which are as follows:

1. More causes of natural things are not to be admitted, than are both true, and sufficient to explain the phænomena: for nature does nothing in vain, but is simple, and delights not in superfluous causes of things.

2. And, therefore, of natural effects of the same kind, the same causes are to be assigned, as far as it can be done; as of respiration in man and beasts, of the descent of stones in Europe and America, of light in a culinary fire and in the sun, and of the reflection of light in the earth and in the planets.

3. The qualities of natural bodies which cannot be increased or diminished, and agree to all bodies on which experiments can be made, are to be reckoned as the qualities of all bodies whatever; thus, because extension, divisibility, hardness, impenetrability, mobility, the vis inertiæ, and gravity, are found in all bodies which fall under our cognizance or inspection, we may justly conclude they belong to all bodies whatever, and are therefore to be esteemed the original and universal properties of all natural bodies.

4. In experimental philosophy, propositions collected from the phænomena by induction, are to be deemed (notwithstanding contrary hypotheses) either exactly or very nearly true, till other phænomena occur, by which they may be rendered either more accurate, or liable to exception. This ought to be done, lest arguments of induction should be destroyed by hypotheses.

These four rules of philosophizing are premised by sir Isaac Newton to his third book of the Principia; and more particularly explained by him in his Optics, where he exhibits the method of proceeding in philosophy, the first part of which is as follows:

As in mathematics, so in natural history, the investigation of difficult things, by way of analysis, ought always to precede the method of composition. This analysis consists in making experiments and observations, and in drawing general conclusions from them by induction (*i. e.* reasoning from the analogy of things by natural consequence); and admitting no objections against the conclusions, but what are taken from experiments or certain truths. And although the reasoning from experiments and observations, by induction, is no demonstration of general conclusions, yet it is the best mode of reasoning which the nature of things admits of, and may be looked on as so much the stronger, by how much the induction is more general; and if no exception occurs from phænomena, the conclusion may be pronounced generally; but if at any time afterwards, any exception shall occur from experiments, it may then be pronounced with such exceptions; by this way of analysis we may proceed from compounds to ingredients, and from motions to the causes producing them; and in general from effects to their causes, and from particular causes to more general ones, till the argument ends in the most general; this is the method of analysis. And that of synthesis, or composition, consists in assuming causes, discovered and established as principles, and by them explaining the phænomena proceeding from them, and proving the explanations. Though the whole history of nature is open to the researches of experimental philosophy, yet its principal branches may be accounted, attraction, gravitation, the laws of matter and motion, magnetism, optics, electricity, pneumatics, hydrostatics, hydraulics, and mechanics.

EXPERIMENTUM CRUCIS, a leading, or decisive experiment; thus termed, either on account of its being like a cross, or direction post, placed in the meeting of several roads, guiding men to the true knowledge of the nature of that thing they are inquiring after; or, on account of its being a kind of torture, whereby the nature of the thing is in a manner extorted by force.

EXPIATION, *great day of*, an annual solemnity of the Jews, upon the tenth day of the month Tisri, which answers to our September. On this occasion the high priest laid aside his breatplate and embroidered ephod,

above 82.5°, or cooled below 12.5°. This rule will give the reader a more precise idea of the rate at which water expands, when heated or cooled, than a bare inspection of the table could do.

A considerable number of liquids has been tried to ascertain whether any of them, like water, have a temperature in which their density is a maximum, and which expand when cooled below that temperature. Sulphuric acid has no such point, neither have the oily bodies; but some solutions of salt in water begin to expand before they become solid. These solutions, however, when cooled down sufficiently, crystallize with such rapidity, that it is extremely difficult to be certain of the fact, that they really do begin to expand before they crystallize.

That class of bodies which undergo an expansion when they change from a liquid to a solid body by the diminution of temperature, is very numerous. Not only water when converted into ice undergoes such an expansion, but all bodies which by cooling assume the form of crystals.

The prodigious force with which water expands in the act of freezing has been long known to philosophers. Glass bottles filled with water are commonly broken in pieces when the water freezes. The Florentine academicians burst a brass globe whose cavity was an inch in diameter, by filling it with water and freezing it. The force necessary for this effect was calculated by Muschenbroeck at 27720 lbs. But the most complete set of experiments on the expansive force of freezing water are those made by major Williams at Quebec, and published in the second volume of the Edinburgh Transactions. This expansion has been explained, by supposing it the consequence of a tendency which water, in consolidating, is observed to have to arrange its particles in one determinate manner, so as to form prismatic crystals, crossing each other at angles of 60° and 120°. The force with which they arrange themselves in this manner must be enormous, since it enables small quantities of water to overcome so great mechanical pressures. Various methods have been tried to ascertain the specific gravity of ice at 32°; that which succeeded best was to dilute spirits of wine with water till a mass of solid ice put into it remained in any part of the liquid without either sinking or rising. The specific gravity of such a liquid is 0.92, which of course is the specific gravity of ice, supposing the specific gravity of water at 60° to be 1. This is an expansion much greater than water experiences even when heated to 212°. We see from this, that water, when converted into ice, no longer observes that equable expansion measured by Mr. Dalton, but undergoes a very rapid and considerable augmentation of bulk.

The very same expansion is observed during the crystallization of most of the salts; all of them at least which shoot into prismatic forms. Hence the reason that the glass vessels in which such liquids are left, usually break to pieces when the crystals are formed.

This expansion of these bodies cannot be considered as an exception to the general fact, that bodies increase in bulk when heat is added to them, for the expansion is the consequence, not of the diminution of heat, but of the change in their state from liquids to solids, and the new arrangment of their particles which accompanies or constitutes that change.

It must be observed, however, that all bodies do not expand when they become solid. There are a considerable number which diminish in bulk; and in these the rate of diminution in most cases is rather increased by solidification. When liquid bodies are converted into solids, they either form prismatic crystals, or they form a mass in which no regularity of arrangement can be perceived. In the first case, expansion accompanies solidification; in the second place, contraction accompanies it. Water and all the salts furnish instances of the first, and tallow and oils are examples of the second. In these last bodies the solidification does not take place instantaneously, as in water and salts, but slowly and gradually; they first become viscid, and at last quite solid. Most of the oils, when they solidify, form very regular spheres. The same thing happens to honey, and to some metals. It has been thought that all combustible liquids contract, when they become solid, while incombustible liquids expand; but there are exceptions to this rule. Sulphuric acid does not by congelation alter its appearance; but cast iron, and perhaps sulphur also, expand in the act of congealing.

EX PARTE, a term used in the court of chancery, when a commission is taken out and executed by one side or party only, upon the other parties neglecting or refusing to join therein. When both the parties proceed together, it is called a joint commission.

Ex parte talis, a writ that lies for a bailiff or receiver, that having auditors assigned to pass his accounts, cannot procure from them reasonable allowance, but is cast into prison; in which case the practice is to sue this writ out of the chancery, directed to the sheriff to take the four mainpernors to bring his body before the barons of the exchequer, at a certain day, and to warn the lord to appear at the same time.

EXPECTANT, in law, signifies having relation to, or depending on; thus, where land is given to a man and his wife, and to their heirs, they have a fee simple estate; but if it be given to them and the heirs of their bodies begotten, they have an estate tail, and a fee expectant, which is opposed to fee simple.

EXPECTATION, in the doctrine of chances, is applied to any contingent event, upon the happening of which some benefit, &c. is expected. This is capable of being reduced to the rules of computation; for a sum of money in expectation when a particular event happens, has a determinative value before that event happens. Thus, if a person is to receive any sum as 10*l.* when an event takes place which has an equal chance or probability of happening and failing, the value of the expectation is half that sum, or 5*l.*; but if there are three chances for failing, and only one for its happening, or one chance only in its favour out of all the four chances, then the probability of its happening is only one out of four, or $\frac{1}{4}$, and the value of the expectation is but $\frac{1}{4}$ of 10*l.* which is only 2*l.* 10*s.* or half the former sum. And in all cases, the value of the expectation of any sum is found by multiplying that sum by the fraction expressing

the probability of obtaining it. So the value of the expectation on 100*l.* when there are three chances out of five for obtaining it, or when the probability of obtaining it is 3-fifths, is 3-fifths of 100*l.* which is 60*l.* And if s be any sum expected on the happening of an event, h the chances for that event happening, and f the chances for its failing: then, there being h chances out of $f + h$ for its happening, the probability will be $\frac{h}{f + h}$, and the value of the expectation is $\frac{h}{f + h} \times s$. See CHANCES.

EXPECTATION *of Life*, the share of life due to a person of a given age, according to a table of mortality. The most obvious sense of the term, is certainly, "the particular number of years which a life of a given age has an equal chance of enjoying:" this is the time that a person may reasonably expect to live; for the chances against his living longer are greater than those for it; and therefore, he cannot entertain an expectation of living longer, consistently with probability; but this period does not coincide with what the writers on Life Annuities call the Expectation of Life, except on the supposition of an uniform decrease in the probabilities of life, as Mr. Simpson has observed in his Select Exercises; and Dr. Price adds, that even on this supposition, it does not coincide with what is called the expectation of life, in any case of joint lives; he therefore defines it more accurately to be, "The mean continuance of any given single, joint, or surviving lives, according to any given table of observations:" that is, the number of years which, taking them one with another, they actually enjoy, and may be considered as sure of enjoying; those who live or survive beyond that period, enjoying as much more time in proportion to their number, as those who fall short of it enjoy less.

The particular proportion that becomes extinct every year, out of the whole number constantly existing together of single or joint lives, must, whenever this number undergoes no variation, be the same with the expectation of those lives, at the time when their existence commenced. Thus, was it found in any town or district, where the number of births and burials are equal, that a 20th or a 30th part of the inhabitants die annually, it would appear, that 20 or 30 was the expectation of a child just born in that town or district; and if a 13th part of all the inhabitants of the age of 60 years and upwards die annually, the expectation of a person of 60 years of age is 13 years. These expectations, therefore, for all single lives, are easily found by a Table of Mortality, showing the number that die annually at all ages, out of a given number alive at those ages; and the general rule for this purpose is, "to divide the sum of all the living in the table, at the age whose expectation is required, and at all greater ages, by the sum of all that die annually at that age, and above it; or, which is the same, by the number in the table of the living at that age: and half unity subtracted from the quotient will be the required expectation. Thus the sum of all the living at the age of 60 and upwards, in Table I, is 27965, which divided by 2038, the number living at that age, and the quotient less half unity, gives 13.21, the expectation of 60, as in table II.

TABLE I.

Showing the Probabilities of the Duration of Human Life, deduced from the Register of Mortality at Northampton.

48	3014	78			

The probability that a given life shall continue any number of years, or reach a given age, is the fraction, whose numerator is the number of living in the table opposite to the given age; and denominator, the number opposite to the present age of the given life. Thus, the probability that a life of 30 shall attain to 40, or live 10 years, is $\frac{3635}{4385}$. The difference between this fraction and unity gives the probability that the event will *not*

happen; the probability that a life of 30 will not live 10 years, is therefore $\frac{750}{4335}$, consequently the odds of living to dying in this period, are nearly 5 to 1. The probability that a person of 21 shall attain to 51, appears by the table to be $\frac{2530}{5060}$, or an even chance.

TABLE II.

Showing the Expectation of Human Life at every Age, according to the Probabilities in the preceding Table.

Age.	Expectation.	Age.	Expectation.	Age.	Expectation.

32	27,24	65	10,88		

These tables are, for general use, the best that have been formed; but it is well known, that the duration of human life is much influenced by different situations; that it is greater in mountainous countries than in marshy districts; and that the country in general is much more favourable to the continuance of life than large towns. In proof of the latter assertion Dr. Price has observed, that in London the greater part of the natives die under three years of age, while in the country the greater part live to marry. The observations of Mr. Muret on the state of population in the Pays de Vaud, a district of the province of Bern in Switzerland, also confirm this remark, by showing that the greater part of the inhabitants of that province live many years beyound maturity. A comparison of the expectations of life will exhibit this difference in a striking point of view.

These comparisons strongly show the baleful influence of great cities, in shortening human life. The irregular modes of life, the luxuries, debaucheries, and pernicious customs, which prevail much more in towns than in the country; and the foulness of the air, which is rendered in a great degree unfit for respiration; are undoubtedly the causes which produce this fatal effect.

EXPECTORANTS. See Pharmacy.

EXPECTORATION, the act of evacuating or bringing up phlegm, or other matters, out of the trachea and lungs, by coughing, &c.

EXPENDITORS, the persons who disburse or expend the money collected by the tax for repairs of sewers, after the same is paid into their hands by the collectors, as ordered by the commissioners, and for which they are to render accounts when required.

EXPENSIS MILITUM LEVANDIS, a writ anciently directed to the sheriff for levying the allowance for knights of the shire; and expensis militum non levandis, was a writ to hinder the sheriff from levying such allowance upon lands that held in ancient demense.

EXPERIMENTAL PHILOSOPHY, that philosophy which proceeds on experiments; which deduces the laws of nature, and the properties and powers of bodies, and their actions upon each other, from sensible experiments and observations. The business of experimental philosophy is to inquire into and to investigate the reasons and causes of the various appearances or phænomena of nature; and to make the truth or probability of them obvious and evident to the senses, by plain, undeniable, and adequate experiments, representing the several parts of the grand machinery and agency of nature.

In our inquiries into nature, we are to be conducted by those rules and maxims which are found to be genuine, and consonant to a just method of physical reasoning; and these rules of philosophizing are by the greatest master in science, sir Isaac Newton, reckoned four, which are as follows:

1. More causes of natural things are not to be admitted, than are both true, and sufficient to explain the phænomena: for nature does nothing in vain, but is simple, and delights not in superfluous causes of things.

2. And, therefore, of natural effects of the same kind, the same causes are to be assigned, as far as it can be done; as of respiration in man and beasts, of the descent of stones in Europe and America, of light in a culinary fire and in the sun, and of the reflection of light in the earth and in the planets.

3. The qualities of natural bodies which cannot be increased or diminished, and agree to all bodies on which experiments can be made, are to be reckoned as the qualities of all bodies whatever; thus, because extension, divisibility, hardness, impenetrability, mobility, the vis inertiæ, and gravity, are found in all bodies which fall under our cognizance or inspection, we may justly conclude they belong to all bodies whatever, and are therefore to be esteemed the original and universal properties of all natural bodies.

4. In experimental philosophy, propositions collected from the phænomena by induction, are to be deemed (notwithstanding contrary hypotheses) either exactly or very nearly true, till other phænomena occur, by which they may be rendered either more accurate, or liable to exception. This ought to be done, lest arguments of induction should be destroyed by hypotheses.

These four rules of philosophizing are premised by sir Isaac Newton to his third book of the Principia; and more particularly explained by him in his Optics, where he exhibits the method of proceeding in philosophy, the first part of which is as follows:

As in mathematics, so in natural history, the investigation of difficult things, by way of analysis, ought always to precede the method of composition. This analysis consists in making experiments and observations, and in drawing general conclusions from them by induction (*i. e.* reasoning from the analogy of things by natural consequence); and admitting no objections against the conclusions, but what are taken from experiments or certain truths. And although the reasoning from experiments and observations, by induction, is no demonstration of general conclusions, yet it is the best mode of reasoning which the nature of things admits of, and may be looked on as so much the stronger, by how much the induction is more general; and if no exception occurs from phænomena, the conclusion may be pronounced generally; but if at any time afterwards, any exception shall occur from experiments, it may then be pronounced with such exceptions; by this way of analysis we may proceed from compounds to ingredients, and from motions to the causes producing them; and in general from effects to their causes, and from particular causes to more general ones, till the argument ends in the most general; this is the method of analysis. And that of synthesis, or composition, consists in assuming causes, discovered and established as principles, and by them explaining the phænomena proceeding from them, and proving the explanations. Though the whole history of nature is open to the researches of experimental philosophy, yet its principal branches may be accounted, attraction, gravitation, the laws of matter and motion, magnetism, optics, electricity, pneumatics, hydrostatics, hydraulics, and mechanics.

EXPERIMENTUM CRUCIS, a leading, or decisive experiment; thus termed, either on account of its being like a cross, or direction post, placed in the meeting of several roads, guiding men to the true knowledge of the nature of that thing they are inquiring after; or, on account of its being a kind of torture, whereby the nature of the thing is in a manner extorted by force.

EXPIATION, *great day of*, an annual solemnity of the Jews, upon the tenth day of the month Tisri, which answers to our September. On this occasion the high priest laid aside his breatplate and embroidered ephod,

as being a day of humiliation. He first offered a bullock and a ram for his own sins, and those of the priests; then he received from the heads of the people two goats for a sin-offering, and a ram for a burnt-offering, to be offered in the name of the whole multitude. It was determined by lot which of the goats should be sacrificed, and which set at liberty. After this he perfumed the sanctuary with incense, and sprinkled it with blood; then, coming out, he sacrificed the goat upon which the lot had fallen. This done, the goat which was to be set at liberty, being brought to him, he laid his hands upon its head, confessed his sins and the sins of the people, and then sent him away into some desert place: it was called azazel, or the scape goat.

EXPILATION, among civilians, the carrying off or sequestering something belonging to an inheritance, before the heir had intermeddled with it.

Expilation also denoted a robbery committed by night, and was so called from the robbers stripping people of their clothes.

EXPLOSION, in natural philosophy, a sudden and violent expansion of an aerial or other elastic fluid, by which it instantly throws off any obstacle that happens to be in the way, sometimes with incredible force, and in such a manner as to produce the most astonishing effects upon the neighbouring objects. Explosion differs from expansion, in this: that the latter is a gradual and continued power, acting uniformly for some time; whereas the former is always sudden, and only of a momentary duration. The expansions of solid substances do not terminate in violent explosions, on account of their slowness, and the small space through which the metal, or other expanding substance, moves, though their strength may be equally great with that of the most active aerial fluids. Thus we find, that though wedges of wood, when wetted, will cleave solid blocks of stone, they never throw them to any distance, as is the case with gunpowder. On the other hand, it is seldom that the expansion of any elastic fluid bursts a solid substance, without throwing the fragments of it to a considerable distance, the effects of which are often very terrible. The reasons of this may be comprised in the two following particulars. 1. The immense velocity with which the aerial fluids expand, when affected by a considerable degree of heat. 2. Their celerity in acquiring heat, and being affected by it, which is much superior to that of solid substances. Thus air, heated as much as iron when brought to a white heat, is expanded to four times its bulk; but the metal itself will not be expanded the 500th part of that space. In the case of gunpowder, which is a violent and well-known explosive substance, the velocity with which the flame moves is calculated by Mr. Robins, in his treatise upon Gunnery, to be no less than 7000 feet in a second, or little less than 79 miles per minute. Hence the impulse of the fluid is inconceivably great, and the obstacles on which it strikes are hurried off with vast velocity, though much less than that just mentioned; for a cannon-ball, with the greatest charge of powder that can be conveniently given, does not move at a greater rate than 2400 feet per second, or little more than 27 miles per minute. The velocity of the ball again is promoted by the sudden propagation of the heat through the whole body of the air, as soon as it is extricated from the materials of which the gunpowder is made, so that it is enabled to strike all at once, and thus greatly to augment the momentum of the ball. It is evident that this contributes very much to the force of the explosion, by what happens when powder is wetted or mixed with any substance, which prevents it from taking fire all at once. In this case the force of the explosion, even when the same quantity of powder is made use of, is not to be compared with that of dry powder.

We may conclude, upon these principles, that the force of an explosion depends, 1. on the quantity of elastic fluid to be expanded; 2. on the velocity it acquires by a certain degree of heat; and 3. on the celerity with which the degree of heat affects the whole of the expansile fluid. These three take place in the greatest perfection where the electric fluid is concerned, as in cases of lightning, earthquakes, and volcanoes. This fluid pervades the whole system of nature; its expansion is nothing else than its motion from a centre towards a circumference, for it does not seem capable of any proper expansion by a separation of its parts like any other fluid. Hence, when it begins to expand in this manner, the motion is propagated through it, with a velocity far exceeding that of any other fluid whatever. Thus, even when the quantity is excessively small, as when an electric spark is sent through a glass full of water or of oil, the expansion is so violent as to dissipate the glass into innumerable fragments, with great danger to the by-standers. In violent lightning, when the electric fluid is much concentrated, the strength of the explosion is proportionable to the quantity. Every one has heard of the prodigious effects of lightning when it happens to strike buildings, trees, or even the most solid rocks; and in some cases, where the quantity of electricity is still greater than in any flash of lightning, we hear of still more tremendous consequences ensuing. Dr. Priestley gives an instance of a large fire-ball rolling on the surface of the sea, which, after rising up to the top-mast of a ship of war, burst with such violence, that the explosion resembled the discharge of hundreds of cannons fired at once. Great damage was done by it; but there is not the least doubt that most of its force was spent on the air, or carried down to the sea by the mast and iron-work of the ship. Indeed, considering that in all cases a great part of the force of electric explosions is dissipated in this manner, it may justly be doubted whether they can be measured by any method applicable to the mensuration of other forces. Even in artificial electricity the force is prodigiously great, insomuch that Dr. Van Marum calculated that of the great battery belonging to the machine in Teyler's museum to be upwards of 900 pounds.

Whenever the electrical fluid acts like common fire, the force of the explosions, though exceedingly great, is capable of mensuration, by comparing the distances to which the bodies are thrown with their weight. This is most evident in volcanoes, where the projections of the burning rocks and lava manifest the greatness of the power, at the same time that they afford a method of measuring it. By means of the fire which kindles the volcanoes, the aerial fluids are suddenly restored to their elastic state; and not only so, but their natural elasticity is greatly augmented, so that the explosions take place with great violence. The case is the same with

gunpowder. The reason of the extreme quickness of the explosion of gunpowder, is, that it takes fire so readily by the intimate mixture and combustibility of all the materials. In volcanoes the explosions likewise follow one another very quickly, and are by no means inferior in strength to those of gunpowder; but here the quantity of vapour makes up for the comparative slowness with which it is affected by the heat. Thus, though we could not by any other means contrive to fire cannon in such quick succession as we can do with gunpowder, yet in the huge furnace of a volcano the elastic matter is supplied in such quantities, that the explosions are in a manner unremitting; and even in ordinary experiments the confinement of aerial vapours has often occasioned violent explosions in chemical vessels. Carbonic acid gas though heavier than most of the other aerial fluids, yet by its expansion contributes equally to the force of the explosion, as is evident, in that of pulvis fulminans. This is compounded of sulphur, saltpetre, and salt of tartar. The latter we know contains much carbonic acid gas; and it is probable that the violence of the explosion is occasioned by this air; for it is said that the greater quantity of it the alkaline salt contains, the greater force does it explode with.

Next in strength to the aerial vapours are those of aqueous and other liquids. The most remarkable effects of these are observed in steam-engines; but there is one particular case from which it has been inferred that aqueous steam is vastly stronger than the flame of gunpowder. This is when water is thrown upon melted copper; for here the explosion is so strong as almost to exceed imagination; and the most terrible accidents have been known to happen from such a slight cause as one of the workmen spitting in the furnace where copper was melting. Here, however, it is most probable that a decomposition of the water takes place, and on this supposition, the phænomenon is easily solved. The water being thrown in substance upon the melted copper, is decomposed by the violent heat; and one part of it adheres to the metal, thus converting it into a kind of calx, while the other is converted into inflammable air, which expanding suddenly, throws the melted metal about with the greatest violence by means of its reaction.

In order to understand the manner in which this is accomplished, we must consider some of the principles of gunnery laid down by Mr. Robins. One of these is, that though the air, in case of ordinary velocity, makes no great resistance, it is far otherwise where the velocity of the moving body becomes very great. In all cases of explosion also there is in the first instance a vacuum made by the exploding fluid; and consequently the weight of the atmosphere is to be overcome, which amounts to about 15 pounds on every square inch of surface. Supposing the surface of the exploding fluid then, on that of melted copper, to contain an area of four square inches, it meets with a resistance of 60 pounds from the atmosphere, and consequently communicates an equal pressure to the fluid metal. Even this must of consequence throw it about, unless the same pressure was exactly diffused over every part of the surface. But much more must this effect be increased by the immense velocity with which the fluid moves, and by which the resistance of the atmosphere is augmented in a prodigious degree. The elastic fluid generated is then confined not only by the fluid metal and sides of the furnace, but by the air itself, which cannot get out of the way, so that the whole resembles a cannon closed at the mouth, and filled with inflamed gunpowder. Hence not only the melted metal, but the furnace itself, and the adjacent walls of the building, are hurried off as they would be by the firing of a great quantity of gunpowder in a small space, and which is well known to produce analogous effects.

Dr. Black, in explaining the phænomenon in question, supposes that the mere heat of the metal applied to the aqueous steam produces the explosion; and in proof of this, alleges that copper imbibes a greater quantity of heat during fusion than any other metal. Aqueous steam, however, seems to be too slow for producing such sudden and violent effects. Explosions, it is true, will be occasioned by it, but then it must be confined for a very considerable time, whereas the effects of water thrown upon melted copper are instantaneous.

It must be observed, that in all cases, where a very hot body is thrown upon a small quantity of water in substance, an explosion will follow; but here the water is confined, and suddenly rarefied into steam, which cannot get away without throwing off the body which confines it. Examples of this kind frequently occur where masons, or other mechanics, are employed in fastening cramps of iron into stones; where, if there happens to be a little water in the hole into which the lead is poured, the latter will fly out in such a manner as sometimes to burn them severely. Terrible accidents of this kind have sometimes happened in foundries, when large quantities of melted metal have been poured into wet moulds. In these cases, the sudden expansion of the aqueous steam has thrown out the metal with violence; and if any decomposition has taken place at the same time, so as to convert the aqueous into an aerial vapour, the explosion must be still greater.

To this last kind of explosion we must refer that which takes place on pouring cold water into boiling or burning oil or tallow. Here the case is much the same whether we pour the oil on the water, or the water on the oil. In the former case, the water which lies at the bottom is rarefied into steam, and explodes; in the latter, it sinks down through the oil by its superior specific gravity, and explodes as it passes along. In either case, however, the quantity of aqueous fluid must be but small in proportion to that of the oil; a very great quantity would put out the flame, or destroy the heat, in whatever way we applied it.

Another kind of explosion is that which takes place in solid substances, where we can scarcely suppose either aqueous or aerial vapours to be concerned. The most remarkable of these are the volcanic bombs mentioned by sir William Hamilton in the great eruption of Vesuvius in 1779. They were large pieces of lava, which burst in pieces like bombs as they fell to the ground; but he does not inform us whether their bursting was attended with any great violence or not. Indeed, amidst such scenes of horror, and the continual tremendous explosions of the volcano, smaller phænomena of this kind would probably be overlooked.

The only other kind of explosion we have to take notice of, is that produced by hydrogen and oxygen gases,

The countries to which the above goods were exported were as follows:

	Livres.
To Spain	62,441,400
Batavian republic	37,751,600
Ligucian republic	23,010,700
Helvetian republic	38,809,100
Denmark, Sweden, Prussia, and the Hans towns	32,969,700
The United States of America	557,700
The Levant, Sardinia, Italy, Portugal, Germany, and other states then at war with France	76,035,400
Total	271,575,600

The commerce of the United States of America has already advanced to an extent which rivals that of some of the principal states of Europe, and, in all probability, will materially affect many of the long-established channels of trade. The destination of the exports of the United States is principally to the West Indians, Great Britain, France, Holland, and Spain; but some smaller branches of their commerce begin to appear in all the trading parts of the world. The following statement shows the proportions of the exports of 1804 to the dominions of each power:

	Dollars.
To Great Britain and Ireland	12,206,501
the British colonies	9,623,301
Holland and the Dutch colonies	16,447,417
France and colonies	12,776,111
Spain and colonies	6,728,125
Hamburgh, Bremen, &c.	4,475,007
Denmark and colonies	3,346,623
Sweden`	691,975
Prussia	1,186,116
Portugal and colonies	2,496,858
Italy	1,671,149
Trieste, and other Austrian ports	333,798
Europe generally	620,891
Turkey, the Levant, and Egypt	44,646
Morocco and the Barbary states	9,333
Cape of Good Hope	167,917
Africa generally	349,036
China	198,601
East Indies generally	796,316
South Seas	10,000
North-west coast of America	196,059
West Indies generally	3,324,294
Total	77,699,074

This total is more than double the amount of the exports of America ten years prior to the above period; and the whole increase of the trade of the States since they ceased to be British colonies, has been such as never before took place in any country. The proportion of the exports, consisting of produce or manufactures of the United States, and of foreign merchandize, was as follows:

	Dollars.
Domestic produce	41,467,477
Foreign	36,231,597
Total	77,699,674

On converting the totals of the accounts of the exports of France and America into British money, their respective amounts will stand thus:

	L.
Exports of Great Britain in 1800	43,152,019
Exports of France in 1800	11,315,650
Exports of the American States in 1804	17,482,291

Had the comparison been made with the real value of the exports of Great Britain instead of the custom-house value, the superior extent of our foreign trade would have appeared still more striking.

EXPOSITION, in general, denotes the setting a thing open to public view: thus it is the Romanists say, the host is exposed, when shown to the people.

EX POST FACTO, in law, something done after another: thus an estate granted may be good by matter ex post facto, that was not so at first, as in case of election.

A law is said to be ex post facto when it is enacted to punish an offence committed before the passing of the law. Such a proceeding is held to be against the constitution of England.

EXPRESSED OILS, in chemistry, such oils as are obtained from bodies only by pressing. See Oil.

EXPRESSION, in chemistry, or pharmacy, denotes the act of pressing out the juices or oils of vegetables, which is one of the three ways of obtaining them; the other two being by infusion and decoction. See Pharmacy.

Expression, in painting, is the distinct exhibition of character in the general object of the work, or of sentiment in the characters or persons represented.

In the latter case it consists either in representing the body in general and all its parts severally, in actions most peculiarly suitable to the design of the picture, and marking thereby the emotions of the soul in the various figures, or in pourtraying in the face the appearances of the passions. In this sense the term expression has been frequently confounded with passion; but the former implies a representation of its object agreeably to its nature and character, and to the office it holds on the picture; while the latter denotes merely a particular turn or motion of the body, or of the muscles and features of the face, which marks any violent agitation of the soul: so that every passion is an expression, but not every expression a passion.

Expression, says Le Brun, is a lively and natural resemblance of the objects which we are to represent. It is a necessary ingredient in every part of painting, and without it no picture can be perfect, as it is that which describes the true characters of things. It is by expression that the different natures of bodies are distinguished, that the figures seem to have motion, and that every thing counterfeited appears to be real.

Expression subsists as well in the colouring as in the design; it is to be observed in the representation of landscapes, as well as in the general composition of figures.

All substances, whether animate or inanimate, are capable of expression. The skill of the painter exhibits the hardness of one substance and the softness of another, its smoothness or roughness, its dryness or moistness, clearness or opaqueness, &c. in characters which cannot be mistaken.

Expression being therefore a representation of things according to their character, may be considered either with respect to the subject in general, or to the passions peculiarly relative to it.

1st. With regard to the subject; it is first requisite that all and every part of the composition should be so adapted to the general character of the subjects that they should conspire to impress at the same moment one distinct sentiment or idea. Thus, for example, in a picture designed to give the representation of a joyful or peaceful event, every object that is introduced should be of a pleasing or tranquil kind. If the subject be taken from history, its particular nature and character must be diffused through every part of the work; but wherever any circumstance occurs, which counteracts or diminishes the general sentiment raised by the event represented, the insertion of such circumstance will, proportionably to its magnitude, destroy the general expression of the picture.

Extraneous incidents are frequently introduced for the purpose of diversifying and giving variety to the expression; but they must be such as are neither contrary to the truth of the history, nor to the principal design of the subject.

Expression, in a picture, will then be perfect when every part of the picture is not only fit and appropriate to the subject, but when no one part of it could without evident impropriety be transferred to any other subject.

The agreement of the whole ought to be particularly regarded, not only in the actions of the figures, but in the back-ground, light and shade, and colouring. Whatever is the general character of the subject, whether serene, joyous, melancholy, grave, solemn, or terrible, the picture should discover that character to the first glance of the spectator. The nativity of a Saviour, his resurrection or ascension, must be distinguished from his crucifixion or his interment, as much by the general hue of the picture, the accessory ornaments, back-ground, &c. as by the action of the figures. In viewing same of the finest religious subjects of the Italian school, sentiments of awe and devotion have been often experienced to be amongst the first impressions made on the spectator, previous to his examination of the particular actions or countenances of the figures, and therefore evidently produced by the general distribution of the composition, or the general tone of the colouring. The works of Ludovico Caracci are justly celebrated by sir J. Reynolds in his academic discourses, for their powerful effect in the latter point.

In the admirable cartoon by Raffaelle, of St. Paul preaching at Athens, the expression of the whole work is just and strong. The dignified air of the apostle impresses the spectator with reverence. His action is awful and authoritative without excess or extravagance: it is an action which assures us that he, who uses it, speaks with a power of conviction. The different sentiments of his audience are exhibited with equal skill and good sense. Some of his hearers appear angry, some malicious, some attentive, some reasoning with themselves on his doctrines, some disputing their truth, and some convinced. The very back-ground has its meaning: it contributes to the demonstration or expression of that superstition, against which the inspired orator directed his eloquence. In the power of distinct, peculiar, and appropriate expression, no one has ever raised himself above Raffaelle, scarcely any one has ever equalled him.

There are often certain little circumstances which contribute to the expression of the general subject, and of these also no painter ever availed himself more than Raffaelle; witness the burning lamps, in the cartoon of the Apostles healing at the beautiful Gate of the Temple, where they have the effect of expressing the holy uses, no less than the magnificence, of the building in which they are hung.

The robes or other habits of the figures, their attendants, their engines of authority, crowns, maces, swords; or, in humble life, their various implements of labour, crooks, scythes, &c. all contribute to the expression of character.

There are also various kinds of accessory aids, which form a mode of artificial expression, indulged to painters, and practised by them. To express the sensations of the mind of Christ, when in agony a short while previous to his crucifixion, Baroccio has not only represented the angel offering him the cup of bitterness, but has painted in the back-ground the cross encircled with flames.

In the same manner in the cartoon where the people of Lycaonia are going to offer sacrifices to St. Paul and Barnabas, Raffaelle has shown the cause of their offerings, by adventitious figures. In the fore-ground, the man who had been healed of lameness by those apostles, is the most eager to express his sense of the miraculous power exercised by them, and the individuality of this character is marked not only by a crutch on the ground under his feet, but by the more singular circumstance of an old man taking up the skirt of his garment, looking on the limb which he may be supposed to have remembered in its former crippled state, and expressing his admiration and devotion.

Of the same kind was the artifice used by the Greek painter Timanthes (and so much admired by the ancients), to express the prodigious bulk of a cyclops. He placed round the sleeping monster several satyrs, supposed to be of the ordinary size of the human form, one of whom was measuring the thumb of the giant with his thyrsus, apparently with great caution, lest he should awake; others were running away, as if frightened; others gazing on him from a distance, as not daring to approach him.

Another artificial mode of expression, practised by painters, is the use of allegorical figures, representative of certain points of the subject. This art has also been derived from the ancients, who have left abundant examples of it; as in the bas-reliefs on the Antonine column at Rome, where the figure of Jupiter Pluvius is introduced to express the rain which fell when the Roman army was preserved by the prayers of the Theban legion. Raffaelle, in this manner, has personified the river Jordan in his design of the children of Israel pass-

ing across the river of that name: and has represented him as pushing back and restraining the course of the waters with his arm.

2dly. With regard to the passions and affections peculiar to the subject, the general rules consist in the proper division and distinction of them, as shown in brute or rational animals, in young or old, in male or female, in cultivated or savage.

The passions of brutes are few and simple; those of the rational animal many and various. The powers of expression in the one are more confined than in the other. A man can move his eyebrows more readily than the brutes, and can give greater variety to the direction of the eyes, &c.

Children and savages, less accustomed to the use of reason, express their passions more directly than cultivated men; the first necessarily, without habitual modes of disclosure or disguise.

Respecting the difference of age and sex, the expressions of vigorous manhood wear a freer, bolder, and more resolute appearance; those of women, and age, are more tender, reserved and feeble.

Condition or rank of life also demands a difference of expression. The demeanour of a magistrate, or other person invested with public honours, is more grave and reserved than that of the populace, whose external motions are, for the most part, rude and disorderly.

The several expressions of action, in running, striking, pointing, asking, forbidding, affirming, idling, avoiding, pursuing, starting, and many other modes, are obviously various, and require a fitness of attitude, and a proper delineation of the corresponding and assisting parts of the body, and other accessories.

For the painter of animals nothing is more necessary than the study of the characteristic expressions of the brute creation, which are severally as various as their species; not only on account of the singular diversity of qualities and instincts with which they are endowed, but of the different modes in which they exhibit passions of a similar nature. Expression in brute animals is, generally speaking, more displayed by attitude than by the features of the face, although, in part, this probably arises from our imperfect acquaintance with them.

As it is therefore in the human figure, and still more particularly in the human countenance, that expression is most effectually and exquisitely displayed, it is to man that our observations must be principally directed in this part of the subject, for the study of which there is no perfect school but that of nature. If the rules of expression generally given are found to agree with the experience of a careful observer of nature, they are good and useful; if not, they are to be followed with caution, or rejected wholly, as occasion shall dictate.

The affections of the soul may be expressed by attitude, and by countenance. There are few strong emotions of our minds which may not, in a great measure, be shown by the former. Fear, surprise, horror, admiration, humility, pride, and many other affections, are visible in the air and turn of the body; but as this mode of expression admits of a very extensive range, it is next to impossible to define the precise rules by which it is to be governed.

Next to the general action of the body, and turn or air of the head, the hands claim a principal share in the expression of our sentiments. It is by them we approve, refuse, entreat, admonish. The hands raised together towards heaven express devotion; folded they denote idleness, and sometimes despair; wringing the hands denotes grief; waving one hand from us, prohibition; extending it towards any one, acceptance and benevolent intentions; laying the fore-finger on the mouth enjoins silence; the same finger extended while the others are closed in the hand, shows and points to a particular object.

That by the countenance the particular and immediate disposition of our minds is indicated, is indisputable; and not this only, but our general qualities and capacities are to be found by the same index. Let two men, a wise man and a fool, be placed together, dressed and disguised as you please, one will never be mistaken for the other; nay, the distinction between them will be discernible at the first glance of the eye: and as these characters are most strongly stamped upon the face so as to be read by every spectator, when they are in the utmost extremes, they are proportionally impressed as they exist in a greater or less degree, and are legible accordingly, in proportion to the skill and sagacity of the reader.

In the same manner our good or ill-nature, our gentleness, ferocity, humility, pride, are discoverable in the countenance in all their various degrees. The lines and forms by which these general tendencies, or settled habits of our minds, are expressed, are, of all others, the most difficult to be defined. The reader will find many curious hints and essays concerning them in the works of Lavater.

With regard to the temporary affections of the mind, the following rules of expression are ordinarily given:

Although the passions of the soul may be expressed by the actions of the body, it is in the face that they are principally shown, and particularly in the turn of the eye, and motion of the eyebrows.

There are two ways of elevating the eyebrows; the one at the middle, which likewise draws up the corners of the mouth, and argues pleasurable emotions; the other at the point next the nose, which likewise draws up the middle of the mouth, and is the mark of grief and painful sensations.

The passions are all reducible to joy and sadness, either mixed or simple.

Joy causes a dilatation of all the parts of the face; the eyebrows rise in the middle, the eyes are half-open and smiling, the pupils sparkling and moist, the nostrils a little open, the cheeks full, the corners of the mouth drawn upwards, the lips red, the complexion lively, the forehead serene.

Passionate joy, proceeding from love, is shown by the forehead smooth and even, the eyebrows a little elevated on the side to which the pupil is turned, the eyes sparkling and open, the head inclined towards the object, the air of the face smiling, and the complexion ruddy.

Joy proceeding from desire, is expressed by the air and action of the body, the arms extending towards the object in uncertain and unquiet motions.

Sadness is expressed by the body being bent downwards, the head neglectfully reclined, the forehead

wrinkled, the eyebrows raised to the middle of the forehead, the eyes half-shut, the mouth a little open, the corners tending downwards, the under lip pointing and drawn back, the nostrils swelled and drawn downwards.

Sadness, mixed with fear, causes the parts to contract and palpitate, the members to tremble and fold up, the visage to be pale and livid, the point of the nostrils elevated, the pupil in the middle of the eye, the mouth opened at the sides, and the under-lip drawn back.

In sadness, mixed with anger, the motions are more violent, the parts all agitated, the muscles swelled, the pupil wild and sparkling, the point of the eyebrows fixed toward the nose, the nostrils open, the lips swelled and pressed down, the corners of the mouth a little open and foaming, the veins swelled and full, and the hair erect.

Sadness, mixed with despair, has a similar appearance to the last mentioned, only more excessive and disordered.

But, added to these general observations, every passion has its distinct form of expression, for which see the article PASSIONS.

It is remarkable that Leonardo da Vinci in his Treatise on Painting, has observed, that between the expression of laughing, and that of weeping, there is no difference in the motion of the features, either in the eyes, mouth, or cheeks, but in the brows only; those who weep, raising the brows and bringing them close together above the nose, and forming many wrinkles on the forehead, while those who laugh have them elevated and extended.

Of expression in sculpture, sir Joshua Reynolds has given it as his opinion that it is necessarily of a much more confined kind than in painting; an assertion which cannot be disputed, inasmuch as the materials of sculpture are more limited. He instances the celebrated group of Laocoon and his sons, in which he says the whole expression consits in the representation of bodily pain in general, and asserts that sculpture is incapable of admitting the mixed delineation of pain and parental affection.

This doctrine, if not highly questionable, certainly demands a greater degree of elucidation.

EXTASY, in medicine, a species of catalepsy, when a person perfectly remembers, after the paroxysm is over, the ideas he conceived during the time it lasted.

EXTEND, in law, signifies to value the lands or tenements of a person bound by a statute, &c. who has forfeited the same at such an indifferent rate, that by the yearly rent the creditor in time may be paid his debt. See EXTENT.

EXTENSION, in philosophy, one of the common and essential properties of a body, or that by which it possesses or takes up some part of universal space, which is called the place of that body.

EXTENSOR, an appellation given to several muscles, from their extending or stretching the parts to which they belong.

EXTENT, in law, is used in a double sense: sometimes it signifies a writ or command to the sheriff for the valuing of lands or tenements; and sometimes the act of the sheriff, or other commissioner, upon this writ; but most commonly it denotes an estimate or valuation of lands, and hence come our extended or rack rents. Every extent ought to be made on inquisition and verdict, without which the sheriff cannot legally execute the writ.

The cognisee, or party to whom the lands are delivered, has no absolute property in them, but is accountable to the cognisor according to the extended value only, not the real value. No seisin can be on an extent, nor may lands or goods be sold thereon.

EXTERMINATION, in general, the extirpating or destroying something. In algebra, surds, fractions, and unknown quantities, are exterminated by the rules for reducing equations. See ALGEBRA.

EXTINGUISHMENT, in law: wherever a right, title, or interest is destroyed, or taken away by the act of God, operation of law, or act of this party, this is called an extinguishment.

Of the extinguishment of rents.—If a lessor purchases the tenancy from his lessee, he cannot have both the rent and the land; nor can the tenant be under any obligation to pay the rent when the land, which was the consideration thereof, is returned by the lessor into his own hands; and this resumption or purchase of the tenantcy makes what is properly called an extinguishment of the rent.

As to the extinguishment of copyholds, it is laid down as a general rule, that any act of the copyholder, which denotes his intention to hold no longer of his lord, amounting to a determination of his will, is an extinguishment of his copyhold. Hutt. 81.

Of the extinguishment of common.—If a commoner release his common in one acre, it is an extinguishment of the whole common. Show. 350.

Of the extinguishment of debts.—A creditor's accepting a higher security than he had before is an extinguishment of the first debt; as if a creditor by simple contract accepts an obligation, this extinguishes the simple-contract debt. 1 Rol. Abr. 470 and 471.

EXTINGUISHMENT OF SERVICES. The lord purchases or accepts parcel of the tenantcy, out of which an entire service is to be paid or done; by this the whole service will be extinct; but if the service is pro bono publico, then no part of it shall be extinguished; and homage and fealty are not subject to extingushment by the lord's purchasing part of the land. 6 Rep. 105.

EXTINGUISHMENT OF WAYS. If a man has a highway as appendant, and after purchases the land wherein this way is, the way is extinct: though a way of necessity, to market, or to church, or to arable land, &c. is not extinguished by purchase of grounds, or unity of possession. 1 Inst. 155.

EXTORTION, signifies any oppression by colour or pretence of right; and in this respect it is said to be more heinous than robbery itself, as also that it is usually attended with the aggravating sin of perjury. Co. Lit. 368.

At common law extortion is severely punishable at the king's suit by fine and imprisonment, and by a removal from the office in the execution whereof it was committed. 31 Eliz. c. 5. And this statute adds a greater penalty than the common law gave; for hereby the plaintiff shall recover his double damages. 2 Inst. 210. See COLOUR OF OFFICE.

EXTRACT, in pharmacy, is a solution of the purer

parts of a mixed body inspissated, by distillation or evaporation, nearly to the consistence of honey. See PHARMACY.

EXTRACTION, in surgery, is the drawing any foreign matter out of the body by the hand, or by the help of instruments. See SURGERY.

EXTRACTION OF ROOTS, in algebra and arithmetic, the method of finding the root of any power or number. See ALGEBRA, and ARITHMETIC.

EXTRACTOR, in midwifery, an instrument, or forceps, for extracting children by the head. See MIDWIFERY.

EXTRA-JUDICIAL, is when judgment is given in a cause or case not depending in that court where such judgment is given, or wherein the judge has no jurisdiction.

EXTRA-PAROCHIAL, out of any parish; privileged or exempted from the duties of a parish. If a place is extra-parochial, and has not the face of a parish, the justices have no authority to send any poor person thither: possibly a place extra-parochial may be taxed in aid of a parish, but a parish shall not in aid of that. 2 Salk. 486.

EXTRAVAGANTES, those decretal epistles which were published after the Clementines. They were so called because, at first, they were not digested or ranged with the other papal constitutions, but seemed to be detached from the canon law. They continued to be called by the same name when they were afterwards inserted in the body of the canon law. The first extravagantes are those of John XXII. successor of Clement V.: the last collection was brought down to the year 1483, and was called the common extravagantes, notwithstanding that they were likewise incorporated with the rest of the canon law.

EXTRAVASATION, in contusions, fissures, depressions, fractures, and other accidents of the cranium, is when one or more of the blood-vessels that are distributed on the dura mater, are broken or divided, whereby there is such a discharge of blood as greatly oppresses the brain, and disturbs its offices; frequently bringing on violent pains and other mischiefs, and at length death itself, unless the patient is timely relieved. See SURGERY.

EXTREMES, in logic, the terms expressing the two ideas whose relation we inquire after in a syllogism.

EXTREME *and mean proportion*, in geometry, is when a line AB (Plate LIV. Miscel. fig. 88) is so divided in F, that the rectangle under the whole line AB, and the lesser segment FB, is equal to the square of the greater segment AF.

Let a square be formed upon the line AB, and one of its sides AC be equally divided in the point D; draw DB, and take the line DG equal to the line BD; then the square AGHF will be equal to the rectangle FE.

For since the line AC is equally divided in the point D, and is lengthened by the line AG, the rectangle CH, together with the square of the line AD, will (by 6. 2. El.) be equal to the square of the line DG or DB. But the square AE, with the square of the line AD, is also equal (47. 1.) to the square of the line DB. Therefore the square AE is equal to the rectangle CH. Taking then away from both the rectangle CF, the rectangle FE will be equal to the square FG.

But no number can be so divided into two parts, as is demonstrated by Clavius, in his commentaries upon lib. 9. of Euclid; which is evident enough thus: Let a be the number, and x the greater part; then the lesser part will be $a - x$, and so $aa - ax = xx$, and thence $x = \frac{a + a\sqrt{5}}{2}$; and since the square root of 5 cannot be had in numbers exactly, it is plain that the value of x partly consisting of the square root, multiplied by a, cannot be had exactly in numbers neither.

EXTREMES *conjunct and disjunct*. See TRIGONOMETRY, *spherical*.

EXUVIÆ, among naturalists, denote the cast-off parts or coverings of animals, as the skins of serpents, caterpillars, and other insects. See ERUCA.

EYE, in anatomy, the organ of sight, or that part of the body whereby visible objects are represented to the mind. See ANATOMY, OPTICS, and PHYSIOLOGY.

Motions of the eye are either external or internal. The external motion is that performed by its four straight and two oblique muscles, whereby the whole globe of the eye changes its situation or direction. The spherical figure of our eyes, and their loose connection to the edge of the orbit by the tunica conjunctiva, which is soft, flexible, and yielding, does excellently dispose them to be moved this or the other way, according to the situation of the object we could view. By the membranes the eye is connected to the edge of the orbit, which being soft and flexible, they do in such a manner as not in the least to impede its necessary motions; and that great quantity of fat placed all round the globe, betwixt it and the orbit, lubricates and softens the eye, and renders its motions more easy: hence arise the three following remarkable observations:

1. When nature has denied the head any motion, it is observable that she has, with great care and industry, provided for this defect. To this purpose belongs the surprising beautiful and curious mechanism observable in the immoveable eyes of flies, wasps, &c. They nearly resemble two protuberant hemispheres, each consisting of a prodigious number of other little segments of a sphere, all which segments are perforated by a hole, which may be called their pupil, in which this is remarkable; that every foramen, or pupil, is of a lenticular nature, so that we see objects through them topsy-turvy, as through so many convex glasses: they even become a small telescope, when there is a due focal distance between them, and the lens of the microscope by which they are viewed. Leuwenhoek's observations make it probable that every lens of the cornea supplies the place of the crystalline humour, which seems to be wanting in those creatures; and that each has a distinct branch of the optic nerve answering to it, upon which the images are pointed: so that as most animals are binocular, and spiders for the most part octonocular, so flies, &c. are multocular, having in effect as many eyes as there are perforations in the cornea, by which means (as other creatures with but two eyes are obliged, by the contraction of the muscles above-enumerated, to turn their eyes to objects) these have some or other of their pupils always ready placed towards objects nearly all around them, whence they are so far from being denied any benefit of this noble and most necessary sense of sight,

that they have probably more of it than other creatures, answering to their necessities and ways of living.

II. As in man and most other creatures, the eyes are situated in the head, because among other reasons, it is the most convenient place for their defence and security, being composed of hard bones, wherein are formed two large strong sinuses, or sockets, commonly called orbits, for the convenient lodgings of these tender organs, and securing them against external injuries: so in those creatures whose head, like their eyes and the rest of their body, is soft and without bones, nature has provided for this necessary and tender organ a wonderful kind of guard, by enduing the creature with a faculty of withdrawing his eyes into his head, and lodging them in the same safety within his body. We have a very beautiful example of this in snails, whose eyes are lodged in four horns, like stramentous spots, one at the end of each horn, which they can retract at pleasure, when in any danger. Hence it may be also observed, that the cornea in all animals that want eyelids, as fishes, exactly resembles in hardness the horn of a lanthorn; and therefore is not hurt by such particles as their eyes are commonly exposed to. And in the mole, because this animal lives under ground, it was necessary its eyes should be well guarded and defended against the many dangers and conveniences to which its manner of living exposes it: this is the reason why its eyes are so small, and that they are situated so far in the head, and covered so strongly with hair; and besides they can protrude and retract them at pleasure. See Comparative Anatomy.

III. The third and last reflection we shall make upon the external motion of our eyes, is what regards a problem which has very much perplexed both physicians and philosophers, viz. What is the cause of the uniform motion of both eyes?

In some creatures, such as fishes, birds, and among quadrupeds, the hare, cameleon, &c. the eyes are moved differently; the one towards one object, and the other towards another. But in man, sheep, oxen, and dogs, the motions are so uniform that they never fail to turn both towards the same place: hence in operations upon the eye that require it to be kept immoveable, sometimes it is necessary to tie up the sound eye with a compress, by which means the other is easier kept fixed and immoveable.

The final cause of this uniform motion is, 1. That the sight may be thence rendered more strong and perfect: for since each eye apart impresses the mind with an idea of the same object, the impression must be more strong and lively when both eyes concur; and that both may concur, it is necessary that they move uniformly; for though the retina, or immediate organ of vision is expanded upon the whole bottom of the eye, as far as the ligamentum ciliare, yet nothing is clearly and distinctly seen but what the eye is directed to. 2. A second advantage we reap from the uniform motion of the eyes, which is more considerable than the former, consists in our being thereby enabled to judge with more certainty of the distance of objects. See Optics.

There is yet another advantage, full as considerable as any of the former, that is thought to arise from the uniform motion of our eyes, and that is, the single appearance of objects seen with both our eyes; which, though at first view it does not appear probable, is true: for if in looking at an object you turn one of your eyes aside with your finger, and alter its direction, every thing will be seen double.

By the internal motions of the eye we understand those motions which only happen to some of its internal parts, such as the crystalline and iris; or to the whole eye when it changes its spherical figure, and becomes oblong or flat. The internal motions of our eyes are either such as respect the change of conformation that is necessary for seeing distinctly at different distances, or such as only respect the dilatation and contraction of the pupil.

That our eyes change their conformation, and accommodate themselves to the various distances of objects, will be evident to any person, who but reflects on the manner and most obvious phenomena of vision.

Authors are very much divided in their opinions with regard to the mechanism by which this change is introduced, as well as what parts it consists in: for some are of opinion that the whole globe changes its form, by being lengthened into an oblong figure when objects are near, and by becoming flat when they are removed to a greater distance; and others are of a quite contrary opinion.

With regard to the change of the crystalline, and the mechanism by which it is produced, some maintain, that according as objects are at different distances this humour becomes more or less convex, which does indeed very well account for distinct vision at different distances; since objects whose rays are admitted through a lens placed in the hole of a window-shutter, in a dark room, have their images always distinct, at whatever distance they may be from the window, provided the lens is of a convexity answerable to that distance.

Eye, in architecture, is used to signify any round window, made in a pediment, an attic, the reins of a vault, &c.

Eye *of a dome*, an aperture at the top of a dome, as that of the Pantheon at Rome, or of St. Paul's at London: it is usually covered with a lanthorn.

Eye *of the volute*, in architecture, is the centre of the volute, or that point in which the helix, or spiral of which it is formed, commences: or it is the little circle in the middle of the volute, in which are found the thirteen centres for describing the circumvolutions of it.

Eye, in agriculture and gardening, signifies a little bud or shoot inserted into a tree by way of graft.

Eyebright. See Euphrasia.

Eye *of the anchor*, on board a ship, the hole in which the ring of the anchor is put into the shank.

Eye *of the strap*, on board a ship, the ring or round which is left to the strap to which any block is seized.

Eye, in printing, is sometimes used for the thickness of the types; or, more properly, it signifies the graving in relievo on the top of the letter, otherwise called its face: the eye of the *e* is the small opening at the head of that letter, which distinguishes it from the *c*.

Eye-glass, in the microscope. See Microscope.

EYRE, or *eire*, in law, the court of itinerant justices. See Justices.

EZAN, in the Mahometan theology, a hymn containing the profession of their faith, which is repeated five times a day, to call the people to prayers.

EZEKIEL'S REED, or ROD, a measure of length mentioned by that prophet, and computed to be nearly equal to two English feet.

F.

F, the sixth letter of the alphabet. As a numeral it denotes 40, and with a dash over it thus $\overline{F}$, denotes 40,000: in music it stands for the bass-clef; and frequently for forte, as *ff* does for forte forte.

F, in medicine, stands for fiat, let it be done: thus F. S. A. stands for fiat secundum artem, let it be done according to art.

As an observation, F stands for filius, fellow, &c.: thus F. R. S. signifies Fellow of the Royal Society.

FA, in music, one of the syllables invented by Guido Aretine, to mark the fourth note of the modern scale, which rises thus, ut, re, mi, fa. Musicians distinguish two fa's, viz. the flat, marked with a *b*, or ♭, and the sharp or natural, marked thus ✱, and called biquadro.

FA FINTO, a feigned F, or a feint upon that note: this is the case of every note that has the mark ♭ before it; but more especially mi and si, or our E and B, and is what we commonly call the flat of any note.

FABA, the *bean*. See VICIA.

FABLE, *fabula*, a tale or feigned narration, designed either to instruct or amuse, disguised under the allegory of an action, &c. Fables were the first pieces of wit that made their appearance in the world, and have been still highly valued, not only in times of the greatest simplicity, but among the most polite ages of the world. Jotham's fable of the trees is the oldest that is extant, and as beautiful as any that has been made since. Nathan's fable of the poor man is next in antiquity, and had so good an effect as to convey instruction to the ear of a king. We find Æsop in the most distant ages of Greece; and in the early days of the Roman commonwealth, we read of a mutiny appeased by the fable of the belly and the members. There is scarcely a book in the whole compass of profane literature which contains a greater store of moral wisdom, frequently seasoned with no small share of wit, than Æsop's fables. It is injudiciously put into the hands of children who cannot understand it: its object is to instruct men.

FABLE is also used for the plot of an epic or dramatic poem; and is, according to Aristotle, the principal part, and the soul of a poem. See POETRY.

FABRIC-LANDS, those formerly given towards rebuilding or repairing of cathedrals and other churches; for anciently almost every body gave more or less, by his will, to the fabric of the parish-church where he dwelt.

FACE, or *facade*, in architecture, the front of a building, or the side which contains the chief entrance. Sometimes, however, it is used for whatever side presents to the street, garden, court, &c. or is opposite to the eye.

FACE *of a stone*, in masonry, that superficies of it which lies in the front of the work. The workmen generally choose to make one of those sides the face, which, when in the quarry, lay perpendicularly to the horizon, and consequently the breaking, not the cleaving way of the stone.

FACE, in fortification, an appellation given to several parts of a fortress, as the face of a bastion, &c. See FORTIFICATION.

FACE, in the military art, a word of command, intimating to turn about: thus, "Face to the right," is to turn upon the left heel a quarter-round to the right; and "Face to the left," is to turn upon the right heel a quarter-round to the left.

FACET, or *facette*, among jewellers, the name of the little faces or planes to be found in brilliant and rose diamonds.

FACTION, in antiquity, a name given to the different companies of combatants or racers in the circus. They were four, viz. the white, the red, the green, and the blue; to which Domitian added another of purple colour. They were so denominated from the colour of the liveries they wore, and were dedicated to the four seasons of the year, the green being consecrated to spring, the blue to winter, the red to summer, and the white to autumn. It appears from ancient inscriptions that each faction had its procurators and physician; and from history, that party rage ran so high among them, that in a dissension between two factions, in the time of Justinian, almost forty thousand men lost their lives in the quarrel. See Gibbon's Decline and Fall, &c.

FACTITIOUS, any thing made by art, in opposition to what is the produce of nature. Thus, factitious cinnabar is opposed to native cinnabar.

FACTOR, in commerce, is an agent or correspondent residing beyond the seas, or in some remote part, commissioned by merchants to buy or sell goods on their account, or assist them in carrying on their trade.

A factor receives from the merchants, his constituents, in lieu of wages, a commission or factorage, according to the usage of the place where he resides, or the business he transacts, this being various in different countries, and on the purchases and sales of different commodities. He ought to keep strictly to the tenor of his orders; as a deviation from them, even in the most minute particular, exposes him to make ample satisfaction for any loss that may accrue from his nonobservance of them; and it is very reasonable it should be so, as the distance of his situation renders him unable to judge of his principal's views and intention. When unlimited orders are given to factors, and they are left to sell or buy on the best conditions they can, whatever detriment occurs to their constituents, they are excused, as it is to be presumed they acted for the best, and were governed by the dictates of prudence. But a bare commission to sell is not sufficient authority for the factor to trust any person, wherefore he ought to receive the money on the delivery of the goods; and, by the general power, he may not trust beyond one, two, or three months, &c. the

usual time allowed in sales, otherwise he shall be answerable out of his own estate. If a factor sells on the usual trust to a person of good credit, who afterwards becomes insolvent, he is discharged; but not if the man's credit was bad at the time of sale. If a factor gives a man time for payment of money contracted on sale of his principal's goods, and, after that time is elapsed, sells him goods of his own for ready money, and the man becomes insolvent, the factor in equity ought to indemnify his principal, but he is not compellable by the common law. A factor should always be punctual in the advices of his transactions, in sales, purchases, freights, and more especially in draughts by exchange: he should never deviate from the orders he receives in the execution of a commission for purchasing goods, either in price, quality, or kind; and if, after goods are bought, he sends them to a different place from what he was directed to, they must remain for his own account, except the merchant, on advice of his proceedings, admits them according to his first intention. A factor that sells a commodity under the price he is ordered, shall be obliged to make good the difference: and if he purchases goods for another at a price limited, and afterwards they rise, and he fraudulently takes them for his own account, and sends them to another part, in order to secure an advantage that seemingly offers, he will, on proof, be obliged, by the custom of merchants, to satisfy his principal for damages. If a factor, in conformity with a merchant's orders, buys with his money, or on his credit, a commodity he shall be directed to purchase; and, without giving advice of the transaction, sells it again to profit, and appropriates to himself the advantage; the merchant shall recover it from him, and besides have him amerced for his fraud. When factors have obtained a profit for their principal, they must be cautious how they dispose of it; for if they act without commission they are responsible: and if a merchant remits goods to his factor, and about a month after draws a bill on him, the factor, having effects in his hands, accepts the bill, then the principal breaks, and the goods are seized in the factor's hands for the behalf of the creditors, it has been conceived the factor must answer the bill notwithstanding, and come in as a creditor for so much as he was obliged, by reason of his acceptance, to pay. A factor who enters into a charterparty with a master for freight, is obliged by the contract; but if he loads aboard generally, the principal and the lading are liable for the freight, and not the factor. If a factor, having money in his hands belonging to his principal, neglects to insure a ship and goods, according to order, if the ship miscarry, the factor, by the custom of merchants, shall make good the damage; and if he makes any composition with the insurers after insurance without orders so to do, he is answerable for the whole insurance.

As fidelity and diligence are expected from the factor, so the law requires the like from the principal; if, therefore, a merchant remits counterfeit jewels to his factor, who sells them as if true; if he receives loss or prejudice by imprisonment or other punishment, the principal shall not only make full satisfaction to the factor, but to the party who bought the jewels.

What is here said of factors, is meant of such as reside abroad to act for merchants; and may be applied to supercargoes, who go a voyage to dispose of a cargo, and afterwards return with another to their principals; but it is also the custom of the merchants of the highest credit throughout the world to act mutually in the capacity of factors for each other. The business so executed is called commission-business, and is generally desirable by all merchants, provided they have always effects in their hands, as a security for all the affairs which they transact for the account of others. And this class of traders of established reputation, have current as well as commission accounts, constantly between them; and draw on, remit to, and send commissions to each other only by the intercourse of letters, which, among men of honour, are as obligatory and authoritative as all the bonds and ties of law.

Factor, in multiplication, a name given to the multiplier and multiplicand, because they constitute the product.

FACTORAGE, called also commission, is the allowance given to factors by the merchant who employs them. A factor's commission in Britain, on most kinds of goods, is two and a half per cent.: on lead, and some other articles, two per cent.; in Italy, two and a half per cent.; in France, Holland, Spain, Portugal, Hamburgh, and Dantzic, two per cent.; in Turkey three per cent.; in North America five per cent. on sales, and five per cent. in returns; in the West Indies eight per cent. for commission and storage. In some places it is customary for the factors to insure the debts for an additional allowance, generally one and a half per cent. In that case they are accountable for the debt when the usual term of credit is expired. Factorage on goods is sometimes charged at a certain rate per cask, or other package, measure or weight, especially when the factor is only employed to receive or deliver them.

FACTORY is a place where a considerable number of factors reside, to negotiate for their masters or employers. The most considerable factories belonging to the British are those established in the East Indies, Portugal, Turkey, &c.

FACULÆ, in astronomy, certain bright and shining parts, which the modern astronomers have, by means of telescopes, observed upon or about the surface of the sun: they are but very seldom seen.

Hevelius assures us that, on July 20, 1634, he observed a facula, whose breadth was equal to a third part of the sun's diameter. He says too that the maculæ often change into faculæ, but these seldom or never into maculæ. And some authors even contend that all the maculæ degenerate into faculæ before they quite disappear. Many authors, after Kircher and Scheiner, have represented the sun's body full of bright, fiery spots, which they conceive to be a sort of volcanoes in the body of the sun; but Huygens, and others of the latest and best observers, finding that the best telescopes discover nothing of the matter, agree entirely to explode the phenomena of faculæ. All the foundation he could see for the notion of faculæ, he says, was, that in the darkish clouds which frequently surrounded the maculæ, there are sometimes seen little points or sparks brighter than the rest.

FACULTY, in law, a privilege granted to a person, by favour and indulgence, of doing what, by law, he ought not to do. For granting these privileges there is

a court under the archbishop of Canterbury, called the court of the faculties, the chief officer of which is styled master of the faculties, who has a power of granting dispensations in divers cases: as to marry without the bans being first published; to ordain a deacon under age; for a son to succeed his father in his benefice; a clerk to hold two or more livings, &c.

FACULTY, in the schools, a term applied to the different members of an university, divided according to the arts and sciences taught there: thus in most universities there are four faculties, viz. 1. Of arts, which include humanity and philosophy. 2. Of theology. 3. Of physic. And, 4. Of civil law. The degrees in the several faculties in our universities are those of bachelor, master, and doctor.

FACULTY OF ADVOCATES, a term applied to the college or society of advocates in Scotland, who plead in all actions before the court of sessions. They meet in the beginning of every year, and choose the annual officers of the society, viz. dean, treasurer, clerks, private and public examinators, and a curator of their library. The manner of admission into the faculty of associates is by a trial in the civil law, and Scotch law: the person desiring to be admitted having, upon petition, obtained a recommendation to the dean of the faculty, he gives a remit to the private examinators, who are nine in number, and who, after their election, having divided the body of the civil law into nine parts, each taking one, appoint a diet for examination: in this diet there must be at least seven present, each of whom examines the candidate; and the question being afterwards put, Qualified, yea or no? they give their opinion by balloting, upon which the candidate is either admitted by signing his petition, or remitted to his studies. After the private trial the dean of the faculty assigns the candidate a title of the civil law, for the subject of a thesis; which being distributed among the advocates, the faculty meet on a day appointed, when three at least of fifteen public examinators dispute against the thesis; and afterwards the faculty give their opinions by balloting, as in the private trial. If the candidate is found qualified, the dean assigns him a law for an harangue before the lords; which harangue being made, he is admitted a member of the faculty, upon paying the fees,taking the oaths to the government, and an oath to be faithful in his office.

FACULTY is also used to denote the powers of the human mind, viz. understanding, will, memory, and imagination.

FÆCES, in chemistry, the gross matter, or sediment, that settles at the bottom after distillation, fermentation, &c.

FÆCULA. See GLUTEN.

FAGARA, *iron wood*, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 43d order, dumosæ. The calyx is quadrifid, the corolla tetrapetalous, and the capsule bivalved and monospermous. There are 10 species, all natives of the warm parts of America, rising with woody stems more than 20 feet high. They are propagated by seeds; but in England they must be kept continually in a stove.

FAGG, in the sea language, a term given to the end of those strands which do not go through the tops, when a cable or rope is closed.

FAGONIA, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 14th order, gruinales. The calyx is pentaphyllous; the petals are five, and heart-shaped; the capsule is quinquelocular, ten-valved, with the cells monospermous. There are three species, herbaceous plants of Spain, Crete, and Arabia.

FAGRÆA, a genus of the class and order pentandria monogynia. The calyx is bell-shaped; corolla funnel-shaped; berry two-celled, fleshy, seeds globular; stigma peltate. There is one species, a shrub of Ceylon.

FAGUS, the *beech-tree*, a genus of the polyandria order, in the monœcia class of plants; and in the natural method ranking under the 50th order, amentaceæ. The male calyx is quinquefid, and campanulated: there is no corolla; the stamina are 12; the female calyx is quinquedentated; there is no corolla; there are three styles; the capsule (formerly the calyx) is muricated and quadrivalved; the seeds two in number. There are five species. The most remarkable are,

1. The sylvatica, or beech-tree, rises 60 or 70 feet high, and has a proportionable thickness, branching upward into a fine regular head, with oval serrated leaves, with flowers in globular catkins, succeeded by angular fruit called mast.

2. The castanea, or chesnut-tree, has a large upright trunk growing 40 or 50 feet high, branching regularly round into a fine spreading head, with large spear-shaped acutely serrated leaves, naked on the under side, having flowers in long amentums, succeeded by round prickly fruit, containing two or more nuts.

3. The pumila, dwarf chesnut-tree, or chinkapin, rises eight or ten feet high, with a branching shrubby stem, and oval spear-shaped and acutely serrated leaves, hoary on the under side.

The first species is very easily raised from the mast or seed. "For woods (says Evelyn) the beech must be governed as the oak; in nurseries as the ash: sowing the masts in autumn, or later, even after January, or rather nearer the spring, to preserve them from vermin, which are very great devourers of them. But they are likewise to be planted of young seedlings, to be drawn out of the places where the fruitful trees abound. Millar says, the season for sowing the masts " is any time from October to February, only observing to secure the seeds from vermin when early sowed; which, if carefully done, the sooner they are sown the better after they are fully ripe." Hambury orders a sufficient quantity of masts to be gathered about the middle of September, when they begin to fall: these are to be "spread upon a mat in an airy place six days to dry; and after that you may either proceed to sow them immediately, or you may put them up in bags in order to sow them nearer the spring: as they will keep very well, and there will be less danger of having them destroyed by mice or other vermin, by which kinds of animals they are greatly relished." They must be sown in beds properly prepared, about an inch deep. In the first spring many of the young plants will appear, whilst others will not come up till the spring following. Having stood two years in the seminary,

they should be removed to the nursery, where they may remain till wanted.

The propagation of the second species is also chiefly from seeds. Evelyn says, "Let the nuts be first spread to sweat, then cover them in sand; a month being past, plunge them in water, and reject the swimmers; being dried for 30 days more, sand them again, and expose them to the water-ordeal as before. Being thus treated until the beginning of spring or in November, set them as you would beans; and, as some practise it, drenched for a night or more in new milk; but with half this preparation they need only to be put into the holes with the point upwards, as you plant tulips. If you design to set them in winter or autumn, I counsel you to inter them in their husks, which being every way armed, are a good protection against the mouse, and a providential integument."—"Being come up, they thrive best unremoved, making a great stand for at least two years upon every transplanting; yet if you must alter their station, let it be done about November." Millar cautions us against purchasing foreign nuts that have been kiln-dried, which (he says) is generally done to prevent their sprouting in their passage; therefore he adds, "If they cannot be procured fresh from the tree, it will be much better to use those of the growth of England, which are full as good to sow for timber or beauty as any of the foreign nuts, though their fruit is much smaller." He also recommends preserving them in sand, and proving them in water. In setting these seeds or nuts, he says, "The best way is to make a drill with a hoe (as is commonly practised for kidney-beans), about four inches deep, in which you should place the nuts, at about four inches distance, with their eye uppermost; then draw the earth over them with a rake, and make a second drill at about a foot distance from the former, proceeding as before, allowing three or four rows in each bed. In April (he does not mention the time of sowing) these nuts will appear above ground; you must therefore observe to keep them clear from weeds, especially while young: in these beds they may remain for two years, when you should remove them into a nursery at a wider distance. The best time for transplanting these trees is either in October, or the end of February, but October is the best season: the distance these should have in the nursery is three feet row from row, and one foot in the rows. If these trees have a downright tap-root, it should be cut off, especially if they are intended to be removed again: this will occasion their putting out lateral shoots, and render them less subject to miscarry when they are removed for good. The time generally allowed them in the nursery is three or four years, according to their growth; but the younger they are transplanted the better they will succeed. Young trees of this sort are apt to have crooked stems; but when they are transplanted out, and have room to grow, as they increase in bulk they will grow more upright, and their stems will become straight, as I have frequently observed where there have been great plantations." Hanbury follows Millar almost literally, except that he mentions February as the time of sowing; and recommends that the young plants, a year after they have been planted in the nursery, be cut down to within an inch of the ground; which (he says) "will cause them to shoot vigorously with one strong and straight stem." There is one material objection against sowing chesnuts in drills, which are well known to serve as guides or conductors to the field-mouse, who will run from one end to the other of a drill without letting a single nut escape her: we rather recommend setting them with a dibble, either promiscuously or quincunx, at about six inches distance. Evelyn says, that coppices of chesnuts may be thickened by lowering the tender young shoots; but adds, that "such as spring from the nuts and marrons are best of all." There is a striped-leaved variegation which is continued by budding; and the French are said to graft chesnuts for their fruit; but Millar says, such grafted trees are unfit for timber. The chesnut will thrive upon almost any soil which lies out of the water's way; but dislikes wet moory land.

The method of propagating the dwarf-chesnut is from seeds. These should be planted in drills, in a moist bed of rich garden-mould. If the seeds are good they will come up pretty soon in the spring. After they appear they will require no trouble except keeping them clean from weeds, and watering them in dry weather. They may stand in the seed-bed two years, and be afterwards planted in the nursery ground, at a foot asunder, and two feet distance in the rows; and here when they are got strong plants they will be fit for any purpose.

In stateliness and grandeur of outline the beech excels the oak. Its foliage is peculiarly soft and pleasing to the eye; its branches are numerous and spreading; and its stem grows to a great size. The bark of the beech is remarkably smooth, and of a silvery cast: this, added to the splendour and smoothness of its foliage, gives a striking neatness and delicacy to its general appearance. The beech therefore, standing singly, and suffered to form its own natural head, is highly ornamental: and its leaves varying their hue as the autumn approaches, renders it in this point of view still more desirable. In respect of actual use the beech follows next to the oak and the ash: it is almost as necessary to the cabinet-maker and turner as the oak is to the shipbuilder, or the ash to the plough and cart-wright. Evelyn nevertheless condemns it in pointed and general terms; because "where it lies dry, or wet and dry, it is exceedingly obnoxious to the worm." He adds, however, "but being put ten days in water it will exceedingly resist the worm." The natural soil and situation of the beech are upon dry, chalky, or limestone heights: it grows to a great size upon the hills of Surry and Kent; as also upon the declivities of the Cotswold and Stroudwater hills of Gloucestershire, and flourishes exceedingly upon the bleak banks of the Wye, in Hereford and Monmouth shires; where it is much used in making charcoal. In situations like those, and where it is not already prevalent, the beech, whether as a timber-tree or as an underwood, is an object worthy the planter's attention.

The mast, or seeds, yield a good oil for lamps; and are a very agreeable food to spuirrels, mice, and swine. The fat of swine fed with them, however, is soft, and boils away, unless hardened by some other food. The leaves gathered in autumn, before they are much injured by the frosts, make much better mattrasses than straw or chaff, and last for seven or eight years. The nuts when eaten by the human species, occasion giddiness

and headache; but when well dried and powdered they make wholesome bread. They are sometimes roasted, and substituted for coffee. The poor people in Silesia use the expressed oil instead of butter.

The chesnut-tree sometimes grows to an immense size. The largest in the known world are those which grow upon mount Ætna in Sicily. At Tortworth in Gloucestershire is a chesnut-tree 52 feet round. It is proved to have stood there ever since the year 1150, and was then so remarkable that it was called the great chesnut of Tortworth. It fixes the boundary of the manor, and is probably near 1000 years old. As an ornamental, the chesnut, though unequal to the oak and beech, has a degree of grandeur belonging to it which recommends it strongly to the planter's attention. Its uses have been highly extolled, and it may deserve a considerable share of the praise which has been given it. As a substitute for the oak it is preferable to the elm for door-jambs, window-frames, and some other purposes of the house-carpenter: it is nearly equal to oak itself; but it is very apt to be shaky, and there is a deceitful brittleness in it which renders it unsafe to be used as beams, or in any other situation where an uncertain load is required to be borne. It is universally allowed to be excellant for liquor-casks; as not being liable to shrink, nor to change the colour of the liquor it contains: it is also strongly recommended as an underwood for hop-poles, stakes, &c. Its fruit too is valuable, not only for swine and deer, but as human food: bread is said to have been made of it. Upon the whole, the chesnut, whether in the light of ornament or use, is undoubtedly an object of the planter's notice.

FAILLIS, in heraldry, a French term denoting some failure or fraction in an ordinary, as if it was broken, or a splinter taken from it.

FAIR, a greater kind of market, granted to a town, by privilege, for the more speedy and commodious providing of such things as the place stands in need of.

It is incident to a fair, that persons shall be free from being arrested in it for any other debt or contract than what was contracted in the same, or at least promised to be paid there. Also proclamation is to be made, how long they are to continue; and no person shall sell any goods after the time of the fair is ended, on forfeiture of double the value, one fourth to the prosecutor, and the rest to the king. There is a toll usually paid in fairs, on the sale of things, and for stallage, picage, &c.

Fairs abroad are either free, or charged with toll and imposition. The privileges of free fairs consist chiefly, first, in that all traders, &c. whether natives or foreigners, are allowed to enter the kingdom, and are under the royal protection, exempt from duties, impositions, tolls, &c. Secondly, that merchants, in going or returning, cannot be molested or arrested, or their goods stopped. They are established by letters-patent from the prince. Fairs, particularly free fairs, make a very considerable article in the commerce of Europe, especially that of the Mediteranean, and inland parts of Germany, &c.

The principal British fairs are, 1. Sturbridge-fair, near Cambridge, by far the greatest in Britain, and perhaps in the world. 2. Bristol has two fairs, very near as great as that of Sturbridge. 3. Exeter. 4. West Chester. 5. Edinburgh. 6. Wheyhill; and, 7. Burford-fair, both for sheep. 8. Pancras-fair, in Staffordshire, for saddle-horses. 2. Bartholomew fair, at London, for lean and Welsh black cattle. 10. St. Faith's, in Norfolk, for Scotch runts. 11. Yarmouth fishing-fair for herrings, the only fishing-fair in Great Britain. 12. Ipswich butter-fair. 13. Woodborough-hill, in Dorsetshire, for west-country manufactures, as kerseys, druggets, &c. 14. Two cheese-fairs at Chipping Norton: with innumerable other fairs, besides weekly markets, for all sorts of goods, as well our own as of foreign growth.

Among the principal free fairs in France were those of St. Germains, Lyons, Rheims, Chartres, Rouen, Bourdeaux, Troyes, Bayonne, Dieppe, &c.

The most noted fairs in Germany are those of Francfort, Leipsic, and Nurenburg; not only on account of the great trade, but the vast concourse of princes of the empire, nobility, and people, who come to them from all parts of Germany to partake of the diversions.

FAIRY-CIRCLE, or *ring*, a phenomenon frequent in the fields, &c. supposed by the vulgar to be traced by the fairies in their dances: there are two kinds of it; one of about seven yards in diameter, containing a round bare path, a foot broad, with green grass in the middle of it. The other is of different bigness, encompassed with a circumference of grass greener and fresher than that in the middle. Mess. Jessop and Walker, in the Philosophical Transact. ascribed them to lightning: we have however examined them ourselves, and are convinced they are produced by a kind of fungus which breaks and pulverizes the soil; why this vegetable should put forth its offsets in this kind of circular direction we cannot rightly account. The circles however are seldom complete, and often very irregular.

FAKE, among sailors, signifies one round or circle of a cable or hawser, coiled up out of the way.

FALCATED, something in the form of a sickle: thus the moon is said to be falcated when she appears horned.

FALCO, in ornithology, a genus belonging to the order of accipitres, the characters of which are these: the beak is crooked, and furnished with wax at the base; the head is thick-set with feathers, and the tongue is cloven. The eagle, kite, and hawk, form this genus. There are 32 species, of which the following are the most remarkable.

1. The leucocephalus, bald, or white-headed eagle of Catesby, is ash-coloured, with head and tail white; the iris of the eye is white over which is a prominence covered with a yellow skin; the bill and the cere or wax are yellow, as are likewise the legs and feet; and talons are black. Though it is an eagle of small size, it weighs nine pounds, is strong and full of spirit, preying on lambs, pigs, and fawns. They always make their nests near the sea or great rivers, and usually upon old dead pine or cypress trees, continuing to build annually on the same tree till it falls. Though he is so formidable to all birds, yet he suffers them to build near his royal nest without molestation; particularly the fishing-hawk, herons, &c. which all build on high trees, and in some places are so near one another that they appear like a rookery. The nests are very large and very fetid, owing to the relics of their prey. Lawson says they breed very often, laying again under their callow young, whose warmth hatches the eggs. In Bering's isle they make their nests on the

cliffs near six feet wide and one thick; and lay two eggs in the beginning of July. This species inhabits both Europe and America; but is more common in the latter. Besides flesh, it feeds also on fish. This, however, it does not procure for itself; but sitting in a convenient spot, watches the diving of the fishing-hawk into the water after a fish; which the moment it has seized, the bald eagle follows close after, when the hawk is glad to escape by dropping the fish from his bill; and such is the dexterity of the former, that it often seizes the prey before it can fall to the ground. Catesby says the male and female are much alike.

2. The ossifragus, sea-eagle, or osprey with yellow wax, and half-feathered legs: it is about the size of a peacock; the feathers are white at the base, iron-coloured in the middle, and black at the points; and the legs are yellow. It is found in several parts of Great Britain and Ireland. Mr. Willughby tells us, that there was an eyrie of them in Whinfield-park, Westmoreland; and the bird soaring in the air with a cat in its talons (which Barlow drew from the very fact which he saw in Scotland) is of this kind. The cat's resistance brought both animals to the ground, when Barlow took them up; and afterwards caused the fact to be engraved in the 36th plate of his collection of prints. Turner says, that in his days this bird was too well known in England; for it made horrible destruction among the fish. All authors indeed agree, that it feeds principally on fish, which it takes as they are swimming near the surface, by darting down upon them; not by diving or swimming, as some authors have pretended, who furnish it for that purpose with one webbed foot to swim with, and another divided foot to take its prey. Martin, speaking of what he calls the great eagles of the Western isles, says, that they fasten their talons in the back of the fish, commonly of salmon, which are often above the water, or very near the surface. Those of Greenland will even take a young seal out of the water.

3. The chrysaëtos, or golden eagle (See Pl. LV. Nat. Hist. fig. 191) weighs about twelve pounds, and is in length about three feet, the wings when extended measuring about seven feet four inches. The sight and sense of smelling are very acute: the head and neck are clothed with narrow sharp-pointed feathers, of a deep brown colour bordered with tawny; the hind part of the head in particular is of a bright rust-colour. These birds are very destructive to fawns, lambs, kids, and all kinds of game; particularly in the breeding season, when they bring a vast quantity of prey to their young. Smith, in his History of Kerry, relates that a poor man in that country got a comfortable subsistence for his family, during a summer of famine, out of an eagle's nest, by robbing the eagles of the food which the old one brought; whose attendance he protracted beyond the natural time, by clipping the wings and retarding the flight of the former. It is very unsafe to leave infants in places where eagles frequent, there being instances in Scotland of two being carried off by them; but, fortunately, the theft was discovered in time, and the children were restored unhurt out of the eagle's nests. In order to extirpate these pernicious birds, there is a law in the Orkney isles, which intitles every person that kills an eagle to a hen out of every house in the parish where it was killed. Eagles seem to give the preference to the carcases of dogs and cats. People who make it their business to kill those birds, lay one or other of these carcases by way of bait; and then conceal themselves within gunshot. They fire the instant the eagle alights; for she, that moment, looks about before she begins to prey. Yet, quick as her sight may be, her sense of hearing seems still more exquisite. If hooded crows or ravens happen to be nearer the carrion, and resort to it first, and give a single croak, the eagle is certain instantly to repair to the spot.

Eagles are remarkable for their longevity, and for their power of sustaining a long abstinence from food. Mr. Keysler relates, that an eagle died at Vienna after a confinement of 104 years. This pre-eminent length of days probably gave occasion to the saying of the Psalmist. "Thy youth is renewed like the eagle's." One of this species, which was nine years in the possession of Owen Holland, esq. of Conway, lived 32 years with the gentleman who made him a present of it; but what its age was when the latter received it from Ireland is unknown. The same bird also furnishes us with a proof of the truth of the other remark; having once, through the neglect of servants, endured hunger for 21 days without any sustenance whatever.

4. The fulvus, or white-tailed eagle of Edwards, has the whole plumage of a dusky-brown: the breast marked with triangular spots of white, but which are wanting in the British kind: the tail is white, tipt with black; but in young birds dusky, blotched with white: the legs are covered to the toes with soft rust-coloured feathers. These birds inhabit Hudson's-bay and northern Europe as far as Drontheim. They are found on the highest rocks of the Uralian chain, where it is not covered with wood; but are most frequent on the Siberian, where they make their nests on the loftiest rocks. They are rather inferior in size to the sea-eagle; but are generous, spirited, and docile. The Independant Tartars train them for the chase of hares, foxes, antelopes, and even wolves. This practice is of considerable antiquity; for Marco Polo, the great traveller of 1269, observed and admired the diversion of the great cham of Tartary, who had several eagles which were applied to the purposes we have here described. The Tartars also esteem the feathers of the tail as the best they have for pluming their arrows. This species is frequent in Scotland; where it is called the black eagle, from the dark colour of its plumage. It is very destructive to deer, which it will seize between the horns; and by incessantly beating it about the eyes with its wings, soon makes a prey of the harassed animal. The eagles in the isle of Rum have nearly extirpated the stags that used to abound there. They generally build in cliffs or rocks near the deer-forests; and make great havock not only among them, but also among the white hares and ptarmigans. Mr. Willughby gives the following curious account of the nest of this species. "In the year of our Lord 1668, in the woodlands near the river Darwent, in the peak of Derbyshire, was found an eagle's nest made of great sticks, resting one end on the edge of a rock, the other on two birch-trees; upon which was a layer of rushes, and over them a layer of heath, and upon the heath rushes again; upon which lay one young one and an addled egg; and by them a lamb, a hare, and three heathpoults. The nest

was about two yards square, and had no hollow in it. The young eagle was as black as a hobby, of the shape of a gos-hawk, almost of the weight of a goose, rough-footed, or feathered down to the foot: having a white ring about the tail.

5. the cyaneus, or hen-harrier, with white wax, yellow legs, a whitish-blue body, and a white ring round the eyes and throat. It is the blue hawk of Edwards, and is a native of Europe and Africa. These birds are extremely destructive to young poultry and to the feathered game: they fly near the ground, skimming the surface in search of prey. They breed on the ground, and are never observed to settle on trees.

6. The albicilla, or cinereous eagle, is inferior in size to the golden eagle; the head and neck are of a pale ash-colour; the body and wings cinereous, clouded with brown; the quill feathers very dark; the tail white; the legs feathered but little below the knees, and of a very bright yellow. The male is of a darker colour than the female. The bill of this species is rather straighter than is usual in the eagle, which seems to have induced Linnæus to place it among the vultures. But Mr. Pennant observes, that it can have no title to be ranked with that genus, the characteristical mark of which is, that the head and neck are either quite bare, or only covered with down; whereas this bird is wholly feathered. This species is in size equal to the black eagle, and inhabits Europe as high as Iceland and Lapmark. It is common in Greenland, but does not extend to America; or, according to Mr. Pennant, if it does, it varies into the white-headed eagle, to which it has great affinity particularly on its feeding much on fish: the Danes therefore call it fiskéorn. It is common in the south of Russia, and about the Volga, as far as trees will grow; but it is very scarce in Siberia. It inhabits Greenland the whole year, sitting on the rocks with flagging wing, and flies slowly. It makes its nest on the lofty cliffs, with twigs, lining the middle with mosses and feathers; lays two eggs; and sits in the latter part of May or beginning of June. These birds prey on young seals, which they seize as they are floating on the water; but frequently, by fixing their talons in an old one, they are overmatched, and drawn down to the bottom, screaming horribly. They feed also on fish, especially the lumpfish, and a sort of trout; on ptarmigans, auks, and eider ducks. They sit on the top of rocks, attentive to the motion of the diving birds, and with quick eyes observe their course by the bubbles which rise to the surface of the water, and catch the fowls as they rise for breath. The Greenlanders use their skins for clothing next to their bodies; eat the flesh; and keep the bill and feet for amulets. They kill them with the bow; or take them in nets placed in the snow properly baited; or tempt them by the fat of seals, which the eagles eat to an excess which occasions such a torpidity as to make them an easy prey. They are common in Scotland and the Orkneys, where they feed on fish, as well as on land-animals.

7. The maculatus, or the crying eagle, with a dusky bill and yellow cere; the colour of the plumage is a ferruginous brown; the coverts of the wings and scapulars are elegantly varied with oval white spots; the primaries dusky, the ends of the greater, white; the breast and belly are of a deeper colour than the rest of the plumage, streaked downwards with dull yellow; the tail is dark brown, tipt with dirty white; the legs are feathered to the feet, which are yellow. The length of the bird is two feet. This species is found in many parts of Europe, but not in Scandinavia: is frequent in Russia and Siberia; and extends even to Kamschatka. It is less generous and spirited than other eagles, and is perpetually making a plaintive noise; from which it was styled by the ancients planga et clanga; and anataria, from its preying on ducks, which Pliny describes with great elegance. The Arabs used to train it for the chase: but its quarry was cranes and other birds, the more generous eagle being flown at antelopes and other quadrupeds. This species was itself an object of diversion, and made the game of even so small a bird as the sparrowhawk; which would pursue it with great eagerness, soar above, and then fall on it, and fastening with its talons, keep beating it about the head with its wings, till they both fell together to the ground. This sir John Chardin has seen practised about Tauris.

8. The milvus, or kite, is a native of Europe, Asia, and Africa. This species generally breeds in large forests or woody mountainous countries. Its nest is composed of sticks, lined with several odd materials, such as rags, bits of flannel, rope, and paper. It lays two, or at most three, eggs; which, like other birds of prey, are much rounded and blunt at the smaller end. They are white spotted with dirty yellow. Its motion in the air distinguishes it from all other birds, being so smooth and even that it is scarcely perceptible. Sometimes it will remain quite motionless for a considerable space; at others glide through the sky without the least apparent action of its wings; thence deriving the old name of glead, or glede, from the Saxon glida. They inhabit the north of Europe, as high as Jalsberg, in the very south of Norway; but do not extend farther. They quit Sweden in flocks at the approach of winter, and return in spring. Some of them winter about Astrakan, in lat. 46, 30: but the far greater part are supposed to retire into Egypt, being seen in September passing by Constantinople in their way from the north; and again in April returning to Europe, to shun the great heats of the East. They are observed in vast numbers about Cairo, where they are extremely tame, and feed even on dates, probably for want of other food. They also breed there; so that, contrary to the nature of other rapacious birds, they increase and multiply twice in the year; once in the mild winters of Egypt, and a second time in the summers of the north. It makes its appearance in Greece in the spring; and in the early ages, says Aristophanes, "it governed that country; and men fell on their knees when they were first blessed with the sight of it, because it announced the flight of winter, and told them to begin to shear their vernal fleeces." In Britain they are found the whole year. Lord Bacon observes, that when kites fly high, it portends fair and dry weather. See Plate LV. Nat. Hist. fig. 197.

9. The gentilis, or gentil falcon, inhabits the north of Scotland, and was in high esteem as a bold and spirited bird in the days of falconry. It makes its nest in rocks: it is larger than the gos-hawk; the head of a light rust-colour, with oblong black spots; the whole

under side from chin to tail white, tinged with yellow; the back of a brown colour; the tail barred with four or five bars of black, and as many of ash-colour; the very tips of all the tail feathers white.

10. The subbuteo, or hobby, was used like the kestrel in the humbler kind of falconry; particularly in what was called daring of larks: the hawk was cast off; the larks, aware of their most inveterate enemy, were fixed to the ground for fear; by which means they became a ready prey to the fowler, who drew a net over them. The back of the bird is brown: the nape of the neck white: and the belly pale, with oblong brown spots. It is a bird of passage; but breeds in Britain, and migrates in October.

11. The buteo, or buzzard, is the most common of the hawk kind in England. It breeds in large woods; and usually builds on an old crow's nest, which it enlarges, and lines with wool and other soft materials. It lays two or three eggs, which are sometimes perfectly white, sometimes spotted with yellow. The cock-buzzard will hatch and bring up the young if the hen is killed. The young keep company with the old ones for some little time after they quit the nest; which is not usual with other birds of prey, who always drive away their brood as soon as they can fly. The buzzard is very sluggish and inactive, and is much less in motion than any other hawks; remaining perched on the same bough for the greatest part of the day, and dwelling at most times near the same place. It feeds on birds, rabbits, moles, and mice; it will also eat frogs, earthworms, and insects. This bird is subject to some variety in its colour. Some have the breast and belly of a brown colour, and are only marked across the craw with a large white crescent; but usually the breast is of a yellowish white, spotted with oblong rust-coloured spots, pointing downwards, the back of the head, neck, and coverts of the wings, are of a deep brown, edged with a pale rust-colour: the middle of the back covered only with thick white down. The tail is barred with black and ash-colour, and sometimes ferruginous.

12. The tinnunculus, or kestrel, breeds in the hollows of trees, in the holes of high rocks, towers, and ruined buildings. It feeds on field-mice, small birds, and insects: which it will discover at a great distance. This is the hawk that we so frequently see in the air as fixed in one place; and, as it were, fanning with its wings; at which time it is watching for its prey. When falconry was in use in Great Britain, this bird was trained for catching of small birds and young partridges. It is easily distinguished from all other hawks by its colours. The crown of the head and the greater part of the tail are of a light grey; the back and coverts of the wing of a brick-red, elegantly spotted with black; the whole under side of the bird of a pale rust-colour spotted with black.

13. The sufflator, with yellowish wax and legs; the body is of a brownish-white colour; and the covers of the eyes are bony. He has a fleshy lobe between the nostrils; which, when angry or terrified, he inflates till his head becomes as big as his whole body. He is a native of Surinam.

14. The cachinnans, or laughing hawk, has yellowish legs and wax, and white eyebrows; the body is variegated with brown and white: and has a black ring round the top of the head. It makes a laughing kind of noise when it observes any person, and is a native of America.

15. The Columbarius, or pigeon-hawk of Catesby, weighs about six ounces. The bill is black at the point, and whitish at the base: the iris of the eye is yellow; the base of the upper mandible is covered with a yellow cere of wax: all the upper part of the body, wings, and tail, are brown. The anterior vanes of the quill-feathers have large red spots. The tail is marked with large regular transverse white lines; the throat, breast, and belly, are white, mixed with brown; the small feathers that cover the thighs reach within half an inch of the feet, and are white, with a tincture of red, beset with long spots of brown; the legs and feet are yellow. It inhabits America, from Hudson's-bay as low as South Carolina. In the last it attains to a larger size. In Hudson's-bay it appears in May on the banks of the river Severn, breeds, and retires south in autumn. It feeds on small birds; and, on the approach of any person, flies in circles, and makes a great shrieking. It forms its nest in a rock, or some hollow tree, with sticks and grass; and lines it with feathers; and lays from two to four eggs, white spotted with red. In Carolina it preys on pigeons, and the young of the wild turkeys.

16. The furcatus, or swallow-tailed hawk, has a black bill, less hooked than usual with rapacious birds: the eyes are large and black, and with a red iris: the head, neck, breast, and belly, are white; the upper part of the back and wings a dark purple; but more dusky towards the lower parts, with a tincture of green. The wings are long in proportion to the body, and when extended, measure four feet. The tail is dark purple mixed with green, and remarkably forked. This most elegant species inhabits the southern parts of North America only during summer. Like swallows, they feed chiefly flying; for they are much on wing, and prey on various sorts of insects. They also feed on lizards and serpents; and will kill the largest of the regions it frequents with the utmost ease. They quit North America before winter, and are supposed to retreat to Peru.

17. Haliætus, the fishing-hawk of Catesby, sometimes called the osprey, weighs 3 pounds and a quarter; it measures, from one end of the wing to the other, five feet and a half. The bill is black, with a blue cere or wax; the iris of the eye is yellow, and the crown of the head brown, with a mixture of white feathers; from each eye, backwards, runs a brown stripe: the back, wings, and tail, are of a dark brown; the throat, neck, and belly, white; the legs and feet are rough and scaly, and of a pale blue colour; the talons are black, and nearly of an equal size: the feathers of the thigh are short, and adhere close to them, contrary to others of the hawk kind, which nature seems to have designed for the more easily penetrating the water. Notwithstanding this bird is so persecuted by the bald eagle, yet it always keeps near its haunts. It is a species of vast quickness of sight; and will see a fish near the surface from a great distance, descend with prodigious rapidity, and carry the prey with an exulting scream high into the air. The eagle hears the note; and instantly attacks the fishing-

hawk: who drops the fish, which the former catches before it can reach the ground or water. The lower parts of the rivers and creeks near the sea, in America, abound with these eagles and hawks, where such diverting contests are often seen. It sometimes happens that this bird perishes in taking its prey, for if it chances to fix its talons in an overgrown fish it is drawn under water before it can disengage itself, and is drowned. See Plate LV. Nat. Hist. fig. 194.

18. The gyrfalco, or Iceland falcon, has a strong bill, much hooked, the upper mandible sharply angulated on the lower edges, with a bluish wax: the head is of a very pale rust-colour, streaked downwards with dusky lines: the neck, breast, and belly, are white, marked with cordated spots; the thighs white, crossed with short bars of deep brown: the back and coverts of the wings are dusky, spotted, and edged with white; the exterior webs of the primaries dusky mottled with reddish-white, the inner barred with white; the feathers of the tail are crossed with 14 or more narrow bars of dusky and white, the dusky bars regularly opposing those of white: the wings, when closed, reach almost to the end of the train: the legs are strong and yellow. The length of the wing, from the pinion to the tip, is sixteen inches. This species is an inhabitant of Iceland, and is the most esteemed of any for the sport of falconry.

19. The fuscus, or Greenland eagle, has dusky irides; lead-coloured wax and feet; brown crown, marked with irregular oblong white spots; whitish forehead; blackish cheeks; the hind part of the head and throat white; breast and belly of a yellowish white, striped downwards with dusky streaks; the back dusky, tinged with blue, the ends of the feathers lightest, and sprinkled over with a few white spots, especially towards the rump; the wings of the same colours, variegated beneath with white and black; the upper part of the tail dusky, crossed very faintly with paler bars, the under side whitish. It inhabits all parts of Greenland, from the remotest hills to those which impend over the sea. They are even seen on the islands of ice remote from the shore. They retire in the breeding-season to the farthest part of the country, and return in autumn with their young. They breed in the same manner as the cinereous eagle, but in more distant places; and lay from three to five eggs. The tail of the young is black, with great brown spots on the exterior webs. They prey on ptarmigans, auks, and all the small birds of the country. They have frequent disputes with the raven, but seldom come off victors; for the raven will, on being attacked, fling itself on its back; and either by defending itself with its claws, or by calling, with its croaking, numbers of others to its help, oblige the falcon to retire. The Greenlanders use the skin, among others, for their inner garments; the wings for brushes; the feet for amulets; but seldom eat the flesh, unless compelled by hunger.

20. The candicans, or white gyrfalcon of Pennant, has the wax and bill bluish, the latter greatly hooked; the eye dark-blue; the throat of a pure white; the whole body, wings, and tail, of the same colour, most elegantly marked with dusky bars, lines, or spots, leaving the white the far prevailing colour. There are instances, but rare, of its being found entirely white. In some, the whole tail is crossed by remote bars of black or brown; in others, they appear only very faintly on the middle feathers: the feathers of the thighs are very long and unspotted; the legs strong, and of a light blue. Its weight is 45 ounces troy; length near two feet, extent four feet two. This species has the same manners and haunts with the former. It is very frequent in Iceland; is found in Lapmark and Norway, and rarely in the Orkneys and North Britain. In Asia, it dwells in the highest points of the Uralian and other Siberian mountains, and dares the coldest climates throughout the year. It is kept in the latitude of Petersburgh, uninjured in the open air during the severest winters. This species is pre-eminent in courage as well as beauty, and is the terror of the other hawks. It was flown at all kinds of fowl, how great soever they were: but its chief game used to be herons and cranes.

The last three species are in high esteem for sport. They are reserved for the kings of Denmark; who send their falconer with two attendants annually into Iceland to purchase them. They were caught by the natives, a certain number of whom in every district are licensed for that purpose. The Iceland falcons will last ten or twelve years; whereas those of Norway, and other countries, seldom are fit for sport after two or three years. Yet the Norwegian hawks were in old times in great repute in this kingdom, and even thought bribes worthy of a king.

21. The apivorus, with black wax, yellow legs half-naked, the head of an ash-colour, and having an ash-coloured stripe on the tail, which is white at the end. It is the honey-buzzard of Ray, and had that name from the combs of bees or wasps being found in its nest. It is a native of Europe, and feeds on mice, lizards, frogs, bees, &c. It runs very swiftly, like a hen.

22. The æruginosus, or moor-buzzard, with greenish wax, a greyish body, the top of the head, nape of the neck, and legs, yellowish; it is a native of Europe, and frequents moors, marshy places, and heaths: it never soars like other hawks; but commonly sits on the ground, or on small bushes. It makes its nest in the midst of a tuft of grass, or rushes. It is a very fierce and voracious bird; and is a great destroyer of rabbits, young wild ducks, and other water-fowl. It also preys, like the fishing-hawk, on fish.

23. The palumbarius, with black wax edged with yellow, yellow legs, a brown body, the prime feathers of the tail marked with pale streaks, and the eyebrows white. It is the gos-hawk of Ray; and was formerly in high esteem among falconers, being flown at cranes, geese, pheasants, and partridges. It breeds in Scotland, and builds its nest in trees. It is destructive to game, and dashes through the woods after its quarry with vast impetuosity; but if it cannot catch the object of its pursuit almost immediately, desists, and perches on a bough till some new game presents itself. This species is common in Muscovy and Siberia. They extend to the river Amur; and are used by the emperor of China in his sporting progresses, attended by his grand falconer, and 1000 of the subordinate. Every bird has a silver plate fastened to its foot, with the name of the falconer who has the charge of it; that, in case it should be lost, it might be brought to the proper person: but if he could not be found, the bird is delivered to another officer,

called the guardian of lost birds; who keeps it till it is demanded by the falconer to whom it belonged. That this great officer may the more readily be found among the army hunters who attend the emperor, he erects a standard in the most conspicuous place.

24. The nisus, or sparrowhawk, with green wax, yellow legs, a white belly undulated with grey, and the tail marked with blackish belts. This is the most pernicious hawk we have, and makes great havock among pigeons as well as partridges. It builds in hollow trees, in old nests of crows, large ruins, and high rocks: it lays four white eggs, encircled near the blunter end with red specks.

25. The minutus, with white wax, yellow legs, and the body white underneath. It is the least hawk of Brisson, being about the size of a thrush: and is found on the island of Melita.

Besides these we may mention the litho-falco, or stone falcon, which inhabits many parts of Europe, and is about a foot long; the bill blueish-ash; irids yellow; two middle tail-feathers uniform, the rest barred with brown: the gallicus or French eagle, so called from its being found chiefly in France, about two feet long, feeds on rats, mice, and frogs; it builds its nest mostly on the ground; the irids yellow; tail-feathers white with brown transverse stripes, brown at the tips and edges; claws grey: the lacer inhabits Europe, Tartary in Asia, and many parts of North America; it is two feet long, patient of cold; used in hunting the white heron: the head pale brown; wing-coverts and primary quill feathers with transverse white lines; tail brown, with oval transverse red spots on the sides; legs feathered to the toes: and the magnirostris, or great billed falcon, found in Cayenne a little larger than the sparrowhawk; legs shorter; bill longer, thicker, black; irids orange; feathers above and on the breast brown edged with rusty; claws black. See Plate LV. Nat. Hist. figs. 192, 193, 195, and 196.

There are some other species distinguished by ornithologists. Among these are two described by Mr. Bruce; of which one deserves particular notice, as being not only the largest of the eagle kind, but supposed to be the largest bird that flies. He calls it the golden eagle; by the natives it is vulgarly called abon duchn, or father long beard.

FALCONRY, the exercise of taking wild-fowl by means of hawks. There are only two countries in the world where we have any evidence that the exercise of hawking was very anciently in vogue. These are Thrace and Britain. In the former it was pursued merely as the diversion of a particular district, if we may believe Pliny (b. x. 8.), whose account is rendered obscure by the darkness of his own ideas of the matter. The primæval Britons, with a fondness for the exercise of hunting, had also a taste for that of hawking; and every chief among them maintained a considerable number of birds for that sport. To the Romans this diversion was scarcely known in the days of Vespasian; yet it was introduced immediately afterwards. Most probably they adopted it from the Britons; but we certainly know that they greatly improved it by the introduction of spaniels into the island. In this state it appears among the Roman Britons in the sixth century. Gildas, in a remarkable passage in his first epistle, speaks of Maglocunus, on his relinquishing the sphere of ambition, and taking refuge in a monastery; and proverbially compares him to a dove, that hastens away at the noisy approach of the dogs, and with various turns and windings takes her flight from the talons of the hawk.

In after-times, hawking was the principal amusement of the English: a person of rank scarcely stirred out without his hawk on his hand; which, in old paintings, is almost the criterion of nobility. Harold, afterwards king of England, when he went on a most important embassy into Normandy, is painted embarking with a bird on his finger, and a dog under his arm: and in an ancient picture of the nuptials of Henry VI. a nobleman is represented in much the same manner; for in those days, "it was thought sufficient for noblemen to winde their horn, and to carry their hawk fair, and leave study and learning to the children of mean people."

The expense was great that sometimes attended this sport. In the reign of James I. sir Thomas Monson is said to have given 1000*l.* for a cast of hawks; we are not then to wonder at the rigour of the laws that tended to preserve a pleasure which was carried to such an extravagant pitch. In the 34th of Edward III. it was made felony to steal a hawk; to take its eggs, even in a person's own ground, was punishable with imprisonment for a year and a day, besides a fine at the king's pleasure: in queen Elizabeth's reign, the imprisonment was reduced to three months; but the offender was to find security for his good behaviour for seven years, or lie in prison till he did.

The falcons or hawks that were in use in these kingdoms are now found to breed in Wales, and in North Britain and its isles. The peregrine-falcon inhabits the rocks of Caernarvonshire. The same species, with the gyr-falcon, the gentil, and the gos-hawk, are found in Scotland, and the latter in Ireland.

We may here take notice, that the Norwegian breed was, in old times, in high esteem in England: they were thought bribes worthy of a king. Jeoffrey Fitzpierre gave two good Norway hawks to king John, to obtain for his friend the liberty of exporting 100 cwt. of cheese; and Nicholas the Dane was to give the king a hawk every time he came into England, that he might have free liberty to traffic throughout the king's dominions.

They were also made the tenures that some of the nobility held their estates by, from the crown. Thus sir John Stanley had a grant of the isle of Man from Henry IV. to be held of the king, his heirs, and successors, by homage and the service of two falcons, payable on the day of his or their coronation. And Philip de Hastang held his manor of Combertoun, in Cambridgeshire, by the service of keeping the king's falcons.

Falconry, though an exercise now much disused in comparison with what it anciently was, does yet furnish a great variety of significant terms, which still obtain in our language. Thus, the parts of a hawk have their proper names. The legs from the thigh to the foot, are called *arms;* the toes the *petty singles;* the claws the *pounces.* The wings are called the *sails;* the long feathers the *beams;* the two longest, the *principal feathers;* those next, the *flags.* The tail is called the *train;* the breast-feathers the *mails;* those behind the thigh the *pendant feathers.* When the feathers are not yet full-grown she is said to be *unsummed;* when they are complete, she

is *summed:* the craw, or crop, is called the *gorge;* the pipe next the fandament, where the fæces are drawn down, is called the *pannel:* the slimy substance lying in the pannel is called the *glut:* the upper and crooked part of the bill is called the *beak;* the nether part, the *clap;* the yellow part between the beak and the eyes, the *sear* or *sere:* the two small holes therein, the *nares.*

As to her furniture: the leathers with bells buttoned on her legs, are called *bewits.* The leathern thong, whereby the falconer holds the hawk, is called the *lease* or *lash;* the little straps, by which the lease is fastened to the legs, *jesses;* and a line or packthread fastened to the lease, in disciplining her, a *creance.* A cover for her head, to keep her in the dark, is called a *hood;* a large wide hood, open behind, to be worn at first, is called a *rufter-hood:* to draw the strings, that the hood may be in readiness to be pulled off, is called *unstriking the hood.* The blinding a hawk just taken, by running a thread through her eyelids, and thus drawing them over the eyes, to prepare her for being hooded, is called *seeling.* A figure or resemblance of a fowl, made of leather and feathers, is called a *lure.* Her resting-place, when off the falconer's hand, is called the *perch.* The place where her meat is laid, is called the *hack;* and that wherein she is set while her feathers fall and come again, the *mew.*

Something given a hawk to cleanse and purge her gorge, is called *casting.* Small feathers given her to make her cast, are called *plumage.* Gravel given her to help to bring down her stomach is called *rangle.* Her throwing up filth from the gorge after casting is called *gleaming.* The purging of her grease, &c. *enseaming.* Her being tuffed is called *gurgiting.* The inserting a feather in her wing in lieu of a broken one is called *imping.* The giving her a leg, wing, or pinion of a fowl to pull at is called *tiring.* The neck of a bird the hawk preys on is called the *inke.* What the hawk leaves of her prey is called the *pill* or *pelf.*

There are also proper terms used for several actions. When she flutters with her wings, as if striving to get away, either from the perch or fist, she is said to *bate.* When, standing too near, they fight with each other, it is called *crabbing.* When the young ones quiver, and shake their wings in obedience to the elder, it is called *cowring.* When she wipes her beak after feeding, she is said to *seak.* When she sleeps, she is said to *jouk.* From the time of exchanging her coat till she turn white again, is called her *intermewing.* Treading is called *cawking.* When she stretches one of her wings after her legs, and then the other, it is called *mantling.* Her dung is called *muting;* when she mutes a good way from her, she is said to *slice;* when she does it directly down, instead of yerking backwards, she is said to *slime;* and when if it be in drops, it is called *dropping.* When she sneezes it is called *sniting.* When she raises and shakes herself she is said to *rouze.* When, after mantling, she crosses her wings together over her back, she is said to *warble.*

When a hawk seizes she is said to *bind.* When, after seizing, she pulls off the feathers she is said to *plume.* When she raises a fowl aloft, and at length descends with it to the ground, it is called *trussing.* When, being aloft, she descends to strike her prey, it is called *stooping.* When she flies out too far from game she is said to *rake.* When, forsaking her proper game, she flies at pyes, crows, &c. that chance to cross her, it is called the *check.* When, missing the fowl, she betakes herself to the next check, she is said to *fly on head.* The fowl or game she flies at is called the *quarry.* The dead body of a fowl killed by the hawk is called a *pelt.* When she flies away with the quarry she is said to *carry.* When in stooping she turns two or three times on the wing, to recover herself ere she seizes, it is called *cancelicring.* When she hits the prey, yet does not truss it, it is called *ruff.* The making a hawk tame and gentle is called *reclaiming.* The bringing her to endure company, *manning* her. An old staunch hawk, used to fly and set example to a young one, is called a *make-hawk.*

The reclaiming, manning, and bringing up a hawk to the sport, is not easy to be brought to any precise set of rules. It consists in a number of little practices and observances, calculated to familiarize the falconer to his bird, to procure the love of it, &c.

When your hawk comes readily to the lure, a large pair of luring bells are to be put upon her; and the more giddy-headed and apt to rake out your hawk is, the larger must the bells be. Having done this, and she being sharpset, ride out in a fair morning, into some large field unencumbered with trees or wood, with your hawk on your hand; then having loosened her hood, whistle softly to provoke her to fly; unhood her, and let her fly with her head into the wind; for by that means she will be the better able to get upon the wing, and will naturally climb upwards, flying a circle. After she has flown three or four turns, then lure her with your voice, casting the lure about your head, having first tied a pullet to it; and if your falcon come in and approach near you, cast out the lure into the wind, and if she stoop to it reward her.

You will often find, that when she flies from the first, she will take stand on the ground: this is a fault which is very common with soar-falcons. To remedy this, fright her up with your wand; and when you have forced her to take a turn or two, take her down to the lure and feed her. But if this does not do, then you must have in readiness a duck sealed, so that she may see no way but backwards, and that will make her mount the higher. Hold this duck in your hand, by one of the wings near the body, then lure with the voice, to make the falcon turn her head; and when she is at a reasonable pitch, cast your duck up just under her; when, if she strikes, stoops, or trusses the duck, permit her to kill it, and reward her by giving her a reasonable gorge. After you have practised this two or three times, your hawk will leave the stand, and, delighted to be on the wing, will be very obedient.

It is not covenient, for the first or second time, to show your hawk a large fowl; for it frequently happens, that they escape from the hawk, and she, not recovering them, rakes after them: this gives the falconer trouble, and frequently occasions the loss of the hawk. But if she happens to pursue a fowl, and being unable to recover it, gives it over, and comes in again directly, then cast out a sealed duck: and if she stoops and trusses it across the wings, permit her to take her pleasure, rewarding her also with the heart, brains, tongue, and liver. But if you have not a quick duck, take her down with a dry lure, and let her plume a pullet and feed up-

on it. By this means a hawk will learn to give over a fowl that rakes out, and, on hearing the falconer's lure, will make back again, and know the better how to hold in the head.

Some hawks have a disdainful coyness, proceeding from their being high-fed; such a hawk must not be rewarded though she should kill: but you may give her leave to plume a little; and then taking a sheep's heart cold, or the leg of a pullet, when the hawk is busy pluming, let either of them be conveyed into the body of the fowl, that it may savour of it; and when the hawk has eaten the heart, brains, and tongue of the fowl, take out what is inclosed, call her to your fist, and feed her with it; afterwards give her some of the feathers of the fowl's neck, to scour her, and make her cast.

If your hawk is a stately high-flying one, she ought not to take more than one flight in a morning; and if she is made for the river let her not fly more than twice: when she is at the highest, take her down with your lure; and when she has plumed and broken the fowl a little, feed her, by which means you will keep her a high-flier, and fond of the lure.

FALDFEY, or FALDFEE, a rent or fee paid by some customary tenants, for liberty to fold their sheep on their own lands.

FALL, is the name of a measure of length used in Scotland, and containing six ells of that country.

FALL, in the sea language, that part of the rope of a tackle, which is hauled upon. Also when a ship is under sail, and keeps not so near the wind as she should do, they say she falls off; or when a ship is not flush, but has risings of some parts of her decks more than others, it is called falls.

FALLOPIAN TUBES. See ANATOMY.

FALLOWING *of land*. See HUSBANDRY.

FALSE, in music, an epithet applied to theorists to certain chords, called false, because they do not contain all the intervals appertaining to those chords in their perfect state: as a fifth, consisting of only six semitonic degrees, is denominated a false fifth. Those intonations of the voice which do not truly express the intended interval are also called false, as well as all ill-adjusted combinations; and those strings, pipes, and other sonorous bodies, which, from the ill-disposition of their parts, cannot be accurately tuned. Certain closes are likewise termed false, in contradistinction to the full or final close. See CLOSE.

FALSETTO, (Ital.) that species of voice in a man, the compass of which lies above his natural voice, and is produced by artificial constraint.

FALSIFYING, in law, the proving a thing to be false. The falsifying a record, is where a person purchases land of another, who is afterwards outlawed for felony; in this case, he may falsify the record as to the time when the felony is supposed to have been committed, and also as to the point of the offence. But in the case where a person is found guilty by verdict, such purchaser shall only falsify the time. To falsify a recovery may be done by the issue in tail, where it is suffered by a tenant for life.

FALSO RETURNO BREVIUM, a writ that lies against a sheriff for false returning of writs he had got to execute.

FALSO BORDONE, in music, a term applied in the early days of descant to such counterpoint as had either a drone bass, or some part constantly moving in the same interval with it.

FALX, in anatomy, a process of the dura mater placed between the two hemispheres of the brain, and resembling a reaper's sickle.

FAMILIARS *of the inquisition*, are people that assist in the apprehending of such persons as are accused, and carrying them to prison; upon which occasion, the unhappy person is surrounded by such a number of these officious gentlemen, that there is no possibility of escaping out of their hands. As a reward of this base employ, the familiars are allowed to commit the most atrocious actions, to debauch, assassinate, and kill, with impunity.

FAN, an instrument used in husbandry. See HUSBANDRY.

FANDANGO, a dance much practised in Spain, and of which the natives of that country are particularly fond. Its air is lively, and much resembles the English hornpipe.

FANTASIA, (Ital.) the name generally given to a species of composition, supposed to be struck off in the heat of imagination, and in which the composer is allowed to give free range to his ideas, and to disregard those restrictions by which other productions are confined. Some writers limit the application of this term to certain extemporaneous flights of fancy; and say, that the moment they are written, or repeated, they cease to be fantasias. This, they add, forms the only distinction between the fantasia and the capricio. The capricio, though wild, is the result of premeditation, committed to paper, and becomes permanent: but the fantasia is an impromptu, transitive, and evanescent; exists but while it is executing, and when finished is no more. Fantasias being, however, daily written and published, it is evident in which of the above senses the word is now to be understood.

FARINA FŒCUNDANS, among botanists, the impregnating meal or dust on the apices or antheræ of flowers; which being received into the pistil, or seed-vessel of plants, fecundates the rudiments of the seeds in the ovary, which otherwise would decay and come to nothing.

The manner of gathering the farina of plants for microscopical observation is this: Gather the flowers in the midst of a dry sun-shiny day when the dew is perfectly off; then gently shake off the farina, or lightly brush it off with a soft hair-pencil, upon a piece of white paper; then take a single talc of isinglass between the nippers, and, breathing on it, apply it instantly to the farina, and the moisture of the breath will make that light powder stick to it. If too great a quantity is found adhering to the talc, blow a little of it off; and if there is too little, breathe upon it again, and take up more. When this is done, put the talc into the hole of a slider; and applying it to the microscope, see whether the little grains are laid as you desire, and if they are, cover them up with another talc, and fix the ring, but care must be taken that the talcs do not press upon the farinæ in such a manner as to alter the form.

FARLEY, or FARLIEU, money paid by tenants in the west of England, in lieu of a heriot. See HERIOT.

FARM, or FERM, signifies the chief messuage in a village, or any large messuage on which land belongs, meadow, pasture, wood, common, &c. and which has been used to let for term of life or years, under a certain yearly rent payable by the tenant for the same. See HUSBANDRY.

FARMER, among miners, signifies the lord of the field, or the person who farms the lot and cope of the king.

FARRIERY, the art and profession of the farrier, which have comprehended, from the earliest even to the present period, the medical and surgical care of the horse, as well as that of manufacturing and fitting him with shoes. These men, as labourers of iron, were originally termed ferrers, or ferriers, from the Latin word *ferrum*, iron, and their craft ferriery; which word has since, either by a very usual corruption or improvement of language, been changed to farriery. This term remains yet in general use to its fullest extent, and not inaptly; since notwithstanding the laudible attempts of many enlightened men at various periods, our blacksmiths form a very large majority of horse surgeons and physicians. Nor is such defect peculiar to this country, but prevails in an equal degree throughout Europe; even in Italy and France, countries which preceded us many centuries in veterinary science, and from which indeed we have derived its elements.

On the establishment of a college, in England, in 1790, for the instruction of pupils in animal medicine and surgery, under a French professor, (Saintbel) was imported also from France the term *veterinary*, and the veterinary art has been since substituted for farriery by practitioners of liberal education. The supposed derivation of the term veterinary is from the participle *vectum*, of the Latin verb *veho*, to carry; *quasi* vecterinary, thence applied to the care of animals which carry, or beasts of burden. The change to veterinary was easy and in course; and if, according to the opinions of some, we ought to revert to the radical orthography, and write ferriery instead of farriery, a parity of reasoning, and desire of close adherence to the root, would induce us to retain the *c*, and pronounce the word vecterinary. It is easy to conceive what revolutions in language such attempts would occasion if generally put in practice; but by no means easy to discover the utility of a capricious and partial adoption of such changes in particular words.

The term veterinary was originally used by the Latins, (Vegetius) and has a more extensive import than our farriery, which relates to the horse solely; whereas the former comprehends the care, both in health and in a state of disease, of all those animals domesticated for the laborious service or food of man. In a history of the general science those branches may, however, be properly considered together.

From the manifest great consequence of the services of the domestic animals to man, in a state of civilization, they have, from a very remote period of antiquity, been the objects of his study and attention, both as to their ordinary management, and that which was requisite for them in a state of disease: for the latter a peculiar system was formed, including a meteria medica and general mode of treatment considerably distinct from those in use with human patients. Of the authors of this system, whether Greek or Roman, nothing worth notice has been handed down beyond an occasional citation of names, to be found in Columella the Roman writer, who lived in the reign of Tiberius, and treated at large on the general management of cattle; and in Vegetius Renatus, who lived two centuries afterwards, and wrote more professedly on animal diseases. Both these authors have treated their subject in elegant and classical Latin; and the latter most particularly has urged, in very eloquent and forcible language, the necessity of a liberal cultivation of the veterinary art, as well on the score of profit as of humanity. It ought to be remembered, however, that neither of these authors had the benefit of any professional acquaintance with medicine or surgery, obscure and imperfect as were those sciences in their days; and that no ancient treatise on the diseases of animals, written by a professional man, has descended to posterity. Nor is this in the smallest degree to be regretted, since we not only find in the authors abovementioned a sufficient field for the satisfaction of our curiosity, but also the most ample proofs of the irrationality of ancient principles and practice, and their total inapplicability to modern occasions. (Lawrence's General Treatise on Cattle.) On veterinary anatomy and physiology no attempts at discovery or improvement are to be traced in those writers, a singular defect considering the progress which had been made in Egypt and Greece, in both the human and comparative anatomy. Celsus is the only physician of eminence among the ancients who is reported to have written on veterinary medicine, a part of his works which has not survived; nor is probably the loss we have thereby suffered very considerable. Xenophon is the oldest veterinary writer on record; but his treatise is confined to the training and the management of the horse for war and the chace. With respect to the fragments of ancient Greek and Latin veterinary writers, collected and published by Ruellius, chief marshal, or farrier to Francis I. king of France, they appear to have been generally the works of military men, or other lovers of the horse; perhaps none of them were of medical education. We learn from the works of one of them, (Theomnestus) which is confirmed also by others, that the ancients had a knowledge of the disease called the glanders in horses and other cattle, which was denominated in those days the moist malady. The chief merit of the ancient veterinary writers consists in their dietetic rules and domestic management; they were in the habit of purging their animals, but in other respects their medical prescriptions appear to us an inconsistent and often discordant jumble of numerous articles, devoid either of rational aim, or probable efficacy. In the operations of surgery, particularly in phlebotomy, and indeed in the various methods of manual treatment and controul of their animals, the ancients were far more skilful; and what they have left on the symptoms of diseases, if of no consequence in the present advanced state of science, still serves to demonstrate that they had not been inattentive observers of animal diseases, however inferior they might be in their methods of cure. These ancient writers are yet to be esteemed superior, not only in learning and eloquence, but in professional utility, to the majority of their pupils of the fifteenth, sixteenth, and seventeenth centuries.

On the revival of learning in Europe, at the above periods, the works of the ancient veterinary writers were eagerly sought and translated in Italy and France. At the same dawn of opening light and enthusiasm for the resuscitation and enlargement of the bounds of useful science, the anatomy and physiology of the human body became the grand objects of pursuit in the Italian schools. Veterinary anatomy followed in course; and the descriptive labours of Ruini and others on the body of the horse, have not only served for a groundwork and model to all the schools of Europe since; but succeeding discoveries and improvements, notwithstanding the vast advantage of a general diffusion of light, have not been hitherto sufficiently considerable to detract in any eminent degree from the well-earned fame of those early and original anatomists. Veterinary medicine was now generally cultivated, and in some instances, under regular medical professors. We find the following names in a list of those who had written on the *res veterinaria* in Italy during that period:—Laurentius Russius, Camerarius, Apollonius, Horatio, Albeterio, Grilli, Cæsar Fiaschi, Evangelista; and afterwards in Germany and France, Gresson, Libal, Wickerus, La Brove, Vinet. Every branch of the equine economy, whether relative to harness and trappings, equitation and military menage, or riding the great horse, the methodical treatment of the hoof, with the invention of various forms of iron shoes, and their scientific adaptation, were pursued with general assiduity and success. In this latter department Cæsar Fiaschi distinguished himself; and either invented or recommended the welted shoe, proposing a substitute for calkens and frost-nails, which it appears were then in use, as well as the *lunette*, or short half-moon shoe. Those horse-nails of peculiar form, of late years recommended as a new and useful invention, under the name of concave nails, were well known in those times of which we now speak. In fact, considerable progress was made towards a perfect system of horse-shoeing, which however declined and retrograded during a long interval, until its revival in France and England within the last fifty years. Evangelista, of Milan, distinguished himself in the breaking or education of the horse, and to him is attributed the invention of the martingale.

The new veterinary science having diffused itself over a great part of the continent of Europe, could scarcely fail of occasional communication with England, where the care of diseased animals had been committed immemorially to leeches and farriers, persons generally belonging to the most illiterate class of society. It is probable that such communications became frequent during the reign of the first Tudors; for we learn from Blundeville, who wrote in the time of Elizabeth, that French and German farriers and riding-masters were not only employed by the queen, but in general by the nobility and gentry of the country. Yet the improvements in consequence of foreign aid, with regard to the medical and surgical branches at least, were by no means great, extending our view from the period of which we now speak, to the early part of the eighteenth century. No medical name appears during that long interval upon our veterinary list, nor any one of the smallest scientific pretension, we mean as far as respects the medical, anatomical, or surgical branches, that of Snape excepted, who was farrier to Charles II. and whose family, it appears by his book, had served the crown in that capacity upwards of two hundred years. Snape's anatomy of the horse proves him to have been a well-informed farrier. His anatomical system, arrangements, and nomenclature, were in course drawn from the Italian school; but he dissected, and his descriptions were confirmed by his own observation. His numerous plates are bold, accurate, and handsomely executed. Whether or not he published the book of cures which he promised, we are uninformed, but he was doubtless far better qualified for that task than those of his profession upon whom that branch of the veterinary art unfortunately devolved. Stevens, Martin, Clifford, Morgan, were very early writers among the leeches and farriers. The book of Mascal, farrier to James I. is most laughably illiterate, and we cannot help wondering with a late author how such a book could possibly pass through numerous editions in a learned age, and which even possessed learned and rational books on the same subject. The above list may be concluded with De Grey and the celebrated Gervase Markham, a contemporary of Blundeville, who continued to publish perhaps until after the Restoration, and whose works were stuffed with every absurd, barbarous, and abominable juggling trick, as well as with every useful invention which had issued from the brains of either ancients or moderns. As a specimen of the medical part of the horse leech-craft of Markham, he prescribes human ordure in certain cases for the horse, both externally and internally. Yet this man's works had a most rapid and universal sale, and continued in repute until the days of Gibson, and even long afterwards among the country leeches and farriers. It must be allowed that Markham's book contained the fullest detail of the practice of the farrier, with a delineation of his instruments, not materially different from those in present use.

Blundeville wrote sensibly and respectably on the general subject of the horse, according to the continental, the then fashionable practice. Baret in the succeeding reign, that of James I. wrote a learned treatise, entitled an Hipponomie, or the Vineyard of Horsemanship, in which he ably, and from obvious great experience, discusses all the relative branches, including the principles and practice of the race-course, and of that system of equitation peculiar to, and so generally prevalent in, England. The huge folio of the duke of Newcastle gives us the regular manege of the horse from the continental schools, with an account of the different races of the animal, in which his grace was a connoisseur of high celebrity. Throughout the same interval veterinary science in France seems to have remained almost exclusively in the hands of the marshals or farriers, amongst whom Solleysel was the most celebrated writer of the seventeenth century; his works were afterwards abridged and translated into English by sir William Hope.

Until the reign of George I. the medical care of horses and other domestic animals was confided entirely to the classes of farriers, leeches, and cow-doctors. Considering the superior value of animals in this country, the former neglect of them would appear astonishing, did it not subsist at this moment in so considerable a degree;

and that from causes easily ascertainable, but with difficulty to be surmounted. The medical system of the farriers, as delivered in their books, formed a strange medley of ancient metaphysical notions, blended with deductions from the vague and uncertain experience of illiterate men. Much of it seemed the result of mere ignorance and caprice; no little, of pure distraction. For example, in a case of farcy, De Grey orders the medicine to be administered to the ears of the horse, and stitched up therein. In case of lameness a turf was to be cut and secreted; and in proportion as the turf decayed and wasted, so would the lameness! Various of their operations, in which no shadow of reason or possible utility seems discernible, were pursued with measures of horrible barbarity; for example, in Markham, the cure by the fire or knife for the falling of the crest! These men seem to have exhausted their wits in the discovery of ingenious and knowing feats of cruelty; and it is a phrase with Markham, 'other torments there are.' The art of shoeing the horse had retrograded from the original practice of the Italian farriers, which, however imperfect, yet formed a sufficient outline for a rational system. It had become the universal practice to pare away the frog and soles of the horse's foot; and by way of making amends for such loss of substance, to substitute a shoe of massive iron, so long as to project beyond the heels. It must however be acknowledged, that a far more rational practice obtained amongst those who had the superintendance of that peculiar species of horses appropriated to the business of the turf, not only with respect to the shoeing, but every other branch of management; and as the foreign and racing species has been the grand source of improvement for the saddle and coach breeds; so the jockey system of equitation and general treatment of the horse, allowing its progressively amending defects, has ever possessed a characteristic and acknowledged superiority.

Such was the state of farriery and veterinary practice in the early part of the eighteenth century, when the former, or horse medicine and surgery, attracted the attention of Wm. Gibson, who had acted in queen Anne's wars as an army-surgeon, and appears by his writings to have been a man of much practical knowledge and sound judgment. He was the first regular professional man who attempted to improve veterinary science, which he effected in a plain and popular way, grounded on the analogy between the human and brute physiology, in course between human and animal medicine. The appearance of Gibson's book on farriery forms an era in veterinary annals; and his system in fundamentals has ever been, and is at this moment, the basis of our superior veterinary practice. He lived to publish a new edition of his chief work, about the middle of the eighteenth century. Dr. Bracken, a physician of Lancaster, a vulgar, desultory, captious, and petulant writer, yet a profound and enlightened reasoner, and of great ability in his profession, in a few years followed the laudable example of Gibson, and turned his attention to veterinary medicine. He was an exquisite practical judge of the animal on which he treated; and his work on farriery is a standard with respect to the jockey or peculiar English system, a branch which had been left untouched by Gibson. Bartlet, a surgeon in Bow-street, Covent-garden, was a most respectable, intelligent, and useful compiler from Gibson and Bracken, whose labours he circumscribed and improved. He also first introduced the new, but hypothetical and impracticable, system of short shoeing, which had then lately been promulgated in France by the sieur La Fosse, a farrier of considerable science, and a great practical veterinary anatomist. Bartlet candidly gave the rules of La Fosse for shoeing horses, without pretending to any great practical knowledge of the subject; and these rules, speculative as they were, had yet the beneficial effect of operating a considerable improvement on English practice. Fortunately the affair was soon after taken in hand by William Osmer, a surgeon and a sportsman, who had great practical knowledge of the horse, and particularly of the race-horse, that species which, whilst it improves every other, requires the greatest attention, and in an especial manner with regard to shoeing and the treatment of the feet. Osmer commenced veterinary surgeon, and published an excellent and practical, although whimsically written book on horse-shoeing, in which he reduced the speculative rules of La Fosse to the standard of his own and of English experience. His book has not probably been hitherto excelled in point of utility; and being written in a plain and popular way, is adapted to the capacities of shoeing-smiths. The earl of Pembroke also wrote a short and excellent treatise on the same subject, practical horse-shoeing and case of the feet, and on the education of the military horse. Berenger, about the same time, published a respectable work on the grand manege. Mr. Clarke, the king's farrier for Scotland, has published two valuable treatises on shoeing, and on prevention of the diseases of horses.

To revert to the commencement of the Gibsonian era. It is to be lamented that the success with which Gibson's and Bracken's improved farriery was attended did not stimulate the attempts of some regular medical men to undertake the improvement of veterinary practice in favour of our other domestic animals, and to deliver them and their proprietors from barbarous and illiterate leech-craft. Doubtless a want of encouragement must be looked upon as one of the chief causes of this defect. A book indeed appeared about the middle of the eighteenth century, under the name of Topham, treating of the diseases of horned cattle, but it proved to be a mere compilation, in which however were collected some useful hints with respect to management. As Gibson's Farriery had given rise to a great number of compilations, so Topham's book served the same purpose to the cow-doctors, many of whom copied Topham word for word, and boldly published these excerpts as the result of their own long experience and practice. Such has proved to be almost invariably the deceptive practice of this description of writers; whence the great number of similar publications, and the constant well-founded complaints against them. Mr. Lawrence, in his late General Treatise on Cattle, has taken the pains to ascertain various facts of this kind, and has given the outline of a rational system of veterinary practice, calculated for cattle and sheep, recommending the pursuit to medical men, and the liberal encouragement of such to the proprietors of cattle, and particularly to the agricultural societies.

The eighteenth century was abundantly fruitful in veterinary pursuits and publications. France took the lead; but a zeal for the improvement of this branch of science also pervaded Germany and the northern states, and colleges were established in various countries, wherein the science has been since regularly cultivated. Baron Haller collated the various continental writers on black cattle and sheep; another catalogue of them may also be found in the Giournal di Literati of Italy. Since these collections, the number of veterinary writers has been immense on the continent, not improbably for a reason already assigned. Few or none of them have been translated into our language, excepting detached parts of the works of the eminent French writers, La Fosse and Bourgelat. Our late professor Saintbel was a disciple of these celebrated veterinarians, and drew his geometrical proportions of the race-horse Eclipse from the tables of the latter. The truth and correctness of these geometrical principles have been since controverted by Mr. Wilkinson. Indeed, several speculative positions laid down in these tables do not accord with English practical experience; nor is the continental veterinary system, it is said, altogether calculated for the practice of this country, one great proof of which presents itself in the failure of the celebrated method of shoeing by La Fosse. The French have improved the anatomical and surgical branches of the veterinary art, rather than the medical; the English have made the greatest improvements in the latter: it is not improbably a parallel case with respect to human medicine.

Since the establishment of a veterinary college at St. Pancras, near London, in 1792, a great number of veterinary surgeons, receiving their diploma from thence, have been dispersed in the army and throughout the country, to a great national advantage, in the surgical and medical treatment of horses. A number of farriers also annually take the advantage of improving themselves at this seminary; but it is to be lamented that the light of veterinary science has hitherto shined but dimly and imperfectly on the other domestic animals. A great number of veterinary publications have issued from the press within this last period; and the two professors Saintbel and Coleman, with Messrs. White, Boardman, Blane, and many others, have laudably and usefully distinguished themselves in this way. Mr. Blane appears to have taken great pains in a new branch of veterinary science, as it relates to that useful domestic the dog. He has also published the anatomy of the horse. But the anatomical drawings and engravings of the bones, muscles, and many of the blood-vessels of the horse, of the justly celebrated horse-painter Stubbs, are held superior to any thing we possess of this kind.

The objects of farriery we have shown, are the anatomy, physiology, pathology, medical and surgical care, and shoeing, of the horse. Dr. Crooke, quoted by Snape, affirms, that the motions of the heart, the arteries, the midriff, the brain, and guts, are the same in beasts as in men. Mr. Bracey Clarke observes, that "to describe each part of the horse individually and separately, would be often only repeating the more elaborate descriptions of the human anatomy, more frequently than those but little conversant with this subject would suspect. Many of the viscera, and even the myology of the trunk and extremities, often correspond in their principal circumstances." Snape further says, that "in some regards anatomy is more necessary to farriers than to physicians, in order to find out disorders; for besides the pulse and the urine, and the pathognomonic signs of each distemper, the physicians are assisted in their enquiries, moreover, not to say chiefly, by the complaints and relations of the patients themselves; whereas a farrier, having to do with a dumb creature, must be very curious in his knowledge of the parts, with their offices, and of the sympathy or consent that one part hath with another; or else, seeing all his information must be of his own hammering out, he is like to make but a short discovery of the distemper." Add to the above observations, the analogy which modern experience has found to subsist between human and animal medicine, so far as our domesticated animals are concerned; and it will appear to whom veterinary science must necessarily be confined; and that an illiterate and ignorant class, whose laborious occupation must for ever preclude study and reflection, are totally incapable of the practice of medicine, whether human or animal. Thus the countenance and encouragement of so gross a deviation from rectitude and common sense must be constantly attended with loss and disappointment to the proprietors, and cruelty to their animals, exclusive of the moral breach of holding out to a numerous set of men the arts of imposition and legerdemain as a livelihood. The branches of the veterinary art, justly appropriate to the farrier and the cow-leech, are shoeing the horse and the labouring-ox, administering drenches, obstetric practice, bleeding, firing, and common surgical operations, under the guidance of a scientific veterinarian. Even shoeing, which seems most to appertain to the province of the common operator, has never been, in a single instance, improved by that class, but invariably by men of science: on the contrary, every improvement has met the strenuous opposition of the common farrier, until he has been gradually drawn into it, and almost imperceptibly to himself. Nor is the province we have assigned to these people, by any means, narrow or confined, but most ample, and affording a fair scope for both industry and good natural talents. Yet far be it from our intention to exclude them from the benefits either of attending the veterinary college or of consulting useful and practical books, which, in fact, are the true and only means to accomplish them in the fair and proper objects of their profession. We neither counsel nor desire any thing farther, than that such men, who may be much more suitably and advantageously employed, be as little as possible permitted to dabble in medicine.

It has of late been averred, in a sense far too general, that analogies fail, as well in anatomy as in the effects of medicine, between the human and those animals of which we treat. It is true the latter are quadrupeds, and their structures is of greater magnitude, and necessarily varies from ours; their integuments are thicker, and their general substance more solid. It requires, therefore, and the proportion has been long ascertained with sufficient accuracy, the application of a more powerful stimulus, in all given cases; in many, peculiar modes of administration. Certain common articles of the materia medica, namely, rhubarb, jalap, and the pur-

ging salts, it has been said of late, have no perceptible effects on the body of the horse, an assertion which ought to be received with a degree of caution. It is true, jalap and rhubarb, which were formerly, and particularly by Gibson, recommended as ingredients in purgative formulæ, will scarcely have any purgative effect if used by themselves; the latter, however, at least is certainly capable of answering many beneficial intentions in veterinary medicine; but its high price is doubtless a strong objection. Purging salts, it is acknowledged, will not often excite liquid dejections in horses, although they will in cows; but in the former, judiciously administered, they evacuate great loads of softened excrement, have excellent cooling and diuretic properties, and are well calculated for horses much confined in hot stables, and for those of delicate constitutions. All, or the far greater part, of the most powerful and efficacious medicines, both of the tonic and debilitating class, have a signal and analogical effect on the constitution of the horse. Nor is the common opinion, that the horse, living upon plain and simple food, has very little or no occasion for medicines, deserving of the smallest attention, any otherwise than as applied to the horse ranging at large in a state of nature. Labouring in the service of man, and confined to the dense and foul air of the stables, often in a constant state of luxurious repletion, exposed also to perpetual alternations of heat and cold, his body becomes subject to a variety of diseases, some of them of a most malignant type; and with respect to accidents he must, from the nature of his severe services, be necessarily subject to a greater variety than any other animal. The above common-place opinion has ever been brought particularly to bear against the practice of purging horses, by which nevertheless they receive the most obvious and important benefits, and of which they seldom fail to have occasional need, whilst kept at hard meat in the stable. In fact, considering the obstruction and heat to which they are liable from the vast volume of their intestines, and the dryness and solidity of the food with which they are fed, it should seem probable that no animals stand more in need of artificial evacuants. The very circumstance of the length of their intestines has indeed been adduced as a proof of the impropriety and even danger of administering to them purgative medicines; and various instances of fatal effects therefrom have been proved. Sotteysel, the French writer, argued in this way; and advised the substitution of perspirants and diuretics; and notwithstanding the eminent success which every one accustomed to the superior management of horses, has experienced from purging them, the above superficial and groundless notion is occasionally revived even at present. The grand object is the removal of visceral infraction and obstruction, the common parent of almost every morbid evil in the horse; and this can at no rate be effected by diuretics, although they gave a partial, but illusory, and thence dangerous relief.

Nor are alteratives, in a general view, so advantageous as mild and well apportioned purges, which seem, in a particular manner, adapted and friendly to the constitution of the horse, filling him with renovated spirit and vigour, and increasing his appetite and strength. Purging the horse is perhaps to be considered as an English practice, alteratives and diuretics being in more general use on the continent; and with respect to the danger of purging, the experience of a century has proved that to consist merely in the abuse and the use of bad drugs. Purging composes a material branch of the celebrated jockey or Newmarket system, which, with its imitations, have produced a perfection of habit and condition in the horse, universally admired by foreigners, and peculiar to that country. There is yet another opinion occasionally delivered, which we trust may not be unsuccessfully controverted: we advert to the pretended infant and imperfect state of veterinary science. The science of farriery has long been in a respectable and even mature state in Great Britain, however generally deficient the practice; and we surely have at this time an undoubted right to expect a general and practical improvement.

Horses are particularly subject to catarrhal fever, pneumonia, influenzal and epidemic colds, rheumatism, asthmatic complaints, affections of the liver, colic, and blindness. They also share in common with human nature the maladies of apoplexy, spasm and convulsions, affections of the kidneys and urinary bladder, diabetes, dropsy, fever, and cutaneous affections.

The peculiar diseases of the horse are glanders, farcy, grease, strangles, poll evil or abscess, and they are particularly liable to injury and lameness in the lower extremities.

With respect to their diseases, the glanders, it is well known, has ever been the veterinary opprobrium, nor have we yet, after an infinity of attempts at various periods, advanced one step towards a probability of cure, speaking of the chronic species; nor is such an attainment perhaps an object of much consequence or interest from the length of time the cure must necessarily require, and the little subsequent use to be expected from the patient. The acute or incipient glanders will generally submit to proper remedies and care. The disease is atmospheric and catarrhal, and occasionally, but perhaps not so frequently as in common supposed, caught by contagion of other horses. Oxen and sheep are affected by the glanders; the latter particularly, on being early shorn in cold springs, under the influence of easterly winds. Broken wind in the horse, as its designation would seem to intimate, is irreparable; and there is a relative circumstance for which perhaps it is not easy to account, namely, that if a horse of this description be turned to grass for any length of time, on taking him back to the stable his malady shall be considerably increased, although, perhaps, if continued constantly abroad, he might remain as at first, or experience some amendment. In general, the diseases of horses, supposing skill in the practitioner, and an acquaintance with our best written authorities, may be treated very successfully, and upon a very near level in that respect with the human patient. Amongst, or rather the chief of, those irreparable injuries which the horse, from his hard services, is liable to sustain, must be reckoned repeated strains of the tendons. For a chronic case of that kind it is seldom possible to obtain a cure; and although the only remedy to be depended on is a long run at grass, yet, as has already been observed of broken wind, a horse in a confirmed case of injured tendons, frequently

returns worse from grass than he was whilst in the stable. (Lawrence on Horses.) These injuries are commonly seated about the well-known back sinew of the leg, and among that multitude of tendons (in Snap's language) that descend into the coffin-joint. It has been said that our knowledge in that most important branch, tendinous lameness, has been on the decline since our late unreserved adoption of the principles of the French veterinary school, and accession to the hypothesis of the inelasticity and immobility of tendons, on which it is asserted, that there can exist no such malady as a strained tendon, producing morbid laxity subsequent to inflammation. The new opinion seems to confine the disease to inflammation simply, and the cure to the dispersion of the inflammatory symptoms. Now constant experience has proved, that those merely attendant symptoms may be soon ridded, and yet the strain or lameness continue. (See Bracken on the nature of strain.) This is a most material point of the veterinary art, and involves the great and necessary qualification of detecting the seats of lameness in horses. English horses in general are extremely subject to tendinous lamenesses, both from their natures, as being so much mixed with the delicate racing breed, and from their being forced to more speedy and severe exertions than the horses of any other country. Hence it is said that the best continental veterinarians, as defective in practical experience, are imperfectly skilled in the lamenesses in question, and their proper treatment; and that in order to attain considerable knowledge in this branch, and to be able to ascertain the seats of lameness, it is absolutely necessary for the veterinarian to experiment and practise with the living as well as the dead subject, and to advance far beyond the limits of the riding-school and parade. On this disputed subject, on the turf, on the theory and practice of humanity to animals, and on the purchase, qualifications, and performances of horses, Mr. Lawrence's Philosophical and Practical Treatise may be consulted with much advantage.

The grease.—This discharge seems peculiar to the horse, as in the disorder properly so called, and in molten-grease or the body-founder. The grease in the legs is an extravasation, or bursting from the vessels, and afterwards through the skin, of serum, or simple humour, either from defect of exercise, or any cause of obstructed circulation in those depending parts. Round, fleshy-legged horses, like those, for example, of the old Suffolk cart breed, are constitutionally liable to grease; on the contrary, the flat, sinewy-legged, and in general as horses approach the thorough-bred or racing-kind, they are the least liable to this defect. Want of good grooming, however, the legs remaining in their dirt in the stall, or the horse not lying down, will grease any species of horses. This malady never affects the horse at grass, which points out the readiest cure; and with respect to such as are constitutionally liable, the only way to preserve them sound is to keep them abroad. A slight case in the stable gives way to thorough cleansing and ablution with soap and water, the discharge being afterwards dried up with astringent poultices, lotions, or powders. Purges or alterants may be exhibited according to the nature of the case. A confirmed and inveterate case is extremely difficult of cure, requiring powerful escarotic applications.

Oslets, splents, spavins, ringbone, curb, thoroughpin, &c. are bony excrescences differently posited, originating in an extravasation by pressure of weight or over-exertion, of the mucilage or oil of the joints, which gradually condenses and becomes ossified. Splents and oslets upon the shank, not affecting the joint, may not occasion lameness, and even admit of dispersion and cure by friction, blistering, and repellents, if taken early, and before their substance is become too solid. The ringbone is an ossification or bony swelling, surrounding, as its name expresses, like a ring, the coronet or summit of the hoof; it proceeds from the contiguous small pastern bones. Being suffered to come to maturity, it is incurable by any possible remedy which can leave the horse sound. The spavin is also a preternatural bone, situated on the inside beneath the hock, and extending in its course to the joint. It is generally a hopeless case. Removing the part with a chisel was formerly attempted; but blistering and caustics are the more usual modes of attempt at cure. A very powerful caustic method, recommended by Osmer, was within these few years tried upon a celebrated trotter, but it killed the horse in three days. Perhaps Gibson's cure of a confirmed spavin is the most successful one on record. See his Farriery. The thoroughpin is posited withoutside, and between the bones of the hock. An incipient case may admit a remedy; and we lately witnessed a perfect cure of this malady in about three months by a perpetual blister. The curb is found on the back part of the hock. The bog-spavin withinside, in the cavity of the hock, is a tumour frequently of considerable bulk, of the nature of the windgall. It produces lameness; and that part of the horse, although generally forgotten, should be examined in purchase.

Windgalls are well-known distinct tumours on the pastern-joints, filled with extravasated fluid, which either forms capsules or bags for itself, or such bags are an enlargement of the natural bursæ mucosæ, or mucous capsules, which are found wherever tendons pass over each other, or over any solid part, and serve the purpose of lubricating with their mucus those tendons. Horses are in general subject to this infirmity in proportion to the racing blood they have; and we have seen common bred hacks, in which no labour would produce a windgall. Work will generally bring them more or less; but bandage and astringent lotions, with runs abroad, and the loose stable, are the only preventives. The general palliative remedies are as above, and blistering. When they feel tense and elastic, they may not be an immediate occasion of lameness; but if flabby and inelastic, and of considerable bulk, the tendons are debilitated, and there can be little expectation of soundness. Bracken made a successful experiment of opening, and discharged the fluid of the bog-spavin; and after him, Lawrence that of the windgall. See their accounts.

Corns are bruises or compressions of the horney sole near the quarters; if dry, to be pared out with the knife, and treated with spirituous and healing applications, applying the bat-shoe, if it is necessary to work the horse.

The sand-crack is a cleft in the external part of the

hoof either vertical or with the grain, occasioned by too great dryness in course, and to be prevented by the opposite. Rest the horse, bind the hoof, pare and dress the part. Gibson, in some cases, used the cautery moderately heated.

The quittor, in French *javart*, is a hard round lump or excrescence on the coronet, between hair and hoof, on the one or the other, but usually on the inside quarter of the foot; confirmed, it is a very bad case, generally inducing in the cure the ill consequence of a false quarter or seam adown the foot, from loss of substance; subsequently to which the horse is seldom, perhaps never, rightly sound. The founder of the foot is probably rheumatic, or at least often originates in a similar cause.

Mallenders are chinks or clefts behind the knees of the fore-legs; sallenders are the same defect in the hinder legs. They discharge matter, which must be treated with thorough ablution, repellents, and mercurial washes or unguents, internal alteratives or purges being also administered. Wash thoroughly with a linen rag and soap-suds warm the wound of the broken knee, in order to discharge the gravel or dirt which may have intruded. Bathe with brandy, or bind upon the part tow dipped in tincture of myrrh and brandy. In case of swelling, it may be useful to poultice, and afterwards bathe with brandy and vinegar warm. Sheet-lead bandaged on the part may make the hair grow smooth.

Lameness in the shoulder is comparatively a very rare occurrence, notwithstanding which grooms and farriers in general, from a deceptio visus, and not being skilled in a manual detection of affections of the parts, generally imagine every lameness to exist in the shoulder. In an obvious and real lameness of the shoulder, during the tension and inflammation, rowelling is necessary, with spirituous and astringent fomentations; but that which is of far the greatest consequence, sufficient time to repose at grass.

Strains in the loins and couplings.—A strengthening charge and embrocation may have some good effect; but remaining at rest abroad, for a considerable length of time, is the only cure when the case is curable.

Lameness of the hip or whirlbone, and of the stifle-bone, similar to the small cramp-bone in a leg of mutton.—In the former case the symptoms are, swinging of the limb, or its being longer than naturally: in trotting the horse droops backward upon the heel. Time and rest, with applications as above, cure a recent case of this kind; but from neglect it becomes incurable. The whirl-bone or hip, is sometimes depressed or beat down with violence, and so remains, the horse yet continuing useful. A mare in this state, thence called slip, even-raced. On lameness of the stifle, Snape says, "It is worth the dissector's taking notice of these three last muscles, how they are joined all in one, just at their crossing the stifle, where they make one broad and very strong tendon, which spreads over and involves the patella, or little bone of the stifle, and ties it so fast in its place, upon the jointing of the thigh-bone with the tibia, that it is very seldom displaced, or indeed never. For although by distensions or strains we often have this part affected, yet never did I see an absolute dislocation in it. The patella indeed may be, and often is, wrenched either to one side or the other, as the accident may happen." Cure consists in rest, and the usual treatment of strains: the tumour will sometimes, but rarely, suppurate, which is a present remedy.

Teeth and age of the horse.—The horse has forty teeth: twenty-four double teeth or grinders, four tushes or single teeth, and twelve front teeth or gatherers. Mares in general have no tushes. The black marks or cavities, which denote the age, are to be found in the corner front teeth, adjoining the tushes. Horned cattle have similar marks in the teeth. At four years and a half old, the mark-teeth are just visible above the gum, and the cavity is very conspicuous. At five, the horse sheds his remaining colt's teeth, and his tushes appear. At six, his tushes are up, and appear white, small, and sharp; near which is observable a small circle of young, growing, flesh: the horse's mouth is then complete, and the corner teeth filled up. At seven years old, the two middle teeth fill up. At eight, the black marks vanish, and the horse's mouth is said to be full, and himself aged. The French farriers aver that the marks remain in the teeth of the upper jaw until the horse is twelve years of age; but we believe this to be fortuitous.

The lampas, from the Latin lampascus, is an inflammation and tumour of the first bar of the young horse's mouth, adjoining the upper fore teeth, which prevent his chewing. If scalded mashes, warm gruel, Glauber's salts in the water, and bleeding, do not remove the inconvenience in a week, lightly cauterize the tumid parts, without penetrating deep enough to scale off the thin bone beneath the upper bars. Wash with salt and water first, afterwards heal with a mixture of honey and brandy or port wine. La Fosse and others have denied the existence of this slight malady; but we have witnessed it repeatedly. We have also seen the haw in the eye, and the probability of its obstructing the sight, with its successful excision, a very small part of the substance being extirpated; the proper rule, should excision ever be recurred to, in truth a matter of doubt, as a painful operation. The haw is a preternatural enlargement and sponginess of the caruncle, a fleshy substance in the inner corner of the eye, causing the ligament which runs along the verge of the membrane to compress the eyeball like a hoop.

Shoeing.—The veterinarian who is ambitious of being thoroughly grounded in this important branch of his art, should study attentively the principles and rules of La Fosse, Bourgelat, and Osmer, comparing them with what has been since written by Mr. Clarke, and the professors Saintbel and Coleman. One or two of the ancients have mentioned the iron shoe, but it did not probably come into general use in Europe until the fifteenth century. It has been often hinted that horses might be accustomed to labour without shoes, and that exposure to the hard ground would render their soles obdurate, a consequence which is also pretended to result from their standing upon a hard, unlittered pavement, with abundance of similar and futile sophistry. The distressing accidents which have happened from the loss of a shoe, in consequence of which, from a few hours speedy travel by night, the hoof has been worn away to the very bones of the foot, are a full and lamentable answer to such follies. Indeed, in hot and dry countries, where the hoof is na-

turally hard, and the exertions of the horse very limited, compared with those he undergoes in this country, he is perhaps generally ridden without shoes. In the Welsh mountains this is also occasionally practised: but upon our roads, particularly in wet weather and in winter, the walls, sole, and frog, would be rubbed away and totally destroyed, granting the practice was used with a young and perfect foot, which never knew the protection of a shoe; nor have we any horses but would flinch under such an exposure of their feet.

A young and perfect foot has a firm and level bearing upon the circular crust or wall, and the frog, which however is an elastic substance, and the fulcrum or rather cushion of the main tendon. The frog is yet not a solid and steady support, but springs or contracts on touching the ground. In some very concave feet, of bred cattle particularly, the frog is not of sufficient bulk to reach the ground; and in thousands of horses shod by common farriers, the case is similar, from the part being reduced by constant wear and paring, and by the improper height of the shoe-heels: yet the frog does its office, although surely not in so perfect a way. In general, the foot should be suffered to retain its natural form and substance on applying the shoe, the toe only being shortened, the walls or crust pared even, the sole, bars or binders, and frog, being left intire, bating a little trimming away of loose and decaying substance: instead of which, the common farriers pare the sole without mercy, almost extirpate the frog to make it appear neat, and cut away at every shoeing half the substance of the bars in order to open the heels, the direct way to shut them up, or narrow them; since one great use of the frog and bars is that of an interposing substance to keep the heels open and spreading. It must then be acknowledged, that some naturally tough, thick, and quick-growing soles may require paring, or they otherwise are inconvenient, and produce uneasy sensations in the horse; but this is perhaps never the case with respect to the frog, which, coming in contact with the ground, would always be thereby sufficiently reduced. As there are too many hoofs with thin and weak walls or crusts, in which it is difficult for the smith to find nail-hold, and from which by consequence scarcely an atom can be spared to the paring-knife, so there are others of the concave and deep kinds, in which the surrounding edges or crusts are so high and tough, that it is absolutely necessary and salutary to the foot to soften it by paring them down occasionally, bringing the pittance of a frog nearer to the ground, disposing it to enlarge and thereby expand the narrow and wiry heels.

A shoe should be so formed, that the horse may stand steady and firm upon his natural level, namely to bear equally upon the toe and the surrounding wall or crust; the frog, if in its perfect and natural state, touching the ground. The shoe-heels may be reduced in substance, in order to enable the frog, defective in size, to touch the ground, provided a too great tenderness and sensibility in the frog, a very common case even in a colt, do not forbid it. In that circumstance, attended by a soreness or defect in the quarters also, the shoe-heels must be of sufficient thickness to do the office of the frog, and preserve the just level of the foot; for with reduced quarters and shoe-heels, and no frog to support the tendon, the latter must suffer great distension even from the mere natural weight of the horse; and in this way, from a forced attempt at improvement of the frog, by certain speculators, great numbers of horses were instantly lamed. Our common farriers, however, have usually run into the opposite defect, and by extremely thick shoe-heels, and even the addition of chalkings to the fore-shoes, have thrown the weight of the horse chiefly upon his toes. They are doubtless much improved in their practice in most parts of England, but in some, the old dangerous and destructive form of shoe is still retained; long, broad, and convex in the external surface, and concave next the foot. Such is precisely the common shoe of the draught-horse even in the metropolis, where one would suppose common sense, in the course of more than fifty years, must have had time to operate. Yet we lately witnessed the heart-rending exertions of four noble animals to draw up Holborn-hill a most ponderous load, the stones presenting a surface of glass, to the slippery convex, or rather globular surfaces of the horse-shoes. It is impossible but these willing animals must have ineffectually wasted more than half their powers, that is to say, the strength of the four was reduced to less than that of two, by the senseless form of their shoes; and we represented to the driver, the strong probability that a quarter of an hour of such excessive exertion, might injure the horses in a greater degree, than six months of fair and regular although hard labour. Shoes should be made of the best iron well hammer-hardened, but not too much softened by the fire. Of such stuff, the shoe should be as light as the horse could bear; but it must be remembered, there must be a sufficient substance of iron in proportion to the weight of the horse, or in travelling, he will suffer from jarring or concussion of the bones of the foot. Narrowness of the web of the shoe is indubitably an advantage, but some feet require and must have more cover. The length of the shoe in general, should approach, never exceed, the extremity of the heel, and should decrease in width at the heel, excepting a need to defend weak quarters. The surface of the shoe presented to the earth should ever and without exception be flat, and even when practicable, hammered somewhat concave or hollow, which gives a firmer tread on slippery surfaces. This is a very old idea, and although professor Saintbel did not succeed in reducing it to practice with thin shoes, it can meet with no obstruction in the heavy shoes of cart-horses, which are however always made far heavier than necessary, from being forged of inferior materials, a consideration for the opulent proprietors of draught-horses. The shoe must rest entirely on the wall or crust, never on the sole, on which the pressure would occasion lameness. To this end, that part of the shoe applied to the crust must be flat, consisting of a rim or margin according in breadth, with the crust, and of equal thickness around the outside of the rim, in the middle of which exactly the nail-holes are to be made; from this margin internally, towards the sole, the shoe must be formed gradually thinner, that it may not press upon the sole. Osmer farther directed, and it has been invariably followed by the best practitioners, that the shoe should be made to stand somewhat wider at the extremity of each heel, than the foot itself; otherwise, as the foot grows in length, the heel of the shoe in a short time, gets within

BB. The blade-bone or scapula.
C. The humerus, or shoulder-bone.
DD. The bones of the leg, or fore-arm, consisting in each of the radius and ulna.
EE. The joints of the knees, with the small ranges of bones.
FF. The posterior parts of the knee-joints.
GG. The shank-bones, consisting in each of the cannon bone, and the two metacarpal, or splent-bones.
HH. The great pastern bones, with the two sesamoid bones of each fetlock.
II. The lesser pastern bones.
KK. The bones of the feet, consisting in each of the coffin and navicular bones, with the lateral cartilages.
LL. The bones of the pelvis, called ossa innominata.
MM. The thigh-bones.
NN. The bones of the hind-legs, consisting in each of the tibia and the fibula.
OO. The points of the hocks.
PP. The small bones of the hocks.
QQ. The bones of the instep; consisting in each of the cannon bone and two metatarsal bones.
RR. The great pastern and sesamoid bones of the hind-legs.
SS. The little pastern bones of the hind-legs.
TT. The coffin and navicular bones of each hind-foot, with the lateral cartilages.
V. The sternum, or breast-bone.
X. The point of the sternum.
YY. The ribs.
Z. The cartilaginous ends of the ribs on the breast and abdomen.
I. II. III. IV. V. VI. VII. The seven vertebræ of the neck.
1. 2. 3. 4. 5. 6. 7. 8. 9. 10, 11. 12. 13. 14. 15. 16. 17. 18. The eighteen vertebræ of the thorax and back.
1. 2. 3. 4. 5. 6. The six vertebræ of the loins.
1. 2. 3. 4. 5. The five spines of the os sacrum.
1. 2. 3. 4. 5. 6. 7. 8. 9. 10. 11. 12. 13. 14. 15. 16. 17. 18. The eighteen joints of coxendix and tail.

Figure 2.—Representing the intestines of a horse as they appear in their natural situation when the abdomen is laid open.
AAAAAA. The colon, with its various circumvolutions and windings, together with its numerous folds, and under which lie the small intestines.
B. The cœcum, or blind gut.
C. The rectum.

Figure 3.—Shows the horny sole *a* raised from the fleshy sole *c c c;* round which is the enchannelled flesh *y*, placed in the falcus of the inner surface of the hoof, the horny part of which is soft and white.

Figure 4.—Represents the under part of the fleshy sole *c*, raised from the foot-bone, or coffin-bone, *d d d; g* the covering or sheath of the tendo Achillis; *z* the cartilage; *y* the edge of the fleshy sole confined in the furrow of the channelled horny substance.

Figures 5 and 6.—Give the bottom or base of the foot; *a a a* the horny sole; *b* the frog; *z* the hoof towards its lower edge, called the crust or wall of the foot.

Figures 7 and 8.—Modern shoes.

FARTHING *of gold*, a coin used in ancient times, containing in value the fourth part of a noble, or 20*d.* silver. It is mentioned in the stat. 9 Hen. V. cap. 7. where it is enacted, that there shall be good and just weight of the noble, half-noble, and farthing of gold.

Farthing *of land*, seems to differ from Farding-*deal;* for in a survey-book of the manor of West-Hapton, in Devonshire, there is an entry thus: A. B. holds six farthings of land at 126*l.* per ann. So that the farthing of land must have been a considerable quantity, far more than a rood.

FASCES, in Roman antiquity, axes bound up together with rods or staves, and carried before the Roman magistrates as a badge of their authority and office. The use of the fasces was introduced by the elder Tarquin, as a mark of sovereign authority: in aftertimes they were borne before the consuls, but by turns only, each his day. They had twelve of them carried by so many lictors. After the consuls, the prætors assumed them, and Censorinus observes they had only two, though Plutarch and Polybius give them six. In the government of the decemviri, it was the practice at first for only two of them to have the fasces. Afterwards each of them had twelve, in the same manner as the kings.

FASCETS, in the art of making glass, are the irons thrust into the mouths of bottles, in order to convey them into the annealing tower.

FASCIÆ, in astronomy, certain parts on Jupiter's body resembling belts or swaths. They are more lucid than the rest of that planet, and are terminated by parallel lines, sometimes broader, and sometimes narrower. Mr. Huygens observed a facia in Mars much broader than those in Jupiter, and possessing the middle part of his disk, but very obscure.

FASCINES, in fortification, faggots of small wood of about a foot diameter, and six feet long, bound in the middle, and at both ends. See Fortification.

FASCIOLA, in zoology, the fluke or gourd worm: a genus of insects of the order of vermes intestina; of which the characters are these: The body is flattish, and has a vent-hole at the extremity and on the belly. There are several species. 1. The hepatica, or liver-fluke, grows to two-thirds of an inch in length, though it is more usually met with not half that size; and its breadth is nearly equal to two-thirds of its length. It is flattish, but somewhat rounded on the back, and has about eight deep longitudinal furrows in two series; its skin is soft and whitish, with a tinge of brown. The hinder part is rounded, the fore part is furnished with a large mouth. It bears some resemblance to the seed of the common gourd, whence it has acquired the name of the gourd worm. It is found in fresh waters, in ditches, at the roots of stones, sometimes in the intestines, and often in the substance of the other viscera in quadrupeds. It often infests the liver of sheep, and on that account is called hepatica. Bags with salt in them should be placed in the fold, that sheep might lick them, which is a good remedy. 2. The intestinalis, or intestinal fluke, is of a long slender form, if extended; when contracted, of a suboval form; inhabits the intestines of fresh-water fish, especially the bream. 3. The barbata, is white, with transverse papillæ in the mouth. It is of an oblong shape, and about the size of a cucumber-seed.

FASHION-PIECES, in the sea language, are two

compassing pieces of timber, into each side of which is fixed the transom.

FASTERMANS, among our Saxon ancestors, were pledges or bondsmen, who were answerable for each other's good behaviour.

FASTI, in Roman antiquity, the calendar wherein were expressed the several days of the year, with their feasts, games, and other ceremonies. There were two sorts of fasti, the greater and less; the former being distinguished by the appellation of fasti magistrales, and the later by that of fasti calendares. The greater fasti contained the feasts, with every thing relating to religion and the magistrates. The lesser were again distinguished into the city and country fasti, each adapted to the people for whom they were designed. In all these fasti, the court-days, or those whereon causes might be heard and determined, were marked with the letter F; these days were called fasti, from fari, to speak or pronounce; and the other days, not marked with this letter, were called nefasti.

FASTI CONSULARES, was also a tablet, or chronicle, wherein the several years were denoted by the respective consuls, with the principal events that happened during their counsulship. And hence, the term fasti is still applied to the archives and public registers of a nation.

FAT, in anatomy, an oleaginous or buty-raceous matter, secreted from the blood, and filling up the cavity of the adipose cells.

FAT, in chemistry. See OIL.

FAT, in the sea-language, signifies the same with broad. Thus a ship is said to have a fat quarter, if the trussing in or tuck of her quarter is deep.

FAT, perhaps properly vat (vas or vessel), denotes likewise an uncertain measure of capacity. Thus a fat of isinglass contains from $3\frac{1}{4}$ hundred weight to four hundred weight; a fat of unbound books, half a maund, or four bales; of wire, from 20 to 25 hundred weight; and of yarn, from 220 to 221 bundles.

FATA MORGANA, a very remarkable aerial phenomenon, which is sometimes observed from the harbour of Messina and adjacent places, at a certain height in the atmosphere. The name, which signifies the Fairy Morgana, is derived from an opinion of the superstitious Sicilians, that the whole spectacle is produced by fairies, or such-like visionary invisible beings. The populace are delighted whenever it appears; and run about the streets shouting for joy, calling every body out to partake of the glorious sight.

This singular meteor has been described by various authors; but the first who mentioned it with any degree of precision was father Angelucci, whose account is thus quoted by Mr. Swinburne in his Tour through Sicily: "On the 15th of August, 1643, as I stood at my window, I was surprised with a most wonderful delectable vision. The sea that washes the Sicilian shore swelled up, and became, for ten miles in length, like a chain of dark mountains; while the waters near our Calabrian coast grew quite smooth, and in an instant appeared as one clear polished mirror, reclining against the ridge. On this glass was depicted, in chiaro-scuro, a string of several thousand of pilasters, all equal in altitude, distance, and degree of light and shade. In a moment they lost half their height, and bent into arcades, like Roman aqueducts. A long cornice was next formed on the top, and above it rose castles innumerable, all perfectly alike. These soon split into towers, which were shortly after lost in colonnades, then windows, and at last ended in pines, cypresses, and other trees, even and similar. This is the Fata Morgana, which for twenty-six years I had thought a mere fable."

To produce this pleasing deception, many circumstances must concur, which are not known to exist in any other situation. The spectator must stand with his back to the east, in some elevated place behind the city, that he may command a view of the whole bay; beyond which the mountains of Messina rise like a wall, and darken the back-ground on the picture. The winds must be hushed, the surface quite smooth, the tide at its height, and the waters pressed up by currents to a great elevation in the middle of the channel. All these events coinciding, as soon as the sun surmounts the eastern hills behind Reggio, and rises high enough to form an angle of 45 degrees on the water before the city, every object existing or moving at Reggio will be repeated a thousandfold upon this marine looking-glass; which, by its tremulous motion, is in a manner cut into facets. Each image will pass rapidly off in succession as the day advances, and the stream carries down the wave on which it appeared. Thus the parts of this moving picture will vanish in the twinkling of an eye. Sometimes the air is at that moment so impregnated with vapours, and undisturbed by winds, as to reflect objects in a kind of aerial screen, rising about 30 feet above the level of the sea. In cloudy heavy weather they are drawn on the surface of the water, bordered with fine prismatical colours.

To the above account we shall add the following, by another observer: "In fine summer days, when the weather is calm, there rises above the great current a vapour, which acquires a certain density, so as to form in the atmosphere horizontal prisms, whose sides are disposed in such a manner, that when they come to their proper degree of perfection, they reflect and represent successively, for some time, (like a moveable mirror) the objects on the coast or in the adjacent country. They exhibit by turns the city and suburbs of Messina, trees, animals, men, and mountains. They are certainly beautiful aerial moving pictures. There are sometimes two or three prisms, equally perfect; and they continue in this state eight or ten minutes. After this some shining inequalities are observed upon the surface of the prism, which render confused to the eye the objects which had been before so accurately delineated, and the picture vanishes. The vapour forms other combinations, and is dispersed in air. Different accounts have been given of this singular appearance; which for my part I attribute to a bitumen that issues from certain rocks at the bottom of the sea, and which is often seen to cover a part of its surface in the canal of Messina. The subtile parts of this bitumen being attenuated, combined, and exhaled with the aqueous globules that are raised by the air, and formed into bodies of vapour, give to this condensed vapour more consistence; and contribute, by their smooth and polished particles, to the formation of a kind of aerial crystals, which receives the light, reflects it to the eye, and transmits to it all the luminous points which

colour the objects exhibited in this phenomenon, and render them visible."

FATHER, in church history, is applied to ancient authors who have preserved in their writings the traditions of the church. Thus St. Chrysostom, St. Basil, &c. are called Greek fathers, and St. Augustine and St. Ambrose Latin fathers. No author who wrote later than the twelfth century is dignified with the title of Father.

FATHER AND SON. In law the father shall not have action for taking any of his children, except his heir; and that is, because the marriage of his heir belongs to the father, but not of any other of his sons or daughters. And the father has no property or interest in the other children, which the law accounts may be taken from him. Cro. Eliz. 770.

The father is obliged by the common law to provide for his children. Lord Raym. 41.

Justices cannot order a maintenance for a child to be paid by the father, without adjudging that the child is poor, or likely to become chargeable. Id. 669.

FATHOM, a long measure containing six feet, chiefly used at sea for measuring the length of cables and cordage.

FAVORITO, in music, as choro favorito, a chorus in which are employed the best voices and instruments, to sing the recitatives, play the ritornellas, &c.; this is otherwise called the little chorus, or choro recitante.

FAUSSE-BRAYE, in fortification, a small rampart without the true one, about three or four fathom wide, and bordered with a parapet and banquet. SEE FORTIFICATION.

FEAL-DIKES, a cheap sort of fence common in Scotland, built with feal or sod dug up by the spade from the surface of grass-ground, consisting of the upper mould rendered tough and coherent by the matted roots of the grass thickly interwoven with it. If only a very thin bit of the upper surface is pared off with a paring-spade, the pieces are called divots. These being of a firmer consistence, are more durable when built into dikes than feal, but much more expensive also.

FEALTY, in law, an oath taken on the admittance of any tenant, to be true to the lord of whom he holds his land; by this oath the tenant holds in the freest manner, on account, that all who have fee, hold per fidem et fiduciam, that is, by fealty at the least. This fealty, at the first creation of it, bound the tenant to fidelity, the breach of which was the loss of his fee. It has been divided into general and special; general, that which is to be performed by every subject to his prince; and special, required only of such as, in respect of their fee, are tied by oath to their lords. To all manner of tenures, except tenantcy at will and frank-almoign, fealty is incident, though it chiefly belongs to copyhold estates, held in fee and for life. The form of this oath by stat. 17 Ed. II. is to run as follows. "I, A. B. will be to you my lord D. true and faithful, and bear to you faith for the lands and tenements which I hold of you, and I will truly do and perform the customs and services that I ought to do to you. So help me God."

FEAST, or FESTIVAL, in a religious sense, is a day of feasting and thanksgiving.

The four quarterly feasts, or stated times whereon rent on leases is usually reserved to be paid, are Lady-day, or the annunciation of the blessed virgin Mary, or 25th of March; the nativity of St. John the Baptist, held on the 24th of June, the feast of St. Michael the archangel, on the 29th of September; and Christmas, or rather St. Thomas the apostle, on the 21st of December.

FEATHER, in physiology, a general name for the covering of birds: it being common to all the animals of this class to have their whole body, or at least the greatest part of it, covered with feathers or plumage.

There are two sorts of feathers found on birds, viz. the strong and hard kind, called quills, found on the wings and tail; and the other plumage, or soft feathers, serving for the defence and ornament of the whole body. All birds, so far as yet known, moult the feathers of their whole body yearly. Feathers make a considerable article of commerce, particularly those of the ostrich, heron, swan, peacock, goose, &c. for plumes, ornaments of the head, filling of beds, writing-pens, &c. Geese are plucked in some parts of Great Britain five times in the year; and in cold seasons many of them die by this barbarous custom. Those feathers that are brought from Somersetshire are esteemed the best, and those from Ireland the worst.

Eider down is imported from Denmark; the ducks that supply it being inhabitants of Hudson's-bay, Greenland, Iceland, and Norway. All the islands west of Scotland breed numbers of these birds, which turn out a profitable branch of trade to the poor inhabitants. Hudson's-bay also furnishes very fine feathers, supposed to be of the goose kind. The down of the swan is brought from Dantzic. The same place also sends us great quantities of the feathers of the cock and hen. The London poulterers sell a great quantity of the feathers of those birds, and of ducks and turkeys; those of ducks, being a weaker feather, ar inferior to those of the goose; and turkey's feathers are the worst of any. The best method of curing feathers is to lay them in a room, exposed to the air and sun; and when dried, to put them in bags, and beat them well with poles to get off the dirt.

Feathers, when chemically analysed, seem to possess very nearly the same properties with hair. According to Mr. Hatchett, the quill is composed chiefly of coagulated albumen, without any traces of gelatine. See HAIR.

FEATHER-MILL, in the salt-works, the partition in the middle of the furnace, which it divides into two chambers. See the article SALT-MAKING.

FEATHER-EDGED, among carpenters, an appellation given to planks or boards which have one side thicker than the other.

FECIALES, or FÆCIALES, a college of priests instituted at Rome by Numa, consisting of twenty persons, selected out of the best families. Their business was to be arbitrators of all matters relating to war and peace, and to be the guardians of the public faith. It is probable that they were ranked among the officers of religion, to procure them the more deference and authority, and to render their persons more sacred among the people. If the commonwealth had received any injury from a foreign state, they immediately despatched these officers to demand satisfaction, who, if they could not procure it, were to attest the Gods against the people and country,

and to denounce war: otherwise they confirmed the alliance, or contracted a new one, which they ratified by sacrificing a hog.

FECULA. See GLUTEN.

FEE, in law. All lands in England (the crown-land being in the king's own hands, in right of his crown, excepted) is in the nature of feudum or fee; for though many have land by descent from their ancestors, and others have clearly purchased land with their money, yet is the land of such a nature, that it cannot come to any, either by descent or purchase, but with the burthen that was laid upon him who had novel fee, or first of all received it as a benefit from his lord to him, and to all such to whom it might descend, or any way be conveyed from him; so that in truth, no man has directum dominium, the very property or demesne, in any land, but only the prince in right of his crown. Cam. Brit. 93. See FEODAL SYSTEM.

FEE SIMPLE, is an estate of inheritance whereby a person is seised of lands, tenements, or hereditaments, to hold to him and his heirs for ever, generally, absolutely, and entirely; without mentioning what heirs, but referring that to his own pleasure, or the disposition of the law. It is the most perfect tenure of any, when unincumbered; but although the greatest interest which by our law a subject can possess, yet it may be forfeited for treason or felony. To constitute an estate in fee, or of inheritance, the word heir is necessary in the grant or donation. Co. Lit. 1. Plowd. 498. 2 Black. 48.

FEE QUALIFIED, is such a freehold estate, as has a qualification subjoined to it, and which therefore must determine whenever the qualification is at an end. Co. Lit. 27.

FEE CONDITIONAL. This estate was, at the common law, a fee restrained to some particular heirs, exclusive of others; as to the heirs of a man's body, or to the heirs male of his body: in which cases it was held, that as soon as the grantee had issue born, the estate was thereby converted into fee simple, at least so far as to enable him to sell it, to forfeit it by treason, or to charge it with incumbrances. But the statute de donis having enacted, that such estates so given, to a man and the heirs of his body, should at all events go to the issue, if there were any, or if none, should revert to the donor; this was by the judges denominated an estate in tail. Plowd. 251. See ESTATE.

FEE also signifies a certain allowance to physicians, barristers, attorneys, and other officers, as a reward for their pains and labour. If a person refuse to pay an officer his due fees, the court will grant an attachment against him, to be committed till the fees are paid; and an attorney may bring an action on the case for his fees, against the client that retained him in his cause.

FEE also denotes a settled perquisite of public officers, payable by those who employ them. The fees due to the officers of the custom-house, are expressly mentioned in a schedule, or table, which is hung up in public view in the said office, and in all other places where the said fees are to be paid or received. And if any officer shall offend, by acting contrary to the regulations therein contained, he shall forfeit his office and place, and be for ever after incapable of any office in the custom-house. The other public officers have likewise their settled fees, for the several branches of business transacted in them.

FEE FARM, is when the lord, upon the creation of the tenantcy, reserves to himself and his heirs, either the rent for which it was before let to farm, or at least a fourth part of that farm rent.

FEE FARM RENT, so called, because a farm rent is reserved upon a grant in fee.

FEELERS, in natural history, a name used by some for the horns of insects. See ENTOMOLOGY.

FEELING, one of the five external senses, by which we obtain the ideas of solid, hard, soft, rough, hot, cold, wet, dry, and other tangible qualities.

This sense is the coarsest; but at the same time the surest of all others; it is besides the most universal. We see and hear with small portions of our body, but we feel with all. Nature has bestowed that general sensation wherever there are nerves, and they are every where, where there is life. Was it otherwise, the parts divested of it might be destroyed without our knowledge. It seems on this account nature has provided, that this sensation should not require a particular organization. The structure of the nervous papillæ is not absolutely necessary to it. The lips of a fresh wound, the periosteum, and the tendons, when uncovered, are extremely sensible without them. These nervous extremities serve only to the perfection of feeling, and to diversify sensation. Feeling is the basis of all other sensations.

The object of feeling is every body that has consistency or solidity enough to move the surface of our skin. It was necessary to perfect feeling, that the nerves should form small eminences, because they are more easily moved by the impression of bodies, than an uniform surface. It is by means of this structure, that we are enabled to distinguish not only the size and figure of bodies, their hardness and softness, but also there heat and cold. Feeling is so useful a sensation, that to the blind it supplies the office of eyes, and in some sense indemnifies them for their loss. See PHYSIOLOGY.

FEIGNED ISSUE, is that whereby an action is feigned to be brought by consent of the parties, to determine some disputed right, without the formality of pleading; and thereby to save much time and expense in the decision of a cause. 3 Black. 452.

FELAPTON, in logic, one of the six moods of the third figure of syllogisms, wherein the first proposition is an universal negative, the second an universal affirmative, and the third a particular negative.

FELIS, *cat*, in zoology, a genus of the mammalia class, belonging to the order of feræ. The generic character is: front-teeth six, the intermediate ones equal; grinders three on each side; tongue aculeated backwards; claws retractile.

1. Felis leo, lion. The lion is principally an inhabitant of Africa, but is also found, though far less plentifully, in the hotter regions of Asia. It is, however, in the interior of Africa that he exerts his greatest ravages, and reigns superior among the weaker quadrupeds. A lion of the largest size has been found to measure about eight feet from the nose to the tail, and the tail itself about four feet; the general colour is a pale tawny, still paler or more inclining to white beneath; the head is

very large, the ears rounded, the face covered with short or close hair, the upper part of the head, the neck, and shoulders, coated with long shaggy hair, forming a pendent mane; on the body the hair is short and smooth; the tail is terminated by a tuft of blackish hair. The lioness, which is smaller than the lion, is destitute of the mane, is of a whiter cast beneath. The lion, like the tiger, frequently conceals himself in order to spring on his prey, bounding to the distance of a great many feet, and seizing it with his claws. His strength is prodigious: it has even been affirmed, that a single stroke of his paw is sufficient to break the back of a horse; and that he carries off with ease a middle-sized ox or buffalo. He does not often prey in open sunshine, but commences his depredations at the close of day. The roaring of the lion, when in quest of prey, resembles the sound of distant thunder; and, being re-echoed by the rocks and mountains, appals the whole race of animals, and puts them to sudden flight; but he frequently varies his voice into a hideous scream or yell: he is supposed to be destitute of a fine scent, and to hunt by the eye alone. The lion is commonly said to devour as much as will serve him for two or three days, and when satiated with food, to remain in a state of retirement in his den, which he seldom leaves, except for the purpose of prowling about for his prey. His teeth are so strong, that he breaks the bones with perfect ease, and often swallows them together with the flesh; his tongue, as in other animals of this genus, is furnished with reversed prickles; but they are so large and strong in the lion, as to be capable of lacerating the skin. The lioness is said to bring forth in the spring, in the most sequestered places, and to produce but one brood in the year. The young are four or five in number, which the parent nurses with great assiduity, and attends in their first excursions for prey. When brought into Europe, lions have been known to breed even in a state of confinement; instances of which are recorded by some of the older naturalists. In the Tower of London also, examples of a similar nature have occurred. The young animals are scarcely so large as small pug dogs, and are said to continue at the teat about the space of a year, and to be five years in coming to maturity. If we may judge from some specimens of young lions in the Leverian Museum, which are said to have been whelped in the Tower, their size seems scarcely to exceed that of a half-grown kitten. Indeed, some of the ancient writers have affirmed, that the young lions are hardly larger than weasels.

The count de Buffon, reasoning from the size and constitution of the lion, and the time required for his arriving at full growth, concludes that he "ought to live about seven times three or four years, or nearly to the age of twenty-five." He adds, that those which have been kept at Paris have lived sixteen or seventeen years. If, however, we might depend on the commonly received accounts of those which have been kept in the Tower of London, we might mention the lion known by the name of Pompey, which is said to have lived no less than 70 years in his state of captivity; and another in the same receptacle, which is reported to have lived 63 years. It must be acknowledged, however, that, from the general constitution of the lion, one would not suppose him to be a very long-lived animal.

Lions have sometimes constituted a part of th esta-blished pomp of royalty in the eastern world. The monarch of Persia, as we are informed by Mr. Bell, in his Travels, had, on days of audience, two large lions chained on each side the passages of the hall of state, being led thither, by proper officers, in chains of gold.

The Romans, struck with the magnificent appearance of these animals, imported them in vast numbers from Africa, for their public spectacles. Quintus Scævola, according to Pliny, was the first in Rome who exhibited a combat of lions; but Sylla the dictator, during his prætorship, exhibited a hundred lions; and after him Pompey the Great exhibited no less than 600 in the grand circus, viz. 315 males, and the rest females; and Cæsar the dictator 400. Pliny also tells us, that the first person in Rome who caused them to be yoked so as to draw a carriage, was Mark Antony, who appeared in the streets in Rome in a chariot drawn by lions, accompanied by his mistress Cytheris, an actress from the theatre; a sight says Pliny, that surpassed in enormity even all the calamities of the times!

In modern times, the lion is said to be often hunted with dogs by the colonists about the Cape of Good Hope, and it is added that twelve or fifteen dogs are sufficient for the purpose. The lion, after being roused, runs for same time, then stops and shakes his mane, as if in defiance of the dogs, who, rushing all at once upon him, soon destroy him; two or three of the pack, however, generally falling victims to the first strokes of his paws. See Plate LVII. Nat. Hist. fig. 200 & 201.

2. Felis tigris, tiger, is a native of the warmer parts of Asia, and is principally found in India and the Indian islands. The species extends, however, as far as China and Chinese Tartary, the lake Ural, and the Altaic mountains. Its colour is a deep tawny, or orange-yellow, the face, throat, and under side of the belly, being nearly white; the whole is traversed by numerous long black stripes, forming a bold and striking contrast with the ground-colour. About the face and breast the stripes are proportionally smaller than on other parts; the tail is annulated with black, and is shorter than the body. There seems to be some variation in the proportion and number of the stripes in different individuals; and the ground-colour is more or less bright, according to various circumstances of age and health in the respective animals. Linnæus calls the tiger "*pulcherrimus quadrupedum*." We must not judge of the elegance of this animal's robe from the specimens which are sometimes seen in museums, or even from such living ones as by long confinement, and an alteration of climate, have lost the native brilliancy of their colours. When seen in perfection, and before its health has been impaired by confinement, it is scarcely possible to conceive a more elegantly variegated animal than the tiger: the bright and intense orange-yellow which constitutes the ground colour; the deep and well-defined stripes of black, in some parts double, in others single; the pure white of the cheeks and lower part of the sides, over which a part of the black striping is continued; form all together an appearance far superior in beauty to the skin of the zebra, or that of any other regularly marked quadruped, not excepting even the panther itself.

In its general size the tiger is inferior only to the lion, and has been seen even larger, viz. of the length

of 15 feet from the nose to the tip of the tail. The largest are those of India, and are termed royal tigers; but this distinction is supposed to relate merely to the size of the animal, there being only one species of tiger, though there may perhaps be some races larger than others.

Of so fierce and sanguinary a disposition is the tiger, as to surpass in rapacity every other wild beast, and it is therefore considered as the most dreadful scourge of the hotter regions of Asia. The lion is commonly supposed to prey in a less malignant and cruel manner. He is also, when taken into a state of confinement, capable of being tamed, and rendered mild and placid to his keepers; but the tiger is not to be divested of his natural ferocity of character, and in confinement he generally exhibits all the symptoms of malignity. His method of seizing his prey is by concealing himself from view, and springing with a horrible roar on his victim, which he carries off and tears in pieces, after having first sucked out the blood. The voice of the tiger, in the act of springing on his prey, is said to be hideous beyond conception. Even a buffalo has been thus seized by a tiger, and carried off with as much seeming ease, as to appear scarcely an impediment to the animal's flight. It is affirmed, that if the tiger happens to miss his aim, he does not pursue his prey, but, as if ashamed of his disappointment, runs off. In the beginning of the last century (says Mr. Pennant), a company, seated under the shade of some trees near the banks of a river in Bengal, were surprised by the unexpected sight of a tiger preparing for its fatal spring; when a lady, with almost unexampled presence of mind, furled a large umbrella in the animal's face, which instantly retired, and thus gave an opportunity of escaping from so terrible a neighbour. Another party had not the same good fortune; but in the height of their entertainment lost in an instant one of their companions, who was seized and carried off by a tiger. But the fatal accident which occurred in 1792, in the East Indies, must be still fresh in the memory of all who have read the dreadful description given by an eye-witness of the scene. "We went (says the narrator) on shore on Sangar island to shoot deer, of which we saw innumerable traces, as well as of tigers; notwithstanding which we continued our diversion till near three o'clock, when, sitting down by the side of a jungle to refresh ourselves, a roar like thunder was heard, and an immense tiger seized on our unfortunate friend Mr. Monro, son of sir Hector Monro, and rushed again into the jungle, dragging him through the thickest bushes and trees, every thing giving way to his monstrous strength: a tigress accompanied his progress. The united agonies of horror, regret, and fear, rushed at once upon us. I fired on the tiger: he seemed agitated. My companion fired also; and in a few moments after this, our unfortunate friend came up to us, bathed in blood. Every medical assistance was vain, and he expired in the space of 24 hours, having received such deep wounds from the teeth and claws of the animal as rendered his recovery hopeless. A large fire, consisting of 10 or 12 whole trees, was blazing by us at the time this accident took place, and ten or more of the natives were with us. The human mind can scarcely form any idea of this scene of horror. We had hardly pushed our boat from that accursed shore, when the tigress made her appearance, almost raging mad, and remained on the sand all the while we continued in sight."

The tiger has been known to attack even a lion, and both animals have perished in the conflict. The tigress, like the lioness, produces four or five young at a litter: she is at all times furious, but her rage rises to the utmost extremity when robbed of her young. She then braves every danger, and pursues her plunderers, who are often obliged to release one in order to retard her motion. She stops, takes it up, and carries it to the nearest cover, but instantly returns, and renews her pursuit, even to the very gates of buildings or the edge of the sea; and when her hope of recovering them is lost, she expresses her agony by hideous howlings, which excite terror wherever they reach. See Plate LX. Nat. Hist. fig. 204.

3. Felis pardus, panther. Next to the tiger, the panther is the most conspicuous species in this genus, measuring about six feet and a half, and sometimes nearly seven feet from nose to tail, which is itself about three feet long. The colour of the panther is a bright and beautiful tawny yellow, thickly marked all over the upper parts of the body, shoulders, and thighs, with roundish black spots, disposed into circles, consisting of four or five separate spots; and there is commonly, but not always, a central spot in each circle, in which particular, as well as in its superior size and deeper colour, the panther differs from the leopard, which has very rarely any central spots in its circular markings. On the face and legs the spots are single, and along the top of the back is a row of oblong spots, which are still longer as they approach the tail. The breast and belly are white; the former marked with transverse dusky stripes, the latter and the tail with large irregular black spots.

The panther is principally found in Africa, and is to that country what the tiger is to Asia, with this alleviating circumstance, that it is supposed to prefer the destruction of other animals to that of man. Its manner of seizing its prey resembles that of the tiger, lurking near the sides of woods, &c. and darting forward with a sudden spring. It is of a highly ferocious nature, and scarcely to be tamed. These animals and the leopard were the varii and pardi of the ancients; and one would think (says Mr. Pennant) that the Romans would have exhausted the deserts of Africa by the numbers they drew thence for their public spectacles. Scaurus exhibited at one time 150 panthers; Pompey the Great, 410; and Augustus, 420. It has been doubted whether the panther and the leopard were natives of America as well as of the old continent; but this question seems now to be decided in the negative.

4. Felis leopardus, the leopard, is best distinguished from the panther by its paler yellow colour, its smaller size, and the somewhat closer disposition of the spots which form its ocellated markings; but to a mere general observer, the two animals are so extremely alike as to be frequently mistaken for each other. A true distinctive mark between the leopard and panther is by no means easy to communicate either by description or even by figure. The principal difference is in size, the leopard being considerably the smallest of the two: the colour of the panther is richer or more fulvous than that

of the leopard; but this too is liable to a degree of uncertainty: the ocelli or rounded marks on the panther are larger and more distinctly formed; but the character given by Mr. Pennant of the panther, viz. a central spot in the middle of each, is by no means a permanent or truly distinctive mark; since the spots in some specimens (perhaps the males) are quite plain in the middle; while, in some specimens of the leopard, one or more central spots are visible. As to the subtransverse marks about the neck or breast, they seem to be full as distinct in the leopard at in the panther, and perhaps, upon the whole, we must be content with distinguishing the two species by the size, and by the fulvous yellow of the panther, and the clearer or paler yellow of the leopard. The general length of this species from nose to tail, is four feet, of the tail two and a half. It is a native of Senegal and Guinea, as well as of many other parts of Africa: it also occurs in several parts of Asia, viz. in Persia, India, China, &c. In its manners it resembles the panther.

A variety of this species, of a dusky black, marked with spots of a deeper or more glossy black, and perfectly resembling in disposition those of the common leopard, is found in Bengal. In one of this kind taken to England some years ago, the fur, when a little turned aside, exhibited a slight tinge of the natural or general colour.

5. Felis jubata, the hunting leopard, is about the size of a large greyhound, and of a long make, with narrow chest, and long legs. It is a native of India, where it is said to be tamed, and used for the chase of antelopes and other animals; being carried into the field chained and hooded, and at the proper time loosed; when it is said to steal along the ground at first, concealing itself till it gains a proper advantage, and then to dart on the animal it pursues with several repeated springs. If it happens to miss its prey, it returns to the call of its master.

6. Felis uncia, the ounce, is scarcely inferior in size to the leopard. Its colour is dull white, with a slight yellowish or tawney cast, and the whole is scattered over with differently-sized spots and markings of black. About the head these spots are small, numerous, and roundish; along the back they form a kind of abrupt or irregularly interrupted stripes, while on the sides and limbs they are variously shaped, forming in some places angular and in others somewhat round or oval marks, with a central space included, and on the legs and tail they are black and scattered. In its general form the animal seems much allied to the leopard. It seems not to have been distinctly described by any modern author till the time of Buffon; but it is supposed to have been known to the ancients, and to have been the smaller panther of Oppian, and the panthera of Pliny. It is a native of several parts of Africa and Asia.

7. Felis onca, the Brasilian tiger, is a native of the hotter parts of South America, and is considered as a very fierce and destructive animal. Its manners are said to resemble those of the tiger, lying in ambush for its prey. See Plate LV. Nat. Hist. fig. 198. It is about the size of a wolf, or even larger. Its ground-colour is a pale brownish-yellow, variegated on the upper parts with streaks and open oblong spots or markings of black, the top of the back being marked with long interrupted stripes, and the sides with rows of regular open marks; the thighs and legs are also variegated with black spots, but without central spaces; the breast and belly are whitish; the tail not so long as the body; the upper part marked with large black spots in an irregular manner, the lower with smaller spots.

8. Felis pardalis, ocelot. The ocelot or pardalis is certainly one of the most beautiful of the present genus. In size it is almost equal to the jaguar. Mr. Pennant describes it as about four times the size of a large cat. The ground-colour of the male is a bright reddish-tawny above, nearly white on the lower part of the sides, breast, limbs, and belly. Several large, long, and variously inflected broad stripes, of a deeper or richer tinge than the ground-colour, are disposed over the upper parts of the body: these stripes are edged with black, and have also several differently-shaped black spots in the middle part. The head is streaked and spotted with black, and the upper as well as under parts of the limbs and the belly marked in a beautiful manner with small and numerous round spots; the tail is patched or spotted also. The colours of the female are less vivid, and more inclining to ash-colour. This is an extremely ferocious animal, and inhabits the hotter parts of South America, where it is said to commit great ravages among cattle, &c. It is also said to be untameable in a state of captivity. See Plate Nat. Hist. fig. 203.

9. Felis puma. The puma is the largest of the American beasts of prey, measuring five feet or more from nose to tail, the tail itself about two feet eight inches. It is a long-bodied animal, and stands high on its legs. Its colour is a pale brownish-red, with a slight dusky cast on some parts; the chin is white; the breast and belly ash-coloured; and the insides of the legs are of the same colour; the tail of a dusky-ferruginous tinge, with a black tip. It is a native of many parts of America, both north and south, occurring from Canada to Brasil. The puma is an animal of great strength and fierceness, preying on cattle, deer, &c. Sometimes it is said to climb trees, and watch the opportunity of springing on such animals as happen to pass beneath.

10. Felis discolor, black tiger. This, like the former species, is a native of America, and is considered as a very destructive and ferocious animal. It is about the size of a large dog, and is entirely of a deep brownish-black colour on the upper parts, and pale-grey or whitish beneath; the upper lip and the paws are also whitish; the tail is of the same colour with the body. See Plate Nat. Hist. fig. 205.

11. Felis tigrina, margay. The margay is a native of South America, and is about the size of a common cat. The ground-colour is a bright tawny; the face striped downwards with black; the shoulders and body marked both with stripes and large oblong black spots; on the legs the spots are small; the breast, belly, and insides of the limbs, are whitish; the tail is long, and marked with black, grey, and fulvous. It resides principally on trees, preying on birds: it is said to breed in the hollows of trees, and to bring but two young at a birth. It is very fierce and untamable.

12. Felis capensis, the Cape cat, inhabits the neighbourhood of the Cape of Good Hope, and is described

in the Philosophical Transactions, vol. 71, by Dr. Forster. In its manner it seems extremely to resemble the common cat, frequenting trees, and preying on the smaller animals. The specimen described by Dr. Forster was not more than nine months old, and had been taken quite young. It was perfectly tame and gentle, and had all the actions and manners of a domestic cat. Dr. Forster imagines it to be the same species with the 'nnussi described by Labat, who calls it a sort of wild cat of the size of a dog, with a coat striped and varied like that of a tiger. The length of a skin measured by Mr. Pennant was near three feet from nose to tail; but Dr. Forster's specimen seems to have been much smaller.

13. Felis manul. This species inhabits the middle part of northern Asia, and was first described by Dr. Pallas. It is of the size of a fox, and is of a strong and robust make. Its colour is tawny, but the crown of the head is speckled with black, and the cheeks are marked by two dusky lines running obliquely from the eyes; the feet are striped obscurely with dark lines; the tail is longer than that of a domestic cat, and is thickly beset with hair, and encircled with ten black rings, of which the three next to the tip are placed so near as almost to touch each other.

14. Felis catus. The cat, in a state of natural wildness, and from which are supposed to have proceeded all the varieties of the domestic cat, is a native of the northern regions of Europe and Asia. In this its natural state it differs in some slight particulars from the domestic animal, having a somewhat shorter tail in proportion, a flatter and larger head, and stronger limbs; and, from an exact anatomical inspection of its inferior parts, it appears that the intestines are somewhat shorter than those of the domestic cat. The colour of the wild cat is commonly a pale yellowish-grey, with dusky stripes and variegations, those on the back running lengthwise, those on the sides transversely and with a curved direction: the tail is annulated with several alternate circles of blackish-brown and dull white; the tip of the nose and the lips are black. Even wild cats, however, appear to differ in their shades of colour in different parts of Europe. Mr. Schreber, in his plate of quadrupeds, figures a specimen of a pretty deep tawny colour, varied with black or deep-brown streaks, so that the animal has very much the appearance of a tiger in miniature; while on another plate he has exhibited one, communicated by Dr. Pallas, of a pale grey with black or dark-brown variegations.

The manners of the wild cat resemble those of the lynx, and several others of this genus, living in woods, and preying on young hares, on birds, and a variety of other animals, which it seizes by surprise. It breeds in the hollo s of trees, and produces about four at a birth. "The wild cat (says Mr. Pennant) may be called the British tiger: it is the fiercest and most destructive beast they have; making dreadful havoc among their poultry, lambs, and kids. It inhabits the most mountainous and woody parts of those islands, living mostly in trees, and feeding only by night. It multiplies as fast as the common cats; and often the females of the latter will quit their domestic mates, and return home pregnant by the former."

The varieties of this animal, in a domestic state, are very numerous: it is either entirely black; black and white; black, fulvous, and white (called the tortoise-shell or Spanish cat); white without any variegation; fulvous and white; dun-colour or tawny, either plain or with deeper stripes; tabby, or of a similar colour to the wild cat, but with much bolder or more vivid variegations; slate-coloured or blue grey (called the Chartreux cat); slate-coloured with very long fur, especially on the neck and tail (the Persian cat); white with hair of a similar length (called the Angora cat); or, lastly, with penciled or tufted ears, like a lynx, which sometimes, though rarely, takes place. Of all the above varieties, the Persian and the Angora are the most remarkable: the latter variety has one eye blue, the other yellow; a particularity which takes place in some specimens of the common white cat. It is also observable, that the white variety of the cat is sometimes perfectly deaf.

The cat, when well educated, possesses qualities which will entitle her to the regard and protection of mankind; and if she does not exhibit the vivid and animated attachment of the dog, she is still of an affectionate and gentle disposition, and grateful to her benefactors.

A singular instance of attachment in the cat is recorded in Mr. Pennant's Account of London. Henry Wriothsly, earl of Southampton, the friend and companion of the earl of Essex in his fatal insurrection, having been confined some time in the Tower, was surprised by a visit from his favourite cat, which, says tradition, reached its master by descending the chimney of his apartment.

No animal, whose habits and manners we have the opportunity of accurately observing, exhibits a greater degree of maternal tenderness than the cat. The extreme assiduity with which she attends her young, and the fondness which she shows for them, afford the most pleasing entertainment to a philosophic observer. She even possesses a propensity to nurse with tenderness the young of a different individual; and it is a general observation, that a domestic cat will commonly suckle and nurse any young kitten that is newly introduced to her.

Nothing can be more beautiful than the experiment of setting a young cat, for the first time, before a looking-glass. The animal appears surprised and pleased with the resemblance, and makes several attempts at touching its new acquaintance; and at length, finding its efforts fruitless, it looks behind the glass, and appears highly surprised at the absence of the figure: it again views itself, tries to touch with its foot, suddenly looking at intervals behind the glass. It then becomes more accurate in its observations, and begins, as it were, to make experiments, by stretching out its hand in different directions; and when it finds that these motions are answered in every respect by the figure in the glass, it seems at length to be convinced of the real nature of the image. The same is the case with the dog at an early age.

The cat generally lives in habits of friendship with the other domestic animals; the contrary instances arising entirely from neglect of early education.

The fur of the cat, being generally clean and dry, readily yields electric sparks when rubbed; and if a clean and perfectly dry domestic cat is placed, in frosty

weather, on a stool with glass feet, or insulated by any other means, and rubbed for a certain space in contact with the wire of a coated vial, it will be effectually charged by this method. See Plate LVII. Nat. Hist. fig. 202.

15. Felis serval. The serval is a native of India and Tibet, and is an extremely fierce and rapacious animal. It resides principally among trees, leaping with great agility from one tree to another, and pursuing birds, &c. This species appears to have been first described by the French academicians in their work entitled Memoires pour servir a l'Histoire des Animaux. The specimen there described measured two feet and a half from the nose to the tail, which was eight inches long. Its shape was thick and strong; its general colour was fox-red or ferruginous, with the throat, abdomen, and insides of the legs, yellow-white; it was spotted almost all over with black, the spots being of a long form on the back, and round on the sides, belly, and legs, where they were proportionally smaller and more numerous. The specimen described and figured in the count de Buffon's Natural History differed only in a very few particulars, so slight as to leave no doubt of the identity of the species. It was excessively fierce and untamable. There is also an American serval, which differs chiefly from the above in being mild and gentle.

16. Felis chaus, is an inhabitant of the woody and marshy tracts that border on the western side of the Caspian Sea, and in the Persian provinces of Ghilan and Masenderan, and is frequent about the mouth of the Kur, the ancient Cyrus. In manners, voice, and food, it agrees with the wild cat. Its general length is about two feet six inches from the nose to the tail; but it has been known to measure three feet: the tail reaches only to the flexure of the legs. The colour of this species is a dusky yellowish-brown; the breast and belly much brighter or more inclining to orange-colour; the tail is tipped with black, and has three obscure black bars at some distance from the tip; and on the inside of the legs, near the bend of the knee, are two dusky bars; the ears are tufted with black hairs.

17. Felis rufa, bay lynx. This species is about twice the size of a large cat, and is a native of North America. Its colour is a bright bay, obscurely marked with small dusky spots; the upper and under lip, throat, and whole under sides of the body and limbs, are white. From beneath each eye three curved blackish stripes pass down the cheeks; the upper part of the inside of the fore legs is marked by two black bars; the upper part of the tail is marked with four or five dusky bars, and that next the tip is black, the ears are sharp-pointed, and tufted with long black hairs. This animal was first described by Guldenstedt. The hair is shorter and smoother than that of the common lynx.

18. Felis caracal. The caracal or Persian lynx is a native both of Asia and Africa; and it is said that in some parts of Persia, it is tamed and made use of in the chace. It is an animal of great strength and fierceness. Dr. Charleton mentions one which killed a hound and tore it in pieces in an instant, notwithstanding the vigorous defence made by the dog. It is used not only in the chace of the smaller quadrupeds, but of the larger kinds of birds, such as herons, cranes, pelicans, &c. which it is said to surprise with great address. When it has seized its prey it lies motionless for some time upon it, holding it in its mouth. The caracal is about the size of a fox, but of a much stronger make; its colour is a pale reddish-brown, whitish beneath; the head is small, the face longish, the ears sharp and slender, of a blackish colour, and terminated by a tuft or pencil of long black hairs.

19. Felis lynx, the common lynx, with some slight varieties as to size and colour, appears to be found in all the colder regions of Europe, Asia, and America, residing in thick woods, and preying on hares, deer, birds, and almost every kind of animal inhabitant. The general size of the lynx is that of a middling dog: the measure given by Mr. Pennant of the skin of a Russian lynx is four feet six inches from head to tail, the tail measuring six inches. But the generality of lynxes seem to be somewhat smaller than this. In colour the lynx varies, but is generally of a pale-grey, with a very slight reddish tinge; the back and whole upper parts are obscurely spotted with small dusky or blackish marks. The throat, breast, and belly, are white; the tail white, with a black tip; the ears tipped with pencils of long black hair. The lynx is said to howl almost in the manner of a wolf. In a state of captivity it seems extremely ferocious, and is not to be tamed. See Plate LVII. Nat. Hist. fig. 199

Felis volans, the flying-cat, an animal supposed to be the same with the flying squirrel.

FELLOES, in fortification, are six pieces of wood, each whereof form a piece of an arch of sixty degrees, and joined altogether by dulleges, make an entire circle; which, with the addition of a nave and twelve spokes, make the wheel of a gun carriage. Their thickness usually is the diameter of the ball of the gun they serve for, and their breadth something more.

FELLOWSHIP, or Company, in arithmetic, is when two or more join their stocks, and trade together, dividing their gain or loss proportionably.

Fellowship is either with or without time. Questions without time, or in the single rule of fellowship, as it is frequently called, are wrought by the following proportion:

As the whole stock, to the whole gain or loss, so is each man's particular stock, to his particular gain or loss.

Example I. A, B, and C, make a joint stock: A puts in 460*l.*, B 510*l.*, and C 480*l.*; they gain 340*l.*; what part of it belongs to each?

In order to the solution of this question, find the total of their joint stock, viz.

A's stock 460*l.* + B's stock 510*l.* + C's stock 480*l.* = 1450*l.* the total stock.

Then 1. To find A's share of the gain, state as follows: If 1450*l.* : 340*l.* :: 460*l.*, which being worked by the rule of three, the answer will be 107*l.* 17*s.* $2\frac{3}{4}$*d.* for A's share of the profit.

2. B's share of the gain, by stating thus: if 1450*l.* : 340*l.* :: 510*l.* and working by the rule of three, will be found to be 119*l.* 11*s.* $8\frac{1}{2}$*d.*

3. C's share will appear 112*l.* 11*s.* $6\frac{1}{4}$*d.* when worked as before, after having stated thus: If 1450*l.* : 340*l.* :: 480*l.*

Example II. Suppose three partners, A, B, and C,

make a joint stock in this manner: A puts in 24*l.*, B 32*l.*, and C 40*l.*, in all 96*l.*, with which they trade, and gain 12*l.*; required each man's true share of that gain? The first operation for A's part of the gain will stand thus:

96*l.* : 12*l.* :: 24*l.* : 3*l.* = A's gain.
96*l.* : 12*l.* :: 32*l.* : 4*l.* = B's gain.
96*l.* : 12*l.* :: 40*l.* : 5*l.* = C's gain.

Proof 3*l.* + 4*l.* + 5*l.* = 12*l.* the whole gain.

That is, if the total of all their particular gains amounts to the whole gain, the work is true; if not, some mistake has been committed.

Fellowship *with time*, usually called the *double rule of fellowship*, because every man's money is to be considered with relation to the time of its continuance in the joint stock. It is worked thus: multiply each man's stock by the respective time he puts it in for, and add all the products; the total of which must be your first number through all the statings; the gain or loss the second, as before; and each man's particular stock, multiplied by its time, the third.

Example I. A put into company 560*l.* for eight months, B 279*l.* for ten months, and C 735*l.* for six months; they gained 1000*l.* What share of it must each have?

For the solution of this question, proceed as follows: A's stock 560*l.* × 8 its time = 4480; B's stock 279*l.* × 10 its time = 2790; C's stock 735*l.* × 6 its time = 4410. Then 4480 + 2790 + 4410 = 11680.

Now, 1. To find A's share of the profit, state thus: If 11680*l.* : 1000*l.* :: 4480*l.* which being worked by the rule of three, the answer will be 383*l.* 11*s.* $2\frac{1}{4}$*d.* for A's share of the gain.

2. For finding B's share state thus: If 11680*l.* : 1000*l.* : : 2790*l.* and working as before directed, the answer will be 238*l.* 17*s.* $3\frac{3}{4}$*d.*

3. To find C's proportion of the gain, say, if 11680*l.* : 1000*l.* : : 4410*l.* then working it by the rule of three, the true amount of his share will appear to be 377*l.* 11*s.* $4\frac{1}{4}$*d.*

FELO DE SE, a felon of himself, is a person who, being of sound mind, and of the age of discretion, voluntarily kills himself: for if a person is insane at the time, it is no crime. But this ought not to be extended so far as the coroner's juries sometimes carry it, who suppose that the very act of self-murder is an evidence of insanity; as if every man who acts contrary to reason had no reason at all; for the same argument would prove every other criminal non compos, as well as the self-murderer. 3 Inst. 54.

All inquisitions of the offence, being in the nature of indictments, ought particularly and certainly to set forth the circumstances of the fact; as the particular manner of the wound, and that it was mortal, &c. and in conclusion add, that the party in such manner murdered himself. 1 Salk. 377.

A felo de se forfeits all chattels real and personal, which he has in his own right; and also all such chattels real whereof he is possessed, either jointly with his wife, or in her right; and also all bonds and other personal things in action, belonging solely to himself; and also all personal things in action and intire chattels in possession, to which he was entitled jointly with another, on any account, except that of merchandize; but it is said that he shall forfeit a moiety only of such joint chattels as may be severed, and nothing at all of what he was possessed of as executor or administrator. Standf. P. C. 188, 189. Plow. 243, 262. 3 Inst. 55.

FELONY, in the general acceptation of law, comprises every species of crime which occasioned at common law the forfeiture of lands or goods. This most frequently happens in those for which a capital punishment either was or is liable to be inflicted; for those felonies which are called clergyble, or to which the benefit of clergy extends, were anciently punished with death in lay or unlearned offenders; though now, by the statute law, that punishment is for the first offence universally remitted.

Felony is always accompanied with an evil intention, and therefore shall not be imputed to a mere mistake or misanimadversion; as where persons break open a door to execute a warrant, which will not justify such a proceeding. But the bare intention to commit a felony is so very criminal, that at the common law it was punishable as felony, where it missed its effect through some accident, which no way lessened the guilt of the offenders; but it seems agreed at this day, that felony shall not be imputed to a bare intention to commit it, yet it is certain that the party may be very severely fined for such an intention. 1 Haw. 65.

The punishment of a person for felony, by our ancient books, is, 1st, to lose his life; 2dly, to lose his blood, as to his ancestry, and so to have neither heir nor posterity; 3dly, to lose his goods; 4thly, to lose his lands, and the king shall have year, day, and waste, to the intent that his wife and children be cast out of the house, his house pulled down, and all that he had for his comfort and delight destroyed. 4 Rep. 124. A felony by statute incidentally implies, that the offender shall be subject to the like attainder and forfeiture, &c. as is incident to a felon at common law. 3 Inst. 47. See Burglary, Forgery, Homicide, Petit Treason, Rape, Robbery, &c.

Felon's goods are not forfeited till it is found by indictment that he fled for the felony, and therefore they cannot be claimed by prescription. See Estrays, and Waifs.

Felony *under colour of law:* such is coming into a house by colour of writ of execution, and carrying away the goods. A special trust prevents the felony, until such special trust is determined. 8 Mod. 76.

FELT, in commerce, a sort of stuff, deriving all its consistence merely from being fulled or wrought with lees and size, without either spinning or weaving. Felt is made either of wool alone, or of wool and hair.

FELSPAR. See Lepidolite.

FELUCCA, in sea affairs, a little vessel with six oars, frequent in the Mediterranean, which has this peculiarity, that its helm may be applied either in the head or stern as occasion requires.

FEME covert, a married woman, so called from being under the cover, protection, and influence of her husband. See Husband and Wife.

Feme sole, a single or unmarried woman. A feme sole is liable to perform parish offices, the act only requiring the person to be a substantial householder, without reference to sex.

Feme sole trader, a married woman, who, by the custom of London, trades on her own account, independant of her husband. See Bankruptcy.

FEMININE, or Fœminine, in grammar, one of the genders of nouns.

FEMUR, *os femoris*, the thigh-bone. See Anatomy.

FEN, a place overflowed with water, or abounding with bogs. See Draining.

Fens are either made up of a congeries of bogs, or consist of a multitude of pools or lakes with dry spots of land intermixed, like so many little islands.

Several statutes have been made for the draining of fens, chiefly in Kent, Cambridgeshire, Bedfordshire, Lincolnshire; by 11 Geo. II. commissioners shall be appointed for the effectually draining and preserving of the fens in the isle of Ely, who are authorised to make drains, dams, and proper works thereon; and they may charge the landholders therein with a yearly acre-tax, and in default of payment sell the defaulters' lands.

FENCE, in country affairs, a hedge, wall, ditch, bank, or other inclosure, made around gardens, woods, cornfields, &c. See Husbandry.

Where a hedge and ditch join together, in whose ground or side the ditch is, to the owner of that land belongs the keeping of the same hedge or fence, and the ditch belonging to it on the other side, in repair and scoured. P. Off. 188.

An action on the case or trespass lies for not repairing fences, whereby cattle come into the ground of another, and so damage it. Also it is presentable in the court baron. 1 Salk. 335.

Fence month, a month wherein it is unlawful to hunt in the forest, because the female deer fawn in that time: it being always, according to the charter of the forest, 15 days before, and ending 15 days after Midsummer.

FENCING, the art of making a dexterous use of the sword, as well for attacking an enemy, as for defending one's self.

FEND, in the sea language, imports the same as defend: thus, fending the boat is saving it from being dashed to pieces against the rock, shore, and ship's side. And hence,

FENDERS are pieces of old hawsers, cable-ropes, or billets of wood, hung over the ship's sides, to keep other ships from rubbing against and injuring her.

FENDUE *en pal*, in heraldry, a cross cloven down in pale, that is, from top to bottom, and the two parts set at some distance from each other.

FENESTRA, in anatomy, a term applied to two openings or foramina within the ear, distinguished by the names of the oval and the round fenestra. The fenestra ovalis leads to the vestibule, on which stands the stapes. The fenestra rotunda leads to the cochlea, and is closed by a membrane.

FENNEL. See Anethum.

FENS. Any person convicted of maliciously cutting or destroying any bank, mill, engine, floodgate, or sluice for draining fens, shall be guilty of felony, without benefit of clergy. 27 Geo. II. c. 19.

FEODEL system, the constitution of fiefs or euds. It is about twelve centuries ago since this systen was so universally received in Europe, that sir Henry Spelman calls it the law of nations in our western world. Hence it deserves our attention in a particular manner; a knowledge of the different feuds being indispensably resquisite for a proper understanding either of the civil government of our country, or the laws by which its landed property is regulated.

The military policy of the Celtic or northern nations, known by the names of Goths, Vandals, Franks, Huns, and Lombards, furnished the original constitution or system of feuds. These people pouring out in vast multitudes from the officina gentium or store-house of nations, overran all the European nations on the decline of the Roman empire. They brought the feudal system along with them from the countries out of which they emigrated; and supposing it to be the most proper method of securing their new conquests, they introduced it into their more southerly colonies.

According to this system, the victorious general allotted considerable tracts of land to his principal officers; while they, in like manner, divided their possessions among the inferior officers, and even those common soldiers who were thought to be the most deserving. Allotments of this kind were named feoda, fiefs, fees, or feuds, form a combination of words, in the language of these barbarians, signifying a reward or stipend bestowed on certain conditions. The condition upon which these rewards were given was, that the possessors should faithfully serve the person from whom they were received, both at home and abroad, in a military capacity. To this they engaged themselves by a juramentum fidelitatis, or oath of fealty; in the event of a breach of which, either by not performing the service agreed upon, by deserting their lord in time of battle, &c. the lands were to return to their original possessor.

Thus the possessors of feodal allotments became interested in the defence of them; and not only the receivers, but those who gave them, were equally and mutually bound to defend their possessions, none of them being able to pretend any right but that of conquest. For this purpose, government and subordination were absolutely necessary; it being impossible to conduct any system of defence where every thing was tumultuous and irregular. Every person, therefore, who was a feudatory, *i. e.* who had received lands, was bound to do every thing in his power to defend the lord of his fee; while, on the other hand, the latter was no less subordinate to his immediate superior; and so in succession to the prince himself. In like manner a reciprocal bond of defence existed down from the prince to the lowest feodists.

Such were the foundations on which the feodal system was properly established; and the natural consequence was, a military subjection throughout the whole community. The prince could always collect an army of feudatories ready to defend not only the kingdom in general, but the particular possessions of each person; and the propriety of this constitution was soon apparent in the strength which these newly-erected kingdoms acquired, and the valour with which their conquests were defended.

Besides these feodal grants, however, which were held only on the terms of military service, there were others called allodial, which were given upon more enlarged

principles. To these every free man had a title, and could not only claim his territory as well as the rest, but dispose of it at his pleasure; and this freedom was denominated allodiality. These allodials, however, were not exempted from military service. A part of their freedom consisted in liberty to go to the wars; for this, in the barbarous times we speak of, was the only way to acquire any degree of renown. Only the slaves were destined to follow the arts of peace; while every free person was not only at liberty to defend his country, but under an obligation to do it in case of any urgent necessity.

Thus there was a feodal and a national militia. The free people only were allowed to possess property; the feudal vassals constituted the army, properly so called; while the national militia was composed of the allodial proprietors. This allodiality, however, was not confined to landed property, but included likewise moveable estates or money; so that proprietors of the latter kind were obliged also in times of danger to bear arms and appear in the field. Between the feodal and allodial proprietors, however, there was this farther difference, that the latter had no concern with any private quarrels which might take place among the lords themselves; so that they were never obliged to appear in the field unless when called forth by the sovereign against the enemies of the nation at large. This circumstance we might suppose to be an advantage, but it ultimately operated otherwise; becoming the means of changing the allodial right into a feodal tenure. For some time the holders of fiefs had an eminent advantage over the allodial proprietors. This was owing to the imperfection of government in those days; so that the nobles had it in their power to revenge their own quarrels, while the weak were equally exposed to the insults of both parties. The lord and his vassals, therefore, were always formidable; but the allodial proprietors had scarcely any means of defending themselves. The reason of this was, in the first place, that the law did not allow them to commit any hostilities; and in the next, they were too distant and unconnected to form any proper league for mutual defence; and hence proceeded the necessity already hinted at, of converting allodial property into feudal tenure. This was indeed owing in a great measure to the absurdity and violence of the times, by which gifts of property, burthened with service, and which might return to the person who granted them, were rendered superior in value to the absolute and unconditional possession of a subject. Other considerations, however, contributed to produce the same effect. As in those dark ages no right existed but what had its origin in conquest, it thence followed that the greatest conqueror or warrior was the most honourable person. The king, in whom the whole exploits of the community centred, as being their head, was the most honourable person; and all others derived from him that portion of honour which they enjoyed, and which was most nicely adjusted in proportion as they approached him. Allodial proprietors, therefore, having no pretensions of this kind, were treated with contempt. From this disagreeable situation they wished to free themselves, by converting their allodial property into feudal tenures; while the princes, supposing it their interest to extend those tenures as much as possible, discouraged the allodial possessions. As the feodists supported the importance of the nation and dignity of the monarch, it was not thought proper to allow the allodial proprietors any greater compensations than what were given to vassals in similar cases. Thus they were exposed to continual mortifications in the courts of justice; they were neglected by the king; denied sufficient protection from the laws; exposed not only to continual insults, but to have their property on all occasions destroyed by the great; so that they were without resource except from the feodal tenures, and were obliged even to solicit the privileges which were bestowed in other cases on vassals. In these unhappy circumstances, they were glad to yield up their lands to any superior whom they thought most agreeable, and to receive them back from him as a feudal gift. Thus the landed property was every where changed into feudal tenures, and fiefs became universal.

For some time the feodal system was not only useful in itself, but honourable in its principles; but this continued no longer than while the importers of it into Europe adhered to their original simple and noble maxims. During that period, the lord exercised his bounty to the vassal, which the latter repaid by acts of gratitude; so that the intercourse betwixt them was of the most tender and affectionate kind; and this gave rise to what are called the feodal incidents.

The expectants of fiefs were educated in the hall of the superior, while the tenures were precarious or only for life: and even when they became hereditary, the lord took care of the son and estate of his deceased vassal, not only protecting his person, but taking charge of his education, and directing the management of his affairs. He took pleasure in observing his approach to maturity; and when he came of age, never failed to deliver to him the lands, with the care of which he had been entrusted, and which he had been careful to improve. This was called the incident of wardship.

The incident of relief was founded upon the gratitude of the vassal, who, upon entering on his fief, brought a present to his lord, as an acknowledgment of his care of him during the early part of his life, and in order to conciliate his future regard.

The incident of marriage proceeded also upon the principal of gratitude on the part of the vassal. The latter, conscious of the favours he had received, did not choose to ally himself with a family inimical to his chief; while the superior himself, ambitious to aggrandise and augment the importance of his family, sought how to find the most advantageous match for his vassal.

Sometimes the superior himself was reduced in his circumstances by war or other accidents; but from whatever cause his distress proceeded, even though it had arisen from his own extravagance or prodigality, or when only destitute of means to support his ambition or grandeur, his vassals were bound to support and relieve him according to their circumstances; and this was called the incident of aid.

The incident of escheat took place on the part of the vassal, when, through cowardice, treachery, or any remarkable misbehaviour, he rendered himself unworthy of his fief. In that case, the taking it from him, and giving it to one more worthy, was called an escheat.

While the lords and vassals thus vied with one another in mutual acts of friendship and benevolence, happiness, liberty, and activity, were diffused through the society. The vassals behaved courteously towards the retainers, who were immediately below them; while they again were courted by the lords, as constituting their importance and strength: the lords, lastly, giving a like importance and dignity to the sovereign himself. Thus a regular, powerful, and compact system of government took place, an unanimity and attention pervaded the various departments of state; so that while the subjects were free, the nation at large was formidable.

During this state of affairs, the members of the national assembly in every country of Europe appeared there in arms, whether they came personally or by their representatives. Such particularly was the case under the Anglo-Saxon government; and the happiness they at that time enjoyed made the oppression and tyranny of the Normans appear the more intolerable. In process of time, however, the state of society began to suffer a remarkable alteration. The high and disinterested notions from which the happiness above-mentioned took its origin, declined; the romantic ideas of chivalry ceased; and much more interested notions of property came in their stead. The separation of the interests of the lords from their vassals was the first step towards the destruction of the feodal system. Thus the incidents, which, as has just now been mentioned, promoted their happiness, did the very reverse. Property, being now looked upon as a distinction superior to personal merit, naturally introduced the most mercenary views. In consequence of these, the infant ward, the care of whom was wont to be considered as a sacred and honorary trust, was now only looked upon as a means of procuring emolument to the superior. The latter now regarded the profits of his vassals as so many diminutions of his own wealth. Instead of taking care to improve the estate of his ward as formerly, he impoverished it; not only neglecting the education of the heir, but offering insults to himself; insomuch that the relations of the unfortunate vassal were frequently obliged to ransom from the avaricious superior both his person and effects. By merchandise of this kind the coffers of princes were filled, and wardships let out to strangers, who might exercise their rapacity with greater freedom. When the vassal at last attained the years of maturity, he came to the possession of his lands without any of that joy and festivity which usually took place on the occasion. He received an inheritance wasted and destroyed, while new grievances daily presented themselves to augment the horrors of his situation. All the incidents, which in former times were so many expressions of gratitude on the part of the vassal, were now changed into taxes which might be exacted at the pleasure of the lord. Before the vassal was invested in his land, the superior exacted from him a certain sum or other gift, to be measured only by his own rapacity; and in case of delay or inability to pay this demand, the superior continued in possession of the estate. Such scandalous oppression could not but produce the greatest discontent and clamour. Applications were made to the law without success; nor were even the laws regarded which were fabricated on purpose for their relief. The incident of marriage now proved a source of the most dreadful oppression. The lord assumed a right of marrying his vassal to whom he pleased; and he not only exerted this right himself, but would sell it to a stranger, or allow the vassal to buy it himself; while the penalty annexed to a marriage without the consent of the superior involved no less punishment than the loss of the estate itself, or some grievous infliction as for a crime of the first magnitude. The case was still worse with a female ward, whose beauty and accomplishments became a source of gain to the superior, or were sacrificed to please his whim or caprice; so that her relations were frequently obliged to buy from him the privilege of marrying her to the person she or they thought most proper. In like manner the aid, which was formerly a voluntary gift from the vassal in cases of distress happening to his lord, now became an unavoidable tax. An aid formerly was demanded, when the eldest daughter of the superior was married, when his eldest son was knighted, or when the superior himself was taken prisoner in battle. These were the only legal causes of making a demand of this kind; but, in the subsequent times of degeneracy, the most frivolous pretences were every day made use of by the prince to oppress the lords, and by the lords to oppress their vassals; demanding subsidies at pleasure, which their inferiors were always obliged to comply with. Lastly, the escheat, which in former times took place only in cases of cowardice, treachery, or some other heinous crime, was now inflicted on the most trifling occasions. If the vassal happened to be too long in attending the court of his superior to take the oath of fealty; if he committed any action which could in the least be construed an infringement of the oath; if he neglected to give his lord warning of any misfortune which he might suppose was about to befal him; revealed any thing concerning him; made love to his sister or daughter, &c.; or even if he should grant a tenure of land to another person in form different from that in which he held his own; all these, nay others still more ridiculous, were judged sufficient reasons for the superior to seize on the estate of the vassal, and involve him and his family in ruin.

Notwithstanding these oppressions, however, the vassal was still obliged to submit to his lord, to own him as his superior, and even in appearance to pay him the same respect as formerly, when the greatest unanimity and cordial affection subsisted between them. Still he was obliged to perform the same military service; because a failure in that respect would have subjected him to a forfeiture of lands according to the original agreement. A vast difference, however, now took place in the valour and activity which inspired the army. The vassals, forced into the field with desponding hearts, were indifferent as to the success of the cause in which they were engaged, and frequently obstructed instead of forwarding the operations of the field. Hence the sovereign found himself embarrassed; and, though nominally at the head of a martial and powerful people, was frequently unable to effect any thing on account of the mutual hatred and dissension which every where prevailed.

Thus the feodal states of Europe became unnaturally weak; a remedy was necessary; and it is remarkable, that the same remedy was applied all over the continent. This was, in short, the making fiefs hereditary, which

till now had only been granted for a long term of years; and, in return, burdening the lands with a certain number of soldiers, which were not to be refused on any pretence whatever. Hence was derived the tenure of knight-service. A certain portion of land, burdened with the service of one horse-soldier or knight, was called a knight's fee; and thus an estate, furnishing any number of soldiers, was said to contain as many knight's fees; so that now the manors, baronies, &c. become powerful according to the number of soldiers they were bound to furnish. In the grants from the crown, the nobility were obliged to furnish a certain number of soldiers for the service of the sovereign; and in those from the nobility to their vassals the like service was required. Even the commons who had grants from the crown furnished a certain proportion of knights or cavalry. The force of the nation was called into action by grants in capite, or from the sovereign and nobility. A numerous and powerful army was instantly assembled, and at once ready for action. Of this army the king was the general, the nobility were the officers, and the vassals soldiers, the whole being exactly arranged, and capable of entering upon any expedition without the least delay.

Thus a remedy was found in some measure for the weakness of the feodal sovereigns; but, though the knight's-tenure could accomplish this, it could not bring back the former affection and cordiality which subsisted between the various ranks of people. On the contrary, by uniting them more firmly to one another by legal ties, it rendered matters rather worse. The oppression originating from the operation of the feodal incidents still continued with unremitting violence. The grants of knight's-tenure were attended with the same oaths of homage and fealty; the same incidents of relief, wardship, marriage, aid, and escheat; with the feodal tenures. The princes promised to abate somewhat of their rigour in demanding the feodal perquisites, but did not keep their word. Laws were occasionally promulgated, and for some time had an effect; but palliatives soon became ineffectual, and a new state of weakness commenced.

The two remarkable eras in the feodal history are, the time before the invention of knight's-service, and that during which it continued. Fiefs were in a state of fluctuation from the destruction of the Roman empire till the ninth century; but they were rendered perpetual in France about the year 877, and were generally become so in every country in Europe about the beginning of the tenth. Du Cange, *voce Militia*, gives us an example of a knight's fee in the year 880. By the year 987, when Hugh Capet was raised to the throne of France, knight-service was become general all over Europe, and was introduced into England, after having made its appearance in other countries. In England, however, there have been several doubts and difficulties among the learned concerning the introduction of the feodal laws. Many are of opinion, that they were first introduced by William the Conqueror, and, consequently, that they were entirely unknown to the Anglo-Saxons: but others think that they existed among the latter in the same form under which they were continued by the Normans. Dr. Stuart is of opinion, that the Saxons who settled in England could not be strangers to fiefs. He supposes the conformity of manners, which undoubtedly prevailed between the Saxons and other barbarians, a sufficient proof that the hereditary grant of land, as well as the fluctuating state of feodal tenures which preceded it were known to the former. Collateral proofs are derived from the spirit and tenure of the Anglo-Saxon laws, but especially from the grants of hereditary estates on condition of military service. The condition of fiefs, however, under the Anglo-Saxons, was very different from what it was afterwards. In their times, we find no mention made of those oppressions of which so much notice has already been taken; and this may easily be accounted for from the alteration of the feodal spirit in different ages. During the time that a warm and generous affection subsisted between the feodal superiors and vassals, the incidents were marks of generosity on the one part and gratitude on the other; but as soon as a variance had taken place, from the interested disposition which the introduction of luxury produced, the same incidents became sources of the most flagrant oppression. This was remarkably the case in the time of William the Conqueror; and during the reign of king John matters were come to such a crisis, that the people every where complained loudly, and demanded the restoration of the laws of Edward the Confessor. "What these laws of Edward the Confessor were (says Mr. Hume) which the English, every reign during a century and a half, desired so passionately to have restored, is much disputed by antiquarians; and our ignorance of them seems one of the greatest defects of the ancient English history." Dr. Stuart has offered an explanation; but this is in fact no more than a conjecture, that "by the laws or customs of the Confessor, that condition of felicity was expressed which had been enjoyed during the fortunate state of the feodal association. The cordiality, equality, and independance, which then prevailed among all ranks in society, continued to be remembered in less prosperous times, and occasioned an ardent desire for the revival of those laws and usages which were the sources of so much happiness."

Besides the great distinction (of which an account has already been given) between the state of fiefs under the Anglo-Saxons and under the Normans, they were no less istinguished by the introduction of knight's-service. Hitherto the refinement of the English had been obstructed by the invasion of the Danes, and the insular situation of the kingdom; but after the Norman conquest the fiefs were made perpetual. Still, however, the knight's-fee and knight's-service were altogether unknown. William, the sixth prince who enjoyed the duchy of Normandy, was well acquainted with every thing relating to fiefs; for that dutchy had experienced all the variety incidental to them, from the time of its being granted to Rollo by Charles the Simple, in the year 912, to the year 1066, when William was put in possession of England by the battle of Hastings.

On his accession to the throne, a number of forfeitures took place among those who had followed the fortunes of Harold. Their estates were to be disposed of at the pleasure of the conqueror; and it was natural to suppose that he would follow the method practised in his own country. Hence the origin of knight's-service in England. A grant of land to any person whatever, was estimated at a certain number of knight's-fees; and each of these required the service of the knight. The grants of

lands were even renewed to the old tenants under this tenure; so that by degrees the whole military people in the kingdom acquiesced in it. To accomplish this, Domesday-book is supposed to have been compiled, which contained an exact account of all the landed property in the kingdom. Hence it is to be concluded, not that William introduced fiefs into England, as some have imagined, but that he brought them to their ultimate state of perfection by the introduction of knight's-service. This is evident from the laws enacted during his reign. In these it is not only mentioned that knight's-service was enacted, but that it was done expressly with the consent of the common council of the nation; which at that time was equivalent to an act of parliament.

The invention of knight's-service proved generally agreeable: for, as few of the Anglo-Saxon fiefs were hereditary, the advancement of the rest to perpetuity, under the tenure of knight's-service, must have been accounted an acquisition of some importance, as not only augmenting the grandeur and dignity of the sovereign, but securing the independence of the subject, and improving his property. In the happy state of the feodal association, there was indeed no necessity for the knight's-fee; but when the discordance and oppression so often mentioned began to take place, it became then necessary to point out particularly every duty of the vassal as well as of the lord; and this was fully done by the invention of knight's-service. The nobles possessed duchies, baronies, and earldoms, which extensive possessions were divided into as many fees, each of them to furnish a knight for the service of the king or of the superior; so that every feodal state could command a numerous army and militia, to support and defend it in case of any emergency. The knights were also bound to assemble in complete armour whenever the superior thought proper to call, and to hold themselves in readiness for action whenever the king or superior found it convenient to take the field; so that thus the militia might be marched at the shortest notice to defend or support the honour of the nation.

The knights were usually armed with an helmet, sword, lance, and shield; and each was besides obliged to keep a horse. This last requisite was owing to the contempt into which the infantry had fallen, through the prevalence of tournaments and luxuries of various kinds, though it was by means of the infantry that the barbarians had originally distinguished themselves in their wars with the Romans, and become able to cope with those celebrated warriors. All proprietors of fees or tenants by knight's-service fought on horseback; the cavalry were distinguished by the name of battle, and the success of every encounter was supposed to depend on them alone. They only were completely armed; the infantry, being furnished by the villages under the jurisdiction of the barons, had at first only bows and slings, though afterwards they were found worthy of much greater attention.

While the feodal association remained in perfection, the superior could at any time command the military service of his vassals; but, in the subsequent degeneracy, this service could neither be depended upon when wanted, nor was it of the same advantage when obtained as formerly. The invention of knight's-service tended in a great degree to remedy this inconvenience. Those who were possessed of knight's-fees were now obliged to remain forty days in the field at their own expense; and this without exception, from the great crown vassals to the smallest feudatories: but if longer service was required, the prince was obliged to pay his troops. In those times, however, when the fate of nations was frequently decided by a single battle, a continuance in the field for 40 days was sufficient for ordinary occasions.

Thus matters seemed once more to be restored nearly to their former state. It was now, as much as ever, the interest of the nation to act with unanimity in its defence, not only against foreign enemies, but against the tyranny of the prince over his subjects, or of one part of the subjects over the other. New inconveniences, however, soon began to take place, owing to the gradual improvements in life and the refinement of manners. From the first institution of military service, a fine had been accepted instead of actual appearance in the field. In the times of barbarity, however, when men accounted rapine and bloodshed their only glory, there were but few who made an offer of this compensation; but as wealth and luxury increased, and the manners of people became softer, a general unwillingness of following the army into the field became also prevalent. A new tenure called *escuage*, was therefore introduced, by which the vassal was only obliged to pay his superior a sum of money annually instead of attending him into the field. Hence originated taxes and their misapplication; for as the king was lord paramount of the whole kingdom; it thence happened that the escuage-money collected throughout the nation centred in him. The princes, then, instead of recruiting their armies, filled their coffers with the money, or dissipated it otherwise, hiring mercenaries to defend their territories when threatened with any danger. These being composed of the dregs of the people, and disbanded at the end of every campaign, filled all Europe with a disorderly banditti, who frequently proved very dangerous to society. To avoid such inconveniences, standing armies were introduced, and taxations began to be raised in every European kingdom. New inconveniences arose. The sovereigns in most of these kingdoms, having acquired the right of taxation, as well as the command of the military power, became completely despotic; but in England the sovereign was deprived of this right by Magna Charta, which was extorted from him, as related in English histories; so that, though allowed to command his armies, he could only pay them by the voluntary contributions of the people, or their submitting to such taxations as were virtually imposed by themselves.

The tenure by knight's-service was continued in Great Britain (nominally at least), with all the incidents, homage, fealty, escuage, wardship, marriage, &c. till the time of the civil wars, when it was abolished by the Long Parliament, and the abolition was confirmed by 12 Car. II. c. 24.

FEOFFMENT, may be defined to be the gift of any corporeal hereditament to another. He that so gives or enfeoffs, is called the feoffor, and the person enfeoffed is denominated the feoffee. 2 Black. 20. But by the mere words of the deed, the feoffment is by no means perfected. There remains a very material ceremony to be performed, called livery of seisin, without which the feoffee has but a mere estate at will. Id.

The end and design of this institution was by this sort

of ceremony or solemnity, to give notice of the translation of the feud from one hand to another; because if the possession might be changed by the private agreement of the parties, such secret contract would make it difficult and uncertain to discover in whom the estate was lodged, and consequently the lord would be at a loss of whom to demand his services, and strangers equally perplexed to discover against whom to commence their actions for the prosecution and recovery of their right. To prevent, therefore, this uncertainty, the ceremony of livery and seisin was instituted. 2 Bac. Abr. 482.

Of the several sorts of livery. The livery in deed is the actual tradition of the land, and is made either by the delivery of a branch of a tree or a turf of the land, or some other thing, in the name of all the lands and tenements contained in the deed; and it may be made by words only, without the delivery of any thing; as if the feoffor upon the land, or at the door of the house, says to the feoffee, "I am content that you should enjoy this land according to the deed." This is a good livery to pass the freehold. Co. Lit. 48. *a.*

The livery within view, or the livery in law, is when the feoffor is not actually on the land or in the house, but being in sight of it, says to the feoffee, "I give you yonder house or land; go and enter into the same, and take possession of it accordingly." This livery in law cannot be given or received by an attorney, but only by the parties themselves. Pollex, 47.

But this sort of livery is not perfect to carry the freehold, till an actual entry made by the feoffee, because the possession is not actually delivered to him, but only a licence or power given him by the feoffor to take possession of it; and therefore if either the feoffor or feoffee dies before livery, and entry made by the feoffee, the livery within the view becomes ineffectual and void; for if the feoffor dies before entry, the feoffee cannot afterwards enter, because then the land immediately descends upon his heir, and consequently no person can take possession of his land without an authority delegated from him who is the proprietor; nor can the heir of the feoffee enter, because he is not the person to whom the feoffor intended to convey his land, nor had he an authority from the feoffor to take the possession: besides, if the heir of the feoffee was admitted to take possession after his father's death, he would come in as a purchaser; whereas he was mentioned in the feoffment to take as the representative of his ancestor, which he cannot do, since the estate was never vested in his ancestor. Co. Lit. 48. b.

A feoffment cannot be made of a thing of which livery cannot be given, as of incorporeal inheritances, such as rent, advowson, common. &c. 2 Rol. 1. *l.* 20.; though it be an advowson, &c. in gross. 21 Id.

A man may either give or receive livery in deed, by letter of attorney; for since a contract is no more than the consent of a man's mind to a thing, where that consent or occurrence appears, it would be most unreasonable to oblige each person to be present at the execution of the contract, since it may as well be performed by any other person delegated for that purpose by the parties to the contract. Co. Lit. 52.

There are few or no persons excluded from exercising this power of delivering seisin; for monks, infants, femes covert, persons attainted, outlawed, excommunicated, villains, aliens, &c. may be attorneys; for this being only a naked authority, the execution of it can be attended with no manner of prejudice to the persons under these incapacities or disabilities, or to any other person who by law may claim any interest of such disabled persons after their death. Co. Lit. 52. *a.* See Fine.

FEOFFOR and Feoffee. Feoffor is he who infeoffs or makes a feoffment to another of lands or tenements in fee simple; and feoffee is the person infeoffed, or to whom the feoffment is made. See Feoffment.

FERÆ, in zoology, an order of quadrupeds, the distinguishing characters of which are, that all the animals belonging to it have fore-teeth conic, usually six in each jaw; tusks longer; grinders with conical projections; feet with claws; claws subulate; food, carcases, and preying on other animals. See Natural History, Zoology, &c.

Feræ naturæ. Animals of a wild nature are those in which a man has not an absolute but only a qualified and limited property, which sometimes subsists, and at other times does not subsist. And this qualified property is obtained either by the art and industry of man, or the impotence of the animals themselves, or by special privilege.

A qualified property may subsist in animals *feræ naturæ*, by the art and industry of man, either by his reclaiming and making them tame, or by so confining them that they cannot escape and use their natural liberty; such as deer in a park, hares or conies in an enclosed warren, doves in a dovehouse, pheasants or partridges in a mew, hawks that are fed and commanded by the owner, and fish in a private pond or in trunks. These are no longer the property of a man than while they continue in his keeping or actual possession; but if at any time they regain their natural liberty, his property instantly ceases, unless they have animum revertendi, which is only to be known by their usual custom of returning.

A man may have a qualified property in animals feræ naturæ, by special privilege; that is, he may have the privilege of hunting, taking, and killing them, in exclusion of other persons: under which head may be considered all those animals which come under the denomination of game. Here a man may have a transient property in these animals, so long as they continue within his liberty, and may restrain any strangers from taking them therein, but the instant they depart into another liberty, this qualified property ceases. 2 Black. 391.

Larceny cannot be committed of things feræ naturæ, while at their natural liberty; but if they are made fit for food, and reduced to tameness, and known by the taker to be so, it may be larceny to take them. 1 Haw. 94. See Game.

FEE de fourchette, in heraldry, a cross having at each end a forked iron, like that formerly used by soldiers to rest their musquets on. It differs from the cross fourché, the ends of which turn forked, whereas this has that sort of fork fixed upon the square end.

FERENTARII, in Roman antiquity, were auxiliary troops, lightly armed; their weapons being a sword, bow, arrows, and a sling.

FERIÆ, in Roman antiquity, holidays, or days upon which they abstained from work.

The Romans had two kinds of feriæ: 1. The public, common to all the people in general. 2. The private, which were only kept by some private families.

The public feriæ were fourfold: 1. Stativæ friæ, holidays which always fell out upon the same day of the month, and were marked in the calendar: of these the chief were the agonalia, carmentalia, and lupercalia. 2. Conceptivæ feriæ, holidays appointed every year upon certain or uncertain days by the magistrates or the pontiff: such were the Latinæ, paganalia, compitalia, &c. 3. Imperativæ feriæ, holidays commanded or appointed by the authority of the consuls or prætors: of this kind we may reckon the lectisternium. 4. Nundinæ, the days for fairs. The private feriæ were either confined to private families or particular persons, as birth-days; and those expiations upon the tenth day after a person died in a house, called feriæ denicales. From this term our word fair seems to be derived.

FERIA, in the Romish breviary, is applied to the several days of the week: thus Monday is the feria secunda, Tuesday the feria tertia, though these days are not working days, but holidays. The occasion of this was, that the first Christians used to keep the Easter-week holy, calling Sunday the prima feria, &c. whence the term feria was given to the days of every week. But besides these, they have extraordinary feriæ, viz. the last three days of passion-week, the two days following Easter-day, and the second feriæ of rogation.

FERMENTATION. During the spontaneous decomposition which vegetable substance undergo, it is obvious that the simple substances of which they are composed must unite together in a different manner from that in which they were formerly united, and form a new set of compounds which did not formerly exist. The specific gravity of these new compounds is almost always less than that of the old body. Some of them usually fly off in the state of gas or vapour. Hence the odour that vegetable bodies emit during the whole time that they are running through the series of their charges. When the odour is very offensive or noxious, the spontaneous decomposition is called putrefaction; but when the odour is not offensive, or when any of the new compounds formed is applied to useful purposes, the spontaneous decomposition is called fermentation. The term is supposed by some to have originated from the intestine motion which is always perceptible while vegetable substances are fermenting; while by others it is derived from the heat which in these cases is always generated. It is now very often applied to all the spontaneous changes which vegetable bodies undergo, without regard to the products. By fermentation, then, are now meant all the spontaneous changes which take place in vegetable substances after they are separated from the living plant. See CHEMISTRY.

Fermentation never takes place unless vegetable substances contain a certain portion of water, and unless they are exposed to a temperature at least above the freezing-point. When dry or freezing, many of them continue long without alteration. Hence we have an obvious method of preventing fermentation.

Sugar, gum, sarcocol, starch, indigo, wax, resins, camphor, caoutchouc, sandaracha, gum-resins, wood, and suber, though mixed with water, and placed in the most favourable temperature, show scarcely any tendency to change their nature. Oils absorb oxygen from the atmosphere, but too slowly to produce any intestine motion. Tan, some of the acids, and extract, are gradually decomposed; the surface of the liquid becomes mouldy, and an insipid sediment falls to the bottom: and when the process has once begun, it proceeds with great rapidity. Albumen and fibrina putrefy very quickly, but the products have not been ascertained; gluten gradually changes into a kind of cheese.

But it is when several of the vegetable principles are mixed together that the fermentation is most perceptible, and the change most remarkable. Thus when gluten is added to a solution of sugar in water, the liquid soon runs into vinegar, or in certain cases to alcohol and vinegar. When gluten is mixed with starch and water, alcohol and vinegar usually make their appearance; but the greatest part of the starch remains unaltered. It has been observed that certain substances are particularly efficacious in exciting fermentation in others. These substances have received the name of ferments.

But the phenomena of fermentation do not appear in their greatest perfection in our artificial mixtures of vegetable principles. Those complicated parts of plants in which various principles are already mixed by nature, especially the liquid parts, exhibit the finest specimens of it; such as the sap of trees, the juices of fruits, the decoctions of leaves, seeds, &c. It is from such natural mixtures that we obtain all the products of fermentation which mankind have applied to useful purposes; such as indigo, beer, bread, vinegar, wine, &c. We shall first treat of the fermentation which takes place during the making of bread; secondly, of the fermentation which produces intoxicating liquors; and thirdly, of the fermentation which produces vinegar. These are usually called the panary, vinous, and acetous fermentations.

FERMENTATION, *panary*. Simple as the manufacture of bread may appear to us who have always been accustomed to consider it as a common process, its discovery was probably the work of ages, and the result of the united efforts of men whose sagacity, had they lived in a more fortunate period of society, would have rendered them the rivals of Aristotle or of Newton.

The method of making bread similar to ours was known in the East at a very early period; but neither the precise time of the discovery, nor the name of the person who published it to the world, has been preserved. We are certain that the Jews were acquainted with it in the time of Moses, for in Exodus (ch. xii. 15.) we find a prohibition to use leavened bread during the celebration of the passover. It does not appear, however, to have been known to Abraham; for we hear, in history, of cakes frequently, but nothing of leaven. Egypt, both from the nature of the soil and the early period at which it was civilized, bids fairest for the discovery of making bread. It can scarcely be doubted that the Jews learned the art from the Egyptians. The Greeks assure us, that they were taught the art of making bread by the god Pan. We learn from Homer that it was known during the Trojan war. The Romans were ignorant of the method of making bread till the year 580 after the building of Rome, or 200 years before the commencement of the Christian æra. Since that period the art has never been unknown in the south of Europe: but it made its way to the north very slowly; and even at present in many northern countries, fermented bread is but very seldom used.

The only substance well adapted for making loaf-

bread, is wheaten flour, which is composed of three ingredients: namely, gluten, starch, and sweet mucous matter, which possesses nearly the properties of sugar, and which is probably a mixture of sugar and mucilage. It is to the gluten that wheat-flour owes its superiority to every other as the basis of bread. Indeed there are only two other substances at present known of which loaf-bread can be made: these are rye and potatoes. The rye loaf is by no means so well raised as the wheat loaf; and potatoes will not make bread at all without particular management. Potatoes, previously boiled and reduced to a very fine tough paste by a rolling-pin, must be mixed with an equal weight of potatoe-starch. This mixture, baked in the usual way, makes a very white, well-raised pleasant bread. We are indebted for the process to Mr. Parmentier. Barley-meal perhaps might be substituted for starch.

The baking of bread consists in mixing wheat-flour with water, and forming it into a paste. The average proportion of these is, two parts of water to three of flour. But this proportion varies considerably, according to the age and quality of the flour. In general, the older and the better the flour is, the greater is the quantity of water required. If the paste, after being thus formed, is allowed to remain for some time, its ingredients gradually act upon each other, and the paste acquires new properties. It gets a disagreeable sour taste, and a quantity of gas (probably carbonic acid gas) is evolved. In short, the paste ferments. These changes do not take place without water: that liquid, therefore, is a necessary agent. The gluten is altered, and probably acts on the starch; for if we examine the paste after it has undergone fermentation, the gluten is no longer to be found. If paste, after standing for a sufficient time to ferment, is baked in the usual way, it forms a loaf full of eyes like our bread, but of a taste so sour and unpleasant, that it cannot be eaten. If a small quantity of this old paste, or leaven as it is called, is mixed with new-made paste, the whole begins to ferment in a short time; a quantity of gas is evolved; but the glutinous part of the flour renders the paste so tough, that the gas cannot escape; it therefore causes the paste to swell in every direction: and if it is now baked into loaves, the immense number of air-bubbles imprisoned in every part renders the bread quite full of eyes, and very light. If the precise quantity of leaven necessary to produce the fermentation, and no more, has been used, the bread is sufficiently light, and has no unpleasant taste; but if too much leaven is employed, the bread has necessarily a bad taste; if too little, the fermentation does not come on, and the bread is too compact and heavy. To make good bread with leaven, therefore, is difficult.

The ancient Gauls had another method of fermenting bread. They formed their paste in the usual way; and, instead of leaven, mixed with it a little of the barm or yeast which collects on the surface of fermenting beer. This mixture produced as complete and as speedy a fermentation as leaven; and it had the great advantage of not being apt to spoil the taste of the bread. About the end of the 17th century, the bakers in Paris began to introduce this practice into their processes. The practice was discovered, and exclaimed against; the faculty of medicine, in 1688, declared it prejudicial to health; and it was not till after a long time that the bakers succeeded in convincing the public that bread baked with barm is superior to bread baked with leaven. In this country the bread has for these many years been fermented with barm.

With respect to the nature of the barm which produces these effects, Mr. Henry of Manchester has proved, by a number of very interesting experiments, that carbonic acid is capable of being employed in many cases with success as a substitute for barm. But the analysis of Mr. Westrum has demonstrated, that the barm which collects on the surface of beer is of a much more complicated nature. That celebrated chemist obtained from 15060 parts of good barm the following substances:

15	carbonic acid
10	acetic acid
45	malic acid
240	alcohol
120	extractive
240	mucilage
315	sugar
480	gluten.
13595	water
15060.	

Besides 69 parts of lime, 13 potass, some saclactic acid, and traces of phosphoric acid and silica.

But all these ingredients are not essential to barm. Westrum ascertained that the extractive, mucilage, sugar, and malic acid, are incable of producing fermentation; that barm, deprived of its gluten by filtration, loses the property of exciting fermentation in beer; that the gluten of wheat is capable alone of exciting a fermentation: and that gluten, mixed with a vegetable acid, answers all the purposes of a ferment. Hence it follows, that these bodies alone are essential to barm. But leaven is precisely such a compound.

After the bread has fermented, and is properly raised, it is put into the oven, which is previously heated, and allowed to remain till it is baked. The mean heat of an oven, as ascertained by Mr. Tillet, is 448. The bakers do not use a thermometer; but they judge that the oven has arrived at the proper heat when flour thrown on the floor of it becomes black very soon without taking fire. We see, from Tillet's experiment, that this happens at 448°.

When the bread is taken out of the oven, it is found to be lighter than when put in, as might naturally have been expected, from the evaporation of moisture which must have taken place at that temperature. Mr. Tillet, and the other commissioners who were appointed to examine this subject, in consequence of a petition from the bakers of Paris, found that a loaf, which weighed, before it was put into the oven, 4.625 lbs., after being taken out baked, weighed, at an average, only 3.813 lbs. or 0.812 lb. less than the paste. Consequently, 100 parts paste lose, at an average, 17.34 parts, or somewhat more than one-fifth, by baking. They found, however, that this loss of weight was by no means uniform, even with respect to those loaves which were in the oven at the same time, of the same form, and in the same place, and which were put in and taken out at the same instant. The greatest difference, in these circumstances, amounted to .2889, or 7.5 parts in the hundred, which is about one thirteenth of the whole.

This difference is very considerable: and it is not easy to say to what it is owing. It is evident, that if the paste has not all the same degree of moisture, and if the barm is not accurately mixed through the whole, if the fermentation of the whole is not precisely the same, that these differences must take place. Now it is needless to observe how difficult it is to perform all this completely. The French commissioners found, as might indeed have been expected, that, other things being equal, the loss of weight sustained is proportional to the extent of surface of the loaf, and to the length of time that it remains in the oven; that is, the smaller the extent of the external surface, or, which is the same thing, the nearer the loaf approaches to a globular figure, the smaller is the loss of weight which it sustains; and the longer it continues in the oven, the greater is the loss of weight which it sustains. Thus a loaf which weighed exactly 4 lbs. when newly taken out of the oven, being replaced as soon as weighed, lost, in ten minutes, .125lb. of its weight; and in ten minutes more it again lost .0625 lb.

Loaves are heaviest when just taken out of the oven; they gradually lose part of their weight, at least if not kept in a damp place, or wrapped round with a wet cloth. Thus Mr. Tillet found that a loaf of 4 lbs. after being kept for a week, wanted .3125, or nearly one-thirteenth, of its original weight.

When bread is newly taken out of the oven, it has a peculiar and rather pleasant smell, which it loses by keeping, unless its moisture is preserved by wrapping it round with a moist cloth, as it does also the peculiar taste by which new bread is distinguished. This shows us that the bread undergoes chemical changes; but what these changes are, or what the peculiar substance is to which the odour of bread is owing, is not known.

Bread differs very completely from the flour of which it is made, for none of the ingredients of the flour can now be discovered in it. The only chemist who has attempted an analysis of bread, is Mr. Geoffroy. He found that 100 parts of bread contained the following ingredients:

24.735 water
32.030 gelatinous matter, extracted by boiling water
39.843 residuum insoluble in water

96.608
3.392 loss

100.

Fermentation, *vinous*. Under this name are comprehended every species of fermentation which terminates in the formation of an intoxicating liquid. Now these liquids, though numerous, may all be comprehended under two heads; those obtained from the juices of plants, and those obtained from the decoctions of seeds. These two heads may be distinguished by the names of the most remarkable products belonging to each, viz. wine and beer. Let us take a view of each of these.

1. *Wine*.—There is a considerable number of ripe fruits from which a sweet liquor may be expressed, having at the same time a certain degree of acidity. Of such fruits we have the apple, the cherry, the gooseberry, the currant, &c. but by far the most valuable of these fruits is the grape, which grows luxuriantly in the southern parts of Europe. From grapes fully ripe may be expressed a liquid of a sweet taste, to which the name of must has been given. This liquid is composed almost entirely of five ingredients, viz. water, sugar, jelly, gluten, and a mixed acid, partly saturated with potass. The quantity of sugar which grapes fully ripe contain is very considerable; it may be obtained in crystals, by evaporating must to the consistence of syrup, separating the tartar which precipitates during the evaporation and then setting the must aside for some months. The crystals of sugar are gradually formed. From a French pint of must, the marquis de Bullion extracted half an ounce (French) of sugar, and $\frac{1}{16}$ ounce of tartar. According to Proust, the Muscadine grape contains ubout 30 per cent. of a peculiar species of sugar.

When must is put into the temperature of about 70°, the different ingredients begin to act upon each other, and what is called vinous fermentation commences. The phenomena of this fermentation are, an intestine motion in the liquid, it becomes thick and muddy, its temperature increases, and carbonic acid gas is evolved. In a few days the fermentation ceases, the thick part subsides to the bottom or rises to the surface, the liquid becomes clear, it has lost its saccharine taste and assumed a new one, its specific gravity is diminished; and, in short, it has become the liquid well known under the name of wine.

These changes are produced altogether by the mutual action of the substances contained in must; for they take place equally, and wine is formed equally well, in close vessels as in the open air.

If the must is evaporated to the consistency of a thick syrup, or to a rob, as the elder chemists termed it, the fermentation will not commence, though the proper temperature, and every thing else necessary to produce fermentation, should be present. But if this syrup is again diluted with water, and placed in favourable circumstances, it will ferment. The presence of water therefore is absolutely necessary for the existence of vinous fermentation. But, on the other hand, if the must is too much diluted with water, it either refuses to ferment altogether, or its fermentation is very languid.

If the juice of those fruits which contain but little sugar, as currants, is put into a favourable situation, fermentation indeed takes place, but so slowly, that the product is not wine but vinegar; but if a sufficient quantity of sugar is added to these very juices, wine is readily produced. No substance whatever can be made to undergo vinous fermentation, and to produce wine, unless sugar is present. Sugar therefore is absolutely neccessary for the existence of vinous fermentation; and we are certain that it is decomposed during the process, for no sugar can be obtained from properly fermented wine. It has been sufficiently demonstrated by the experiments of Macquer, and the observations of Chaptal, that the strength of the wine is always proportional to the quantity of sugar contained in the must. From the experiments of Bullion we learn, that when must contains little sugar, the fermentation is rapid, but the product yields little alcohol. When the proportion of sugar is great, the fermentation is slow, but the product yields much alcohol.

All those juices of fruits which undergo the vinous fer-

mentation, either with or without the addition of sugar, contain an acid. The apple, for instance, contains malic acid; the lemon, citric acid; the grape, tartaric and malic acids. The marquis de Bullion has ascertained that must will not ferment if all the tartar which it contains is separated from it, but it ferments perfectly well on restoring that salt. The same chemist ascertained, that the strength of wine is considerably increased by adding tartar and sugar to the must. We may conclude from these facts, that the presence of a vegetable acid is necessary for the commencement of the vinous fermentation. It deserves attention that Bullion obtained more tartar from verjuice than from wine; and he observed that the more the proportion of sugar in grapes increased, the more that of tartar diminished.

All the juices of fruits which undergo the vinous fermentation contain an extractive matter, composed of what Deyeux has called the sweet principle. This substance has not been examined with much precision; but it seems to consist of mucilage, gluten, and extract. Now the presence of this substance is also necessary for the commencement of fermentation. For sugar, though diluted with water, and mixed with a vegetable acid, refuses to ferment, unless some mucilaginous matter is added. Bullion found that sugar, tartar, and water, did not ferment; but on adding vine-leaves the fermentation became rapid. And Bergman found that sugar dissolved in four times its weight of water, and mixed with yeast, undergoes the vinous fermentation; and the experiment has been often repeated since. In both these cases the ferment appears to be gluten.

Thus we see, that for the production of wine, a certain temperature, a certain portion of water, sugar, a vegetable acid, and gluten, are necessary. M. Lavoisier found that sugar would not ferment unless dissolved in at least four times its weight of water. This seems to indicate that the particles of sugar must be removed to a certain distance from each other before the other ingredients can decompose them.

When all these substances exist in must in proper proportions, the fermentation commences very speedily, provided the liquid is placed in a proper temperature; and its rapidity (other things remaining the same) is always proportioned to the quantity of liquid exposed at once to fermentation. The heat evolved is always proportioned to the rapidity of the process, and indeed may be looked upon as the great cause of that rapidity. According to Chaptal, the temperature during fermentation is never lower than 60°, and sometimes it is as high as 95.

During the fermentation, the quantity of sugar is constantly diminishing; and when the process is completed, the whole of the sugar is decomposed. The liquid has become more fluid, specifically lighter, and has acquired a vinous taste, owing to the formation of alcohol. Whether the other substances which constitute a part of the must have undergone any change, or whether they have merely contributed to the decomposition of the sugar, is not precisely known. The experiments of Lavoisier, to whom we are indebted for the first precise explanation of fermentation, render the second supposition most probable. From these experiments it follows that the sugar is divided into two portions; one portion separates in the form of carbonic acid, and the other, containing a great excess of hydrogen, remains under the form of alcohol. This alcohol is combined with the colouring matter, and with the acids of the wine, so intimately, that it can only be separated by distillation. The carbonic acid carries along with it a certain portion of alcohol, as was pointed out some time ago by Chaptal. The extractive matter separates, either precipitating to the bottom or swimming on the surface.

It seems more than probable, from the experiments of Bullion and Chaptal, that the tartaric acid is partly decomposed during the fermentation, and that a portion of malic acid is formed. The process, therefore, is more complicated than was suspected by Lavoisier. It is obviously analogous to combustion, as is evident from the evolution of caloric and the formation of carbonic acid, which is a product of combustion. Proust has ascertained, that during the fermentation not only carbonic acid, but azotic gas also, is disengaged. This is a demonstration, that all the constituents of must are concerned; for sugar does not contain that principle.

After the fermentation has ceased, the liquor is put into casks, where the remainder of the sugar is decomposed by a slow fermentation; after which the wine, decanted off from the extractive matter, is put up in bottles.

The properties of wine differ very much from each other, according to the nature of the grapes from which the must was extracted, and according to the manner in which the process was conducted. These differences are too well known to require a particular description. But all wines contain less or more of the following ingredients, not to mention water, which constitutes a very great proportion of every wine.

1. *An acid.*—All wines give a red colour to paper stained with turnsole, and of course contain an acid. Chaptal has ascertained that the acid found in greatest abundance in wine is the malic, but he found traces also of citric acid, and it is probable that wine is never entirely destitute of tartar. All wines which have the property of frothing when poured into a glass, contain also carbonic acid, to which they owe their briskness. This is the case with champaign. These wines are usually weak; their fermentation proceeds slowly, and they are put up in close vessels before it is over. Hence they retain the last portions of carbonic acid that have been evolved.

2. *Alcohol.*—All wine contains less or more of this principle, to which it is indebted for its strength; but in what particular state of combination it exists in wine, cannot be easily ascertained. It is undoubtedly intimately combined with the other component parts of wine; as Fabroni has shown that it cannot be separated by saturating the wine with dry carbonat of potass, though a very small portion of alcohol, added on purpose to wine, may be easily separated by means of that salt. But as alcohol separates along with the carbonic acid during the fermentation, we can scarcely doubt that it has been formed. When wine is distilled, the alcohol readily separates. The distillation is usually continued as long as the liquid which comes over is inflammable. The quantity obtained varies according to the wine, from a fourth part to a fourteenth part of the wine dis-

tilled. The spirit thus obtained is well known under the name of brandy. Bullion has observed, that when wine is distilled new, it yields more alcohol than if it is allowed to get old. What remains after this distillation is distinguished in France by the name of vinasse. It consists of tartar, &c. and when evaporated to dryness, and subjected to combustion, yields potass.

3. *Extractive matter.*—This matter exists in all wines; but its proportion diminishes according to the age of the wine, as it gradually precipitates to the bottom.

4. Every wine is distinguished by a peculiar flavour and odour, which probably depend upon the presence of a volatile oil, so small in quantity that it cannot be separated.

5. The colouring matter of wine is originally contained in the husk of the grape, and is not dissolved till the alcohol is developed. This matter is analogous to the other colouring matters of plants; a set of bodies possessed of remarkable properties, but too little examined hitherto to be capable of a clear explanation. This colouring matter precipitates when the wine is exposed to the heat of the sun. It sometimes also precipitates in old wine, and it may be easily separated by pouring lime-water into wine.

If wine be exposed to the heat of the sun during the summer, the colouring matter is detached in a pellicle, which falls to the bottom: when the vessel is opened, the discolouring is more speedy, and it is effected in two or three days during the summer. The wine thus deprived of its colour is not perceptibly weakened.

The following table, containing the different substances which Neumann extracted from various wines, is worth preserving.

A quart of	Highly rectified spirit.			Thick, oily, unctuous, resinous matter.			Gummy and tartarous matter.			Water.

To this head belong not only common wine, but all the intoxicating liquors made from vegetable juices; as cyder from apples, perry from pears, currant wine, &c. likewise the liquor made from the juice of the sugar-cane, the sugar-maple, &c.

II. *Beer.*—The method of making beer, though undoubtedly not so obvious as that of making wine, was, notwithstanding, known in the most remote ages. Whatever grain is employed, the process is nearly the same. The barley is steeped in water for about 60 hours, in order to saturate it with the liquid. (See MALTING.) It ought then to be removed as speedily as possible, otherwise the water dissolves and carries off the most valuable part of the grain. The barley is then to be laid in a heap for 24 hours; heat is evolved, oxygen gas absorbed, carbonic acid gas emitted, and germination commences with the shooting forth of the radicle. It is then spread upon a cool floor, dried slowly, and is afterwards known by the name of malt.

Malt, previously ground to a coarse powder, is to be infused in a sufficient quantity of pure water, of the temperature of 160° for an hour. The infusion is then to be drawn off, and more water may be added, at a higher temperature, till all the soluble part of the malt is extracted. This infusion is known by the name of wort. It has a sweet taste, and contains a quantity of saccharine, and doubtless also of gelatinous matter. See BREWING.

The wort is immediately conveyed to a boiler, where it is boiled with hops, or some other equivalent bitter. It is then put into large fermenting vats.

When wort is placed in the temperature of about 60°, fermentation gradually takes place in it, and the very same phenomena appear which distinguish the production of wine. The fermentation of wort then, is nothing but a particular case of the vinous fermentation. But wort does not ferment so well, nor so soon, nor does it produce nearly so great a quantity of good fermented liquor, as when yeast is added to it. The reason of which is, probably, that the fermentation does not commence till an acid is generated in the wort, and before that happens part of the saccharine contents are decomposed; whereas the yeast adds an acid, or at least something equivalent to it, at once.

Wort ferments in close vessels, as Mr. Collier ascertained by experiment, equally well as in the open air. The decomposition, therefore, is produced entirely by the substances contained in the wort, without the addition of any thing from the air. The quantity of beer produced in close vessels is much greater than when the process takes place in the open air. The reason of which is, that in the open air the beer gradually evaporates during the fermentation. Thus M. Collier found that 11 quarts, $3\frac{1}{2}$ oz. fermented in open vessels, lost in 12 days 40 oz. whereas an equal weight, fermented in close

vessels, lost only 8 oz. in the same time. Yet the quality of the beer was the same in each; for equal quantities of both, when distilled, yielded precisely the same portion of alcohol.

During the fermentation a quantity of carbonic acid gas is constantly disengaged, not in a state of purity, but containing, combined with it, a portion of the wort; and if this gas is made to pass through water, it will depose wort, which may be fermented in the usual manner.

When beer is distilled, alcohol is obtained, and the residuum is an acid liquor, the nature of which is still unknown. The theory of beer is so obviously the same with that of wine, that it requires no additional explanation.

Fermentation, *acetous*. If wine or beer is kept in a temperature between 70° and 90°, it gradually becomes thick, its temperature augments, filaments are seen moving through it in every direction, and a kind of hissing noise may be distinguished. These intestine motions gradually disappear, the filaments attach themselves to the sides and bottom of the vessel, and the liquor becomes transparent. But it has now lost its former properties, and is converted into acetous acid. This intestine decomposition has been long distinguished by the name of acetous fermentation, because its product is acetic acid. That this fermentation may take place, certain conditions must be attended to. The most important of these will appear from the following observations:

1. Neither pure alcohol, nor alcohol diluted with water, is susceptible of this change. The weaker the wine or the beer on which the experiment is made, the more readily it is converted into vinegar; the stronger they are, they resist the change with the greatest obstinacy. But it results from the experiments of Beecher, that strong wines, when they are made to undergo the acetous fermentation, yield a much better and stronger vinegar than weak wines. Hence it follows that alcohol, though of itself it refuses to undergo the change, yet when other bodies are present which readily ferment, it is decomposed during the process, and contributes to the formation of the acetic acid.

2. Wine, entirely deprived of extractive matter either by spontaneous deposition or by clarification, does not undergo the acetous fermentation, unless some mucilaginous matter is mixed with it. Chaptal exposed old wine destitute of this matter, in open bottles, to the greatest summer-heat of Montpelier for 40 days, and yet it did not become sour; but upon adding some vine-leaves to the same wine, it became acid in a few days.

3. Wine never becomes sour, provided it is completely deprived of all access to atmospheric air. The reason is, that during the acetous fermentation, oxygen is absorbed from the atmosphere in abundance; and unless that absorption can take place, no vinegar is ever formed. Hence the reason that wine or beer is more apt to become sour after the cork has been drawn, and still more apt when part has been poured out of the bottle.

4. A pretty high temperature is necessary for the commencement of the acetous fermentation. Wine or beer (unless very weak) scarcely becomes sour under the temperature of 65° or 70°. The fermentation is very apt to commence when the temperature suddenly rises. Hence wine and beer are more apt to become sour at certain seasons of the year than at others.

5. When the acetous fermentation is completed, the whole of the malic acid originally contained in the wine has disappeared as well as the alcohol. We must conclude, therefore, that they have both been converted into acetic acid. Part of the extractive matter has also undergone the same change, and seems indeed to have been the substance that first began the absorption of oxygen. Part of it is deposited in the state of flakes; part remains in solution, and disposes the vinegar to decomposition. Vinegar also contains a little tartar, and probably also citric acid. Malic acid is also found in new vinegar; a proof that this part of the wine is the last to undergo the acetous fermentation.

6. Acetic acid is formed in many other cases of the decomposition of vegetables besides the acetous fermentation. These have been pointed out with much ingenuity by Vauquelin and Fourcroy. They may be reduced under three heads: 1st. When sugar, gum, tartar, wood, &c. are distilled in a retort, or even burnt in the open fire, acetic acid separates in combination with an empyreumatic oil which distinguishes its odour. Hence it was mistaken for other acids, and distinguished by the names of pyromucous, pyrolignous, pyrotartarous acids, till its real nature was ascertained by these distinguished chemists. 2dly. When concentrated sulphuric acid is poured upon the same vegetable bodies, they are decomposed in a very different manner, being converted into water, charcoal, and acetic acid. 3dly. Acetic acid is evolved in considerable quantity during the spontaneous decomposition of urine, and some other animal substances. Thus it appears, that the component parts of this important acid are extremely apt to combine together in those proportions which constitute it.

Fermentation, *putrid*, as it has been termed by the old chemists, is that process which converts vegetable and animal matters into soil. It is, however, not fermentation, but a different process, wanting almost all the characteristics of fermentation, and therefore will be treated separately under the article Putrefaction.

FERN. See Felix.

FERRARIA, a genus of the triandria order, in the gynandria class of plants, and in the natural method ranking under the sixth order, ensatæ. The spathæ are uniflorous; the petals six in number, and wavingly curled; the stigmata cucullated or cowled; the capsule is trilocular, inferior. There are two species, natives of the Cape of Good Hope and Mexico. There is a great singularity in the root of one of these species, that it vegetates only every other year, and sometimes every third year; in the intermediate time it remains inactive, though very sound and good.

FERRET, in zoology. See Mustela.

FERRUGINOUS, any thing partaking of iron, or that contains particles of that metal. It is particularly applied to certain mineral springs, whose waters are impregnated with the particles of iron generally termed chalybeats. See Mineral Waters.

FERRY, is a liberty by prescription, or the king's grant, to have a boat for passage upon a river, for car-

riage of horses and men, for reasonable toll. Savil, 11 & 14. The owner of a ferry cannot suppress that ferry, and put up a bridge in its place, without a licence. Show. 243. 257.

FERRUM. See IRON, CHEMISTRY, &c.

FERULA, *fennel giant*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The fruit is oval, compressed plane, with three striæ on each side. There are nine species, all of them herbaceous perennials, rising from three to ten or twelve feet high, with yellow flowers. They are propagated by seeds, which should be sown in autumn, and when planted out, ought to be four or five feet distant from each other, or from any other plants; for no other will thrive under their shade. The drug assafoetida is obtained from a species of ferula, though not peculiarly; being also produced by some other plants. See Plate LX. Nat. Hist. fig. 206.

FERULA, in the ancient Eastern church, signified a place separated from the church, wherein the audientes were kept, as not being allowed to enter the church; whence the name of the place, the persons therein being under penance or discipline. This word was sometimes used to denote the prelate's crozier or staff.

FESSE, in heraldry, one of the nine honourable ordinaries, consisting of a line drawn directly across the shield, from side to side, and containing the third part of it, between the honour-point and the nombril.

FESTI DIES, in Roman antiquity, certain days in the year devoted to the honour of the gods. Numa, when he distributed the year into twelve months, divided the same into the dies festi, dies profesti, and dies intercisi. The festi were again divided into days of sacrifices, banquets, games, and feriæ.

The profesti were those days allowed to men for the administration of their affairs, whether of a public or private nature; these were divided into fasti, comitales, comperendini, stati, and præliares.

The intercisi were days common both to gods and men, some parts of which were allotted to the service of the one, and some to that of the other.

FESTINO, in logic, the third mood of the second figure of syllogism, the first proposition whereof is an universal negative, the second a particular affirmative, and the third a particular negative; as in the following example:

FES No bad man can be happy:
TI Some rich men are bad men:
NO *Ergo*, some rich men are not happy.

FEUD-BOTE, a recompence for being concerned in a feud or quarrel.

FEVER, *febris*, in medicine, a disease, or rather class of diseases, whose characteristic is a preternatural heat felt through the whole body, or at least the principal parts of it. See MEDICINE.

FIBRARIÆ, a class of fossils. See ASBESTOS.

FIBRE, in anatomy, a perfect simple body, or at least as simple as any thing in the human structure, being fine and slender like a thread, and serving to form other parts. Hence some fibres are hard, as the bony ones; and others soft, as those destined for the formation of all the other parts.

FIBRINA, is that substance which constitutes the fibrous part of the muscles of animals. If a quantity of blood, newly drawn from an animal, be allowed to remain at rest for some time, a thick red clot gradually forms in it, and subsides. Separate this clot from the rest of the blood, put it into a linen cloth, and wash it repeatedly in water till it ceases to give out any colour or taste to the liquid; the substance which remains after this process is denominated fibrina. It has been long known to physicians under the name of the fibrous part of the blood, but has not till lately been accurately described.

It may be procured also from the muscles of animals. Mr. Hatchett, to whom we are indebted for a very interesting set of experiments on this substance, cut a quantity of lean beef into small pieces, and macerated it in water for 15 days, changing the water every day, and subjecting the beef to pressure at the same time, in order to squeeze out the water. As the weather was cold, it gave no signs of putrefaction during this process. The shreds of muscle, which amounted to about three pounds, were now boiled for five hours every day for three weeks in six quarts of fresh water, which was regularly changed every day. The fibrous part was now pressed, and dried by the heat of a water-bath. After this treatment it might be considered as fibrina nearly as pure as it can be obtained.

Fibrina is of a white colour, has no taste nor smell; and is not soluble in water nor in alcohol. When newly extracted from blood, it is soft and elastic, and resembles very much the gluten of vegetables. Its colour deepens very much in drying. That which is extracted from muscle by boiling and maceration has a certain degree of transparency, and is not ductile but brittle. Its colour does not deepen nearly so much as the fibrina from blood.

It undergoes no change, though kept exposed to the action of air; neither does it alter speedily, though kept covered with water. Mr. Hatchett kept a quantity of the fibrina which he had prepared from beef moistened with water during the whole month of April; it acquired a musty but not a putrid smell, neither were the fibres reduced to a pulpy mass. Even when kept two months under water, it neither became putrid, nor was converted into the fatty matter obtained by macerating recent muscle.

When fibrina is exposed to heat, it contracts very suddenly, and moves like a bit of horn, exhaling at the same time the smell of burning feathers. In a stronger heat it melts. When exposed to destructive distillation it yields water, carbonat of ammonia, a thick heavy fetid oil, traces of acetic acid, carbonic acid, and carbureted hydrogen gas. The charcoal, as Mr. Hatchett ascertained, is more copious than that left by gelatine or albumen. It is very difficult to incinerate, owing to the presence of phosphat of soda and some phosphat of lime, which form a glassy coat on the surface. A considerable proportion of carbonat of lime also remains after the incineration of the charcoal.

Acids dissolve fibrina with considerable facility. Sulphuric acid gives it a deep-brown colour, charcoal is precipitated, and acetic acid formed. Muriatic acid dissolves it, and forms with it a green-coloured jelly. The acetic, citric, oxalic, and tartaric acids, also dissolve it by the assistance of heat; and the solutions, when concen-

trated, assume the appearance of jelly. Alkalies precipitate the fibrina from acids in flakes, soluble in hot water, and resembling gelatine in its properties.

Diluted nitric acids occasions the separation of a considerable portion of azotic gas, as was first observed by Berthollet. Mr. Hatchett steeped a quantity of fibrina in nitric acid, diluted with thrice its weight of water. for 15 days. The acid acquired a yellow tinge, and possessed all the properties of the nitric solution of albumen. The fibrina thus treated dissolved in boiling water, and when concentrated by evaporation, became a gelatinous mass, soluble in hot water, and precipitated by tan and nitromuriat of tin, and therefore possessing the properties of gelatine. Ammonia dissolves the greater part of the fibrina after it has been altered by nitric acid. The solution is of a deep orange-colour, similar to the solution of albumen treated in the same way. Boiling nitric acid dissolves fibrina, except some fatty matter which swims on the surface. The solution resembles that of albumen, except that ammonia throws down a white precipitate, consisting chiefly of oxalat of lime. During the solution, prussic acid comes over, and carbonic acid gas mixed with nitrous gas; a considerable portion of oxalic acid is formed, besides the fatty matter which swims. It is probable that this last substance does not differ much from the substance formed by causing nitric acid to act upon the muscles of animals, which the French chemists have distinguished by the name of adipocire.

The alkalies, while diluted, have but little effect upon fibrina; but when concentrated potass or soda is boiled upon it, a complete solution is obtained of a deep-brown colour, possessing the properties of soap. During the solution, ammonia is disengaged. When the solution is saturated with muriatic acid, a precipitate is obtained similar to that from animal soap, except that it sooner becomes hard and soapy when exposed to the air.

The earths, as far as is known, have little or no action on fibrina. Neither has the action of the metallic oxides and salts been examined.

Fibrina is insoluble in alcohol, ether, and oils. The effect of other reagents on it has not been examined.

From the properties above detailed, fibrina appears to be composed of the same constituents as albumen and gelatine; but it probably contains more carbon and azote, and possibly less oxygen. The close resemblance which it bears to albumen is very obvious from the experiments of Mr. Hatchett just detailed. Nitric acid converts both into gelatine, and alkalies convert both into a species of oil. Now as all the soft parts of animals consist of combinations of these three genera, it follows, as Mr. Hatchett has observed, that all the soft parts of animals may be either converted into gelatine or animal soap, both substances of the highest importance.

Fibrina exists only in the blood and the muscles of animals; but it is a genus which includes as many species as there are varieties in the muscles of animals, and the great variety of these substances is well known. The muscles of fish, of fowl, and of quadrupeds, bear scarcely any resemblance to each other.

A substance exactly resembling the fibrina, as it exists in the blood, has been detected by Vauquelin in the juice of the papaw-tree; the same juice which contained

albumen in such plenty. Fibrina then must be ranked among vegetable substances.

When the juice of the papaw is treated with water, the greatest part dissolves; but there remains a substance insoluble, which has a greasy appearance. It softens in the air, and becomes viscid, brown, and semi-transparent. When thrown on burning coals it melted, let drops of grease exude, emitted the noise of meat roasting, and produced a smoke which had the odour of fat volatilized. It left behind it no residue. This substance was the fibrina. The resemblance between the juice of the papaw and animal matter is so close, that we should almost be tempted to suspect some imposition, was not the evidence that it is really the juice of a tree quite unexceptionable.

The properties of fibrina are the following:

1. It is tasteless, fibrous, elastic, and resembles gluten.
2. It is insoluble in water and in alcohol.
3. It is not dissolved by alkalies.
4. But acids dissolve it without difficulty.
5. With nitric acid it gives out much azotic gas.
6. When distilled it yields much carbonat of ammonia and oil.
7. It soon putrifies when kept moist, becomes green, but does not acquire any resemblance to cheese. See Gluten.

FIBROLETE, a mineral, first observed by Bournon, in the matrix of the imperfect corundum. Colour white or dirty grey; specific gravity 3 214; texture fibrous; cross fracture compact; internal lustre glossy; infusible by the blowpipe. Usually in shapeless fragments. It is composed of

58.25	alumina
38.00	silica
3.75	a trace of iron, and loss.
100.00	

FIBULA, in anatomy, the outer and smaller bone of the leg.

FICTION of law, is allowed of in several cases; but it must be framed according to the rules of law; and there ought to be equity and possibility in every legal fiction.

Fictions were invented to avoid inconvenience; and it is a maxim invariably observed, that no fiction shall extend to work an injury, its proper operation being to prevent a mischief, or remedy an inconvenience, that might result from the general rule of law. 3 Black. 434.

All fictions of law are to certain respects and purposes, and extend only to certain persons; as the law supposes the vouchee to be tenant of the land, where in rei veritate he is not; but this is as to the demandant himself, and to enable him to do things as to the demandant, and which the demandant may do to him; and therefore a fine levied by vouchee to the demandant, or fine or release from the defendant to the vouchee, is good; but fine levied by the vouchee to a stranger, or lease made to him by a stranger, is void. 3 Rep. 29. See Fine, and Recovery.

FICUS, a genus of the triœcia order, in the polygamia class of plants, and in the natural method ranking

under the 53d order, scabridæ. The receptacle is common, turbinated, carnous, and connivent; inclosing the florets either in the same or in a distinct one. The male calyx is tripartite: no corolla; three stamina: the female calyx is quinquepartite; no corolla; one pistil; and one seed. There are 56 species, of which the following are the most remarkable.

1. Ficus indica, or banian-tree, is a native of several parts of the East Indies. It has a woody stem, branching to a great height and vast extent, with heart-shaped entire leaves ending in acute points. This tree is beautifully described by Milton in Paradise Lost, book ix. l. 1100.

Indeed the banian-tree, or Indian fig, is perhaps the most beautiful of nature's productions in that genial climate, where she sports with so much profusion and variety. Some of these trees are of amazing size and great extent, as they are continually increasing, and, contrary to most other things in animal and vegetable life, seem to be exempted from decay. Every branch from the main body throws out its own roots; at first, in small tender fibres, several yards from the ground: these continually grow thicker until they reach the surface; and there striking in, they increase to large trunks, and become parent trees, shooting out new branches from the top: these in time suspend their roots, which, swelling into trunks, produce other branches; thus continuing in a state of progression as long as the earth, the first parent of them all, contributes her sustenance. The Hindoos are peculiarly fond of the banian-tree; they look upon it as an emblem of the Deity, from its long duration, its out-stretching arms, and overshadowing beneficence; they almost pay it divine honours, and

"Find a fane in every sacred grove."

Near these trees the most esteemed pagodas are generally erected; under their shade the Brahmins spend their lives in religious solitude; and the natives of all casts and tribes are fond of recreating in the cool recesses, beautiful walks, and lovely vistas of this umbrageous canopy, impervious to the hottest beams of a tropical sun.

A remarkable large tree of this kind grows on an island in the river Nerbedda, ten miles from the city of Baroche, in the province of Guzerat, a flourishing settlement lately in the possession of the East India company, but ceded by the government of Bengal, at the treaty of peace concluded with the Mahrattas in 1783, to Mahdajee Scindia, a Mahratta chief. It is distinguished by the name of Cubbeer Burr, which was given it in honour of a famous saint. It was once much larger than at present; but high floods have carried away the banks of the island where it grows, and with them such parts of the tree as had thus far extended their roots; yet what remains is about 2000 feet in circumference, measured round the principal stems; the overhanging branches, not yet struck down, cover a larger space. The chief trunks of this single tree (which in size greatly exceed our English elms and oaks) amount to 350; the smaller stems, forming into stronger supporters, are more than 3000; and every one of these is casting out new branches, and hanging roots, in time to form trunks, and become the parents of a future progeny. Cubbeer Burr is famed throughout Hindostan for its great extent and surpassing beauty: the Indian armies generally encamp around it, and at stated seasons, solemn jatarras, or Hindoo festivals, are held there, to which thousands of votaries repair from various parts of the Mogul empire. It is said that 7000 persons find ample room to repose under its shade. The English gentlemen, on their hunting and shooting parties, used to form extensive encampments, and spend weeks together under this delightful pavilion; which is generally filled with green wood-pigeons, doves, peacocks, and a variety of feathered songsters; crowded with families of monkeys performing their antic tricks, and shaded by bats of a large size, many of them measuring upwards of six feet from the extremity of one wing to the other. This tree not only affords shelter, but sustenance, to all its inhabitants, being covered amidst its bright foliage with small figs of a rich scarlet, on which they all regale with as much delight as the lords of creation on their more various and costly fare.

2. The sycamorus, or sycamore of scripture. According to Mr. Hasselquist, this is a huge tree, the stem being often 50 feet round. The fruit is pierced in a remarkable manner by an insect. There is an opening made in the calyx near the time the fruit ripens, which is occasioned in two different ways: 1. When the squamæ, which cover the calyx, wither and are bent back, which, however, is more common to the carica than the sycamore. 2. A little below the scales, on the side of the flower-cup, there appears a spot before the fruit is ripe; the fruit in this place is affected with a gangrene which extends on every side, and frequently occupies a finger's breadth. It withers; the place affected becomes black; the fleshy substance in the middle of the calyx, for the breadth of a quill, is corroded; and the male blossoms, which are nearest to the bare side, appear naked, opening a way for the insect, which makes several furrows in the inside of the fruit, but never touches the stigmata, though it frequently eats the germen. The wounded or gangrenous part is at first covered or shut up by the blossoms; but the hole is by degrees opened and enlarged of various sizes in the different fruits; the margin and sides being always gangrenous, black, hard, and turned inwardly. The same gangrenous appearance is also found near the squamæ, after the insect has made a hole in that place. The tree is very common in the plains and fields of Lower Egypt. It buds in the end of March, and the fruit ripens in the beginning of June. It is wounded or cut by the inhabitants at the time it buds; for without this precaution they say it would not bear fruit.

3. The carica, or common fig, with an upright stem branching 15 or 20 feet high, with large palmated or hand-shaped leaves. Of this there are a number of varieties; as the common fig, a large, oblong, dark purplish-blue fruit, which ripens in August either on standards or walls, and the tree carries a great quantity of fruit. The brown or chesnut fig; a large, globular, chesnut-coloured fruit, having a purplish delicious pulp, ripening in July and August. The black Ischia fig; a middle-sized, shortish, flat-crowned, blackish fruit, having a bright pulp, ripening in the middle of August. The green Ischia fig; a large, oblong, globular-headed, greenish fruit, slightly stained by the pulp to a reddish-brown co-

lour, ripens in the end of August. The brown Ischia fig; a small, pyramidal, brownish-yellow fruit, having a purplish very rich pulp, ripening in August and September. The Malta fig; a small flat-topped brown fruit, ripening in the middle of August or beginning of September. The round brown Naples fig; a globular, middle-sized, light-brown fruit, and brownish pulp, ripe by the end of August. The long brown Naples fig; a long dark-brown fruit, having a reddish pulp, ripe in September. The great blue fig; a large blue fruit, having a fine red pulp. The black Genoa fig; a large, pear-shaped, black-coloured fruit, with a bright red pulp, ripe in August.

Culture.—The last species is that most frequently cultivated in this country, and the only one which does not require to be kept in a stove. It may be propagated either by suckers arising from the roots, by layers, or by cuttings. The suckers are to be taken off as low down as possible; trim off any ragged part at bottom, leaving the tops entire, especially if for standards, and plant them in nursery lines at two or three feet distance from each other, or they may at once be planted where they are to remain, observing, that if they are designed for walls or espaliers, they may be headed to six or eight inches in March, the more effectually to force out lateral shoots near the bottom; but if intended for standards, they must not be topped, but trained with a stem, not less than 15 or 18 inches for dwarf-standards, a yard for half-standards, and four, five, or six feet for full standards. They must then be suffered to branch out to form a head; observing that whether against walls, espaliers, or standards, the branches or shoots must never be shortened, unless to procure a necessary supply of wood: for the fruit is always produced on the upper parts of the young shoots; and if these are cut off, no fruit can be expected. The best season for propagating these trees by layers is in autumn; but it may be also done any time from October to March or April. Choose the young pliable lower shoots from the fruitful branches; lay them in the usual way, covering the body of the layers three or four inches deep in the ground, keeping the top entire, and as upright as possible, and they will be rooted and fit to separate from the parent in autumn; when they may be planted either in the nursery, or where they are to remain, managing them as above directed. The time for propagating by cuttings is either in autumn at the fall of the leaf, or any time in March. Choose well-ripened shoots of the preceding summer, short, and of robust growth, from about 12 to 15 inches long, having an inch or two of the two-years wood at their base, the tops left entire, and plant them six or eight inches deep, in a bed or border of good earth, in rows two feet asunder; and when planted in autumn, it will be eligible to protect their tops in time of hard frost, the first winter, with any kind of long loose litter.

That part of the history of the fig-tree, which for many ages was so enigmatical, namely, the caprification, as it is called, is particularly worthy of attention, not only as a singular phænomenon in itself, but as it has furnished one of the most convincing proofs of the reality of the sexes in plants. In brief it is this: the flowers of the fig-tree are situated within a pulpy receptacle, which we call the fig or fruit; of these receptacles, in the wild fig-tree, some have male flowers only, and others have male and female, both distinct, though placed in the same receptacle. In the cultivated fig, these are found to contain only female flowers, which are fecundated by means of a kind of gnat bred in the fruit of the wild fig-trees, which pierces that of the cultivated, in order to deposit its eggs within; at the same time diffusing within the receptacle the farina of the male flowers. Without this operation the fruit may ripen, but no effective seeds are produced. Hence the garden fig can only be propagated by layers and cuttings in those countries where the wild fig is not known. The process of thus ripening the fruit, in the Oriental countries, is not left to nature, but is managed with great art, and different degrees of dexterity, so as to reward the skilful husbandman with a much larger increase of fruit than would otherwise be produced. A tree of the same size which in Provence, where caprification is not practised, may produce about 25 pounds of fruit, will by that art, in the Grecian islands, bring ten times that quantity.

Figs are a considerable article in the materia medica, chiefly employed in emollient cataplasms and pectoral decoctions. The best are those which come from Turkey. Many are also brought from the south of France, where they prepare them in the following manner. The fruit is first dipped in scalding-hot ley made of the ashes of the fig-tree, and then dried in the sun. Hence these figs stick to the hands, and scour them like lixivial salts; and for the same reason they purge gently, without griping. They are moderately nutrimental, grateful to the stomach, and easier to digest than any other of the sweet fruits. They have been said to produce lice when eaten as a common food; but this seems to be entirely without foundation. The reason of this supposition seems to be, that in the countries where they grow naturally, they make the principal food of the poor people, who are generally troubled with these vermin. The wood of the sycamore is not subject to rot, and has therefore been used for making coffins in which embalmed bodies were put. Mr. Hasselquist affirms, that he saw in Egypt coffins made of this kind of wood, which had been preserved sound for 2000 years.

FIDD, in the sea language, an iron or wooden pin, to splice and fasten ropes together. It is made taperwise, and sharp at one end. The pin in the heel of the top-mast, which bears upon the chesse-trees, is likewise called a fidd.

FIELD, in heraldry, is the whole surface of the shield, or the continent, so called because it contains those achievements anciently acquired on the field of battle. It is the ground on which the colours, bearings, metal, furs, charges, &c. are represented. Among the modern heralds, field is less frequently used in blazoning than shield or escutcheon.

Field-book, in surveying, that in which the angles, stations, distances, &c. are set down. See Surveying.

Field-colours, in war, are small flags of about a foot and a half square, which are carried along with the quarter-masters general, for marking out the ground for the squadrons and battalions.

Field-fare. See Turdus.

Field-pieces, small cannons, from three to twelve pounders, carried along with an army in the field.

Field-staff, a weapon carried by the gunners, about the length of a halbert, with a spear at the end, having on each side ears screwed on, like the cock of a match-lock, where the gunners screw in lighted matches, when they are upon command; and then the field-staffs are said to be armed.

Field-works, in fortification, are those thrown up by an army in besieging a fortress, or by the besieged to defend the place. Such are the fortifications of camps, highways, &c.

FIERI FACIAS, a writ judicial, that lies at all times within the year and day for him who has recovered in an action of debt or damages, to the sheriff, to command him to levy the debt or damages of his goods against whom the recovery was had. Upon a fieri facias, the sheriff cannot deliver the defendant's goods to the plaintiff in satisfaction of his debt; nor ought he to deliver them to the defendant against whom execution is; but the goods are to be sold, and in strictness, the money is to be brought into court. Cro. Eliz. 504.

If the defendant dies after the execution awarded, and before it is served, yet it may be served upon his goods in the hands of his executor or administrator; for if the execution is awarded, the goods are bound, and the sheriff need not take notice of his death. 1 Mod. 188. And upon a fieri facias, the sheriff may take any thing but wearing clothes. Cumb. 356.

FIFE, or *Fiffario*, a shrill wind-instrument of the martial kind, consisting of a short narrow tube, with holes disposed along the side, for the regulation of its tones. It is not blown at the end, but at the side, like a German flute.

FIFTEENTH, an ancient tribute or tax laid upon cities, boroughs, &c. throughout all England, and so termed because it amounted to a fifteenth part of what each city or town had been valued at; or it was a fifteenth of every man's personal estate according to a reasonable valuation. In Doomsday-book, there are certain rates mentioned for levying this tribute yearly. The present property-tax seems a revival of the ancient system.

Fifteenth, in music, the appellation given to a certain stop in the organ. See Stop.

Fifteenth, an interval consisting of two octaves.

FIFTH, in music, a distance comprising four diatonic intervals, *i. e.* three tones and a half. The fifth is the second of the consonances in the order of their generation.

Fifth, *sharp*. The sharp fifth is an interval consisting of eight semitones.

FIG. See Ficus.

FIGURATE *numbers*, such as do or may represent some geometrical figure. in relation to which they are always considered; as triangular, pentagonal, pyramidal, &c. numbers.

Figurate numbers are distinguished into orders, according to their place in the scale of their generation, being all produced one from another, viz. by adding continually the terms of any one, the successive sums are the terms of the next order, beginning from the first order, which is that of equal units 1, 1, 1, 1, &c.; then the 2d order consists of the successive sums of those of the first order, forming the arithmetical progression 1, 2, 3, 4, &c.; those of the 3d order the successive sums of those of the 2d, and are the triangular numbers 1, 3, 6, 10, 15, &c.; those of the 4th order are the successive sums of those of the 3d, and are the pyramidal numbers 1, 4, 10, 20, 35, &c.; and so on, as below.

Order.	Name.	Number.				
1.	Equals,	1,	1,	1,	1,	1, &c.
2.	Arithmeticals,	1,	2,	3,	4,	5, &c.
3.	Triangulars,	1,	3,	6,	10,	15, &c.
4.	Pyramidals,	1,	4,	10,	20,	35, &c.
5.	2d Pyramidals,	1,	5,	15,	35,	70, &c.
6.	3d Pyramidals,	1,	6,	21,	56,	126, &c.
7.	4th Pyramidals,	1,	7,	28,	84,	210, &c.

The above are all considered as different sorts of triangular numbers, being formed from an arithmetical progression, whose common difference is 1. But if that common difference is 2, the successive sums will be the series of the square numbers; if it be 3, the series will be pentagonal numbers, or pentagons; if it be 4, the series will be hexagonal numbers, or hexagons, and so on. Thus:

Arithmecal.	1st Sums or polygons.	2d Sums, or 2d Polygons
1, 2, 3, 4,	Tri. 1, 3, 6, 10	1, 4, 10, 20
1, 3, 5, 7,	Sqrs. 1, 4, 9, 16	1, 5, 14, 30
1, 4, 7, 10,	Pent. 1, 5, 12, 22	1, 6, 18, 40
1, 5, 9, 13,	Hex. 1, 6, 15, 28	1, 7, 22, 50
&c.		

And the reason of the names triangles, squares, pentagons, hexagons, &c. is, that those numbers may be placed in the form of these regular figures or polygons.

FIGURE, in conic sections, according to Apollonius, is the rectangle made under the latus rectum and transversum in the hyperbola and ellipsis.

Figure of the diameter; the rectangle under any diameter, and its proper parameter, is, in the ellipsis and hyperbola, called the figure of that diameter.

Figure, in fortification, the plan of any fortified place, or the interior polygon, which, when the sides and angles are equal, is called a regular, and when unequal, an irregular figure.

Figure, in geometry: the superficies included between one or more lines, is denominated either rectilinear, curvilinear, or mixt, according as the extremities are bounded by right lines, curve lines, or both.

Figure, in grammar, a deviation from the natural rules of etymology, syntax, and prosody, either for brevity, elegance or harmony.

Figure, in logic, denotes a certain order and disposition of the middle term in any syllogism.

Figures are fourfold: 1. When the middle term is the subject of the major proposition, and the predicate of the minor, we have what is called the first figure. 2. When the middle term is the predicate of both the premises, the syllogism is said to be in the second figure. 3. If the middle term is the subject of the two premises, the syllogism is in the third figure; and lastly, by making it the predicate of the major, and subject of the minor, we obtain syllogisms in the fourth figure. Each of these figures has a determinate number of moods, including all the possible ways in which propositions differing in quantity or quality can be combined, according to any disposition of the middle term, in order to arrive at a just conclusion.

Figure, in painting and designing, denotes the lines and colours which form the representation of any animal,

but more particularly of a human personage. Thus a painting it said to be full of figures when there are abundance of representations of men; and a landscape is said to be without figures when there is nothing but trees, plants, mountains, &c. See PAINTING.

FIGURE, in rhetoric, is a manner of speaking different from the ordinary and plain mode, and more emphatical, expressing a passion, or containing a beauty. See RHETORIC.

FIGURED, in music, a term applied to that descendant, which, instead of moving note by note with the bass, consists of a free and florid melody. A bass, accompanied with numerical characters, denoting the harmony formed by the upper or superior parts of the composition, and directing the chords to be played by the organ, harpsichord, or piano-forte, is called a figured bass.

FIGURES: figures are not allowed to express numbers in indictments, but numbers must be expressed in words. Cro. Car. 109.

Roman figures are good in pleading, but otherwise of English figures. 2 Lev. 102.

FILACER, FILIZER, or FILAUR, an officer of the court of common-pleas, so called because he files those writs whereon he makes out process. There are fourteen of them in their several divisions and counties, and they make out all writs and process upon original writs, issuing out of chancery, as well in real, as in personal and mixed actions; and in actions merely personal, where the defendants are returned summoned, they make out pones and attachments, which being returned and executed, if the defendant appears not, they make forth a distringas, and so ad infinitum, or until he does appear; if he is returned nihil, then process of capias infinite, &c. They enter all appearances and special bails, upon any process made by them. They make the first scire facias upon special bail, writs of habeas corpus, distringas, nuper vicecomitem vel ballivum, and duces tecum, and all supersedeas upon special bail or otherwise; writs of habeas corpus cum causa, upon the sheriff's return, that the defendant is retained with other actions; writs of adjournment of a term, in case of pestilence, war, or public disturbance.

FILAGO, a genus of the polygamia necessaria order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; there is no pappus; the calyx is imbricated; the female florets placed among the scales of the calyx. There are seven species, commonly known by the name of cudweed, natives of most parts of Europe, herbaceous, most of them annual.

FILAMENT. See BOTANY.

FILAMENTS, *vegetable*, form a substance of great use in the arts and manufactures; furnishing thread, cloth, cordage, &c. For these purposes the filamentous parts of the cannabis and linum, or hemp and flax, are employed among us. But different vegetables have been employed in different countries for the same uses. Putrefaction destroys the pulpy or fleshy matter, and leaves the tough filaments entire; by curiously macerating the leaf of a plant in water, we obtain the fine flexible fibres which constituted the basis of the ribs and minute veins, and which now form a skeleton of the leaf.

The sieur de Flacourt, in his History of Madagascar, relates, that different kinds of cloth are prepared in that island from the filaments of the bark of certain trees boiled in strong ley; that some of these cloths are very fine, and approach to the softness of silk, but in durability come short of cotton; that others are coarser and stronger, and last thrice as long as cotton; and that of these the sails and cordage of his vessel were made.

The same author informs us, that the stalks of nettles are used for the like purposes in France. And sir Hans Sloane relates, in one of his letters to Mr. Ray, that he has been informed by several, that muslin and calico, and most of the Indian linens, are occasionally made from nettles.

In some of the Swedish provinces, a strong kind of cloth is said to be prepared from hop-stalks; and in the Transactions of the Swedish academy for the year 1750, there is an account of an experiment made in consequence of that report. Of the stalks, gathered in autumn, about as many were taken, as equalled in bulk a quantity of flax that would have produced a pound after preparation. The stalks were put into water, and kept covered with it during the winter. In March they were taken out, dried in a stove, and dressed as flax. The prepared filaments weighed nearly a pound, and proved fine, soft, and white: they were spun and woven into six ells of fine strong cloth. The author, Mr. Shisler, observes, that hop-stalks take much longer time to rot than flax; and that if not fully rotted, the woody part will not separate, and the cloth will neither prove white nor fine.

Hemp, flax, and all other vegetable filaments, and thread or cloth prepared from them, differ remarkably from wool, hair, silk, and other animal productions, not only in the principles into which they are resoluble by fire, but likewise in some of their more interesting properties, particularly in their disposition to imbibe colouring matters; many liquors, which give a beautiful and durable dye to those of the animal, giving no stain at all to those of the vegetable kingdom.

Fishing-nets are usually boiled with oak-bark, or other such astringents, which render them more lasting. Those made of flax receive from this decoction a brownish colour, which, by the repeated alternations of water and air, is in a little time discharged, whilst the fine glossy brown communicated by the same means to silken nets, permanently resists both the air and water, and lasts as long as the animal filaments themselves. In like manner the stain of ink, or the black dye from solutions of iron, mixed with vegetable astringents, proves durable in silk and woollen; but from linen the astringent matter is extracted by washing, and only the yellow iron-mould remains.

Many other instances of this kind are known too well to the callico-printer, whose grand desideratum is to find means of making the fibres of cotton receive the same colours that wool does. See CALLICO-PRINTING.

FILARIA, a genus of insects of the order intestina; body round, filiform, equal, and quite smooth; mouth dilated, with a roundish concave lip. There are several species, some infesting the mammalia, other infesting birds, others infesting insects in their perfect state, and some infesting the larvæ of insects. The medinensis is the most remarkable species; it inhabits the Indies, and

is frequent in the morning dew, whence it enters the naked feet of the slaves, and creates the most troublesome itchings, accompanied with inflammation and fever. It must be cautiously drawn out by means of a piece of silk tied round its head, for if the animal should break, the remaining part grows with redoubled vigour, and is often fatal. It is frequently 12 feet long, and not larger than a horsehair.

FILBERT, or Filberd. See Corylus.

FILE, among mechanics, a tool used in metal, &c. in order to smooth, polish, or cut.

This instrument is of iron, or forged steel, cut in little furrows, with chisels, and a mallet, in a certain direction, and of a certain depth, according to the grain or touch required. After cutting the file, it must be tempered with a composition of chimney-soot, very hard and dry, diluted, and wrought up with urine, vinegar, and salt; the whole being reduced to the consistence of mustard. Tempering the files consists in rubbing them over with this composition, and covering them in loam; after which they are put into a charcoal fire, and taken out by the time they have acquired a cherry-colour, which is known by a small rod of the same steel put in along with them. Being taken out of the fire, they are thrown into cold spring-water, and when cold, they are cleaned with charcoal and a rag, and being clean and dry, are kept from rust by laying them up in wheat bran. Iron files require more heating than steel ones. Files are of different forms, sizes, cuts, and degrees of fineness, according to the different uses and occasions for which they are made. Those in common use are the square, flat, triangular, half-round, round, thin file, &c. each of which may be of different sizes, as well as different cuts.

The rough or coarse-toothed files are to take off the unevenness of the work which the hammer made in the forging; and the fine-toothed files are to take out of the work the deep cuts or file strokes of the rough files; the files succeed one another in this order, first the rubber, then the bastard-toothed file, next the fine-toothed file, and lastly the smooth file. Thus the files of different cuts succeed one another, till the work is as smooth as it can be filed; after which it may be made still smoother, by emery, tripoli, &c. In using all sorts of files, the rule is to lean heavy on the file in thrusting it forward, because the teeth of the files are made to cut forward; but in drawing the file back again for a second stroke, it is to be lightly lifted just above the work, as it does not cut in coming back.

There are several machines invented for cutting files, by which a blind man can cut a file with more exactness than can be done in the usual method with the keenest sight. These machines may be worked by water as readily as by hand, and are adapted to cut coarse or fine, large or small, files, or any number at a time. Mr. Nicholson, a few years since, obtained a patent for machinery for the manufacture of files; which consists, 1. Of a carriage in which the file is fixed and moved along, for the purpose of receiving the successive strokes of a cutter or chisel. 2. The anvil by which the file is supported beneath the part which receives the stroke. 3. The regulating gear by which the distance between stroke and stroke is determined and governed: and 4. The apparatus for giving the stroke or cut. The four several parts aforesaid are supported by a frame of solid workmanship, either of wood or metal, or both, according to the nature of the work to be performed.

The action of this machinery is thus described: 1. The file, being prepared as usual for cutting, must be fixed in the clip of the carriage, and the sliding block brought up and fixed, to steady the other extremity. 2. The nut of the screw being then opened, the carriage is slided to its place, so that the chisel may be situated over that part of the file which is to receive the first stroke. 3. The nut is then closed, and the small roller of the pressing lever is made to bear upon the face of the file. 4. The first mover being then put into action, raises and lets fall the apparatus for giving the stroke by which the file receives a cut. 5. Immediately afterwards, or during the same action, as the case may be, the regulating gear moves the carriage, and consequently the file, through a certain space. 6. This cut is then again given, and in this manner the file becomes cut throughout. The file is then taken out and cut on the other side; the bur is taken off, or not, as the artist judges fit, and the cross strokes are given over the surface as before. This machinery, by means of certain slight alterations, is adapted to the manufacture of all descriptions of files whether floats, rasps, or those of any figure and denomination.

File, in the art of war, a row of soldiers standing one behind another, which is the depth of the battalion, or squadron. The files of a battalion of foot are generally three deep, as are sometimes those of a squadron of horse. The files must be straight, and parallel one to another.

File, in law, is a record of the court; and the filing of a process of court, makes a record of it. Lill. 212.

FILIX, an order of the cryptogamia class of plants, comprehending the fern, horse-tail, adder's-tongue, maiden-hair, spleen-wort, polypody, &c.

FILUM, *in music* (Lat.), the name formerly given to the line drawn from the head of a note upwards, or downwards, and which is now called the tail.

FILLET, in heraldry, a kind of bordure, containing only a third or fourth part of the breadth of the common bordure. It is supposed to be withdrawn inwards, and is of a different colour from the field. It runs quite round, near the edge, as a lace over a cloak. It is also used for an ordinary drawn like a bar, from the sinister point of the chief, across the shield, in manner of a scarf; though it sometimes is also seen in the situation of a bend, fesse, cross, &c.

FILTER, or Filtre, in chemistry, a strainer commonly made of bibulous or filtring paper, in the form of a funnel, through which any fluid is passed, in order to separate the gross particles from it, and render it limpid.

FILTERING paper, is paper without size. To use it as such, the paper is shaped into the form of a cone, and placed in a funnel, in order to support it; otherwise it would break.

Filtering stones, basons, &c. are either natural or artificial for the purpose of purifying water. Natural filtres are found in rocks, mountains, beds of sand, gravel, &c. Artificial filtering-basons consist of equal parts of pipe-clay, and coarse sand. They should be three-quarters of an inch thick.

FILTRATION, is a finer species of sifting. It is sifting through the pores of paper, or flannel, or fine linen, or sand, or pounded glass, or porous stones, and the like; but it is used only for separating fluids from solids or particles, that may happen to be suspended in them, and not chemically combined with the fluids. Thus salt water cannot be deprived of its salt by filtration, but muddy water may be cleansed by it. No solid, even in the form of powder, will pass through filtering substances. If water or any other fluid containing sand, insects, &c. is placed in a bag or hollow vessel, made of any of those substances, the sand, &c. will remain upon the filtre, and the liquor will pass clear through it, and may be received in a vessel placed under it.

Mr. Peacock obtained, about twelve years since, a patent for a new species of filtration, by means of gravel of different sizes suitable to the several strata. The various sizes of the particles of gravel, as placed in layers, should be nearly in the quadruple ratio of their surfaces; that is, upon the first layer, a second is to be placed, the diameter of whose particles are not to be less than one-half of the first, and so on in this proportion. This arrangement of filtring particles will gradually fine the water by the grosser particles being quite intercepted in their partly ascending with the water. An advantage in these filtres is, that they may be readily cleansed by drawing out the body of the fluid, by which it will descend in the filtre, and carry with it all the foul and extraneous substances.

FIMBRIÆ, denotes appendages disposed by way of fringe round the border of any thing.

FIN, in natural history, a well-known part of fishes, consisting of a membrane supported by rays, or little bony or cartilaginous ossicles. The number, situation, and figure of fins, are different in different fishes. As to number, they are found from one to ten, or more; with respect to situation, they stand either on the back only, the belly only, or on both; and as to figure, they are either of a triangular, roundish, or oblong square form. Add to this, that in some they are very small; whereas, in others, they almost equal the whole body in length.

FINAL, *in music*, an old appellation given to the last sound of a verse in a chant; which, if complete, is on the key note; if incomplete, on some other note of the key.

FINAL Letters, among Hebrew grammarians, five letters so called, because they have a different figure at the end of words from what they have in any other situation.

FINALE (Ital.) a word signifying the last composition performed in any act of an opera, or part of a concert.

FINANCE, the œconomy of the public revenue and expenditure of nations. In former times, when the whole revenue drawn from the people by a few moderate and long-established taxes, was considered as the personal property of the sovereign, the purposes to which it was applied depended entirely on his discretion or that of his minister, as few princes were inclined in time of peace to reserve any part of their income as a provision for the additional expenses of war; the extraordinary charges incurred in times of hostility were defrayed by extraordinary contributions from the people, which ceased with the occasion of them. Few sovereigns possessed sufficient credit either with their own subjects or foreigners to contract debts, so that at the conclusion of a war there was no occasion for a greater expenditure than before its commencement, and the revenue drawn from the people reverted to its former state. It is the system of defraying extraordinary expenses by borrowing the money, for which an annual interest must be paid; and of suffering the debts thus incurred to accumulate, by which the sum to be annually paid is continually increasing, and the expenses of every war are rendered far greater than those which preceded it; that has swelled the revenue and expenditure of most of the nations of Europe to an enormous magnitude, and caused their systems of finance to become complicated and oppressive. In Great Britain, where the system of running in debt, or, as it is commonly termed, the funding system, has been carried to a greater height than in any other country, its natural attendants, enormous taxation and expenditure, have made equal progress; and it is probably owing chiefly to the publicity which is given to all matters of finance, so that every person with little trouble may know how all the money raised for the public service is expended, that the people have been induced to submit to taxes which both from their nature and amount would have appeared incredible to their forefathers.

The English system of finance rests on the produce of the various taxes which have been imposed at different periods, the aggregate amount of which, after deducting the expenses of collection, together with a few small articles which cannot properly be called taxes, forms the whole of the public income. This income is annually appropriated to the several branches of the national expenditure, and when in consequence of any extraordinary expenses it is known that the income of the current year will be insufficient to meet all the demands upon it, it is usual to borrow the sum necessary to make up the deficiency, either from individuals or public bodies, and to allow a fixed rate of interest on the money thus obtained, till the principal shall be repaid, or till the period originally agreed upon shall have expired. See Revenue, Loans, and National Debt.

The chancellor of the exchequer is, in Great Britain, the officer to whom the arrangement of the financial concerns of the country is chiefly intrusted. He causes accounts to be annually laid before parliament of the produce of the taxes, with estimates of the several branches of public expenditure for the ensuing year; and if the amount of the estimated expenditure exceeds the probable produce of the revenue, he adjusts the extent and conditions of the loan with such persons as are willing to advance the same, and proposes to parliament the new taxes which become necessary for paying the interest on the money thus borrowed. On the foundation of the accounts and estimates submitted to parliament, particular sums are voted for the several branches of the expenditure; and when the ways and means of raising the whole sum wanted have been determined, an act is passed appropriating the specific sums to the various articles forming the supplies which have been granted. In order to provide against any unforeseen expenses, it is

usual to grant also a certain sum appropriated to any particular purpose, to be applied to any branch of the expenditure in which there may be occasion for it; this is called a vote of credit, and has increased in amount with the progress of the supplies; in the American war it was 1,000,000*l.* per annum, of late it has generally been 2,500,000*l.* Soon after the commencement of each session, an account is laid before the house of commons, showing how the moneys given for the service of the preceding year have been disposed of, and what part thereof remains unpaid. If the ways and means have fallen short of the sum they were expected to produce, the deficiency is made good as an article among the next year's supplies.

All the financial accounts of Great Britain are made up annually, and do not vary materially except in the amount of the several articles. A general view of the ordinary revenues and extraordinary resources constituting the public income for the year ending the 5th January, 1805, and of the different branches of the public expenditure for the same period, will furnish a distinct and comprehensive view of the subject, for the detail of which see CUSTOMS, EXCISE, STAMP-DUTIES, LAND-TAX, &c.

FINDING: any person finding any thing, has a special property therein, but he is answerable to the person in whom is the general property, but has a right against every person but the loser. The finder is not answerable for a mere nonfeasance or neglect: yet if he makes gain of, or abuses, or spoils the things he finds, he shall be answerable. If bank-bills, tickets, &c. stolen or lost, are paid to or delivered to another, without consideration, an action lies against any one in whose hands they are found; and the law seems to be the same, though a consideration was given, if the party had previous notice of their being lost or stolen. Str. 505.

But the property of goods found or stolen, may be changed by sale for a valuable consideration, and without notice, in a market overt; and the party purchasing them obtains a title to them, against the original owner.

FINES, a mode of transferring property. By the ancient common law, a charter of feoffment was the only written instrument by which lands were conveyed; but the inconvenience sometimes arising from the loss of the charter, or the difficulty of proving it from a lapse of years, induced men to look out for some more secure and lasting assurance. For this purpose fines were adopted, that is, a fictitious process; a suit is instituted concerning the lands intended to be conveyed; and after the writ is issued and the parties appear in court, the suit is compounded with the consent of the judges, whereby the lands in question are acknowledged to be the right of one of the contending parties. This agreement is inrolled among the records of the court, and being substituted in the place of the sentence which would have been given had the action continued, is of equal force with the judgment of a court, puts an end not only to that suit but to all others respecting the same matter; a writ is then issued to the sheriff of the county in which the lands lie, in the same form as if judgment had been obtained, commanding him to deliver possession to the person who thus acquires the land, which renders the ceremony of livery of seisin unnecessary. We are indebted to the civilians for the first idea of this method of conveyance, by whom it was called *transactio*, and was introduced by the French into their law. A fine consists of five parts: 1st. The original writ; 2nd. The licencia concordandi; 3rd. The concord; 4. The note; 5. The foot. A fine can be levied on any writ which in any sort concerns lands, but the writ chiefly in use, is the writ of covenant. When the sheriff of the county where the lands lie is a party to the fine, the writ must be directed to the coroner; the licentia concordandi is the permission from the court to accommodate the suit. The concord comes in lieu of the sentence which would have been given had the action continued. The note is only the abstract of the writ of covenant, and the concord, naming the parties, the lands, and the agreement; and the foot chirograph or indenture includes the whole matter. Sir Edward Coke says, a fine is said to be levied when the writ of covenant is returned, and the concord duly entered. Fines are divided into executed and executory; and subdivided into, 1st. *Fines sur cognizance de droit comme ceo;* 2. *sur cognizance de droit tantum;* 3. *sur concessit;* and 4. *sur done grant et render.* A fine sur cognizance de droit comme ceo, &c. is the best and surest kind of fine, for thereby the deforciant in order to keep his covenant with the plantiff, of conveying to him the lands in question, and at the same time to avoid the formality of an actual feoffment and livery, acknowledges in court a former feoffment to have been made by him to the plaintiff, so that this assurance is rather a confession of a former conveyance, than a conveyance now originally made. A fine sur cognizance de droit tantum, is merely the acknowledgement of the right without the circumstance of a preceding gift from the cognizor, and

is commonly used to pass a reversionary interest which is in the cognizor. A fine sur concessit, is where the cognizor, though he acknowledges no precedent right, yet grants to the cognizee an estate de novo usually for life or years by way of supposed composition; and this may be done reserving a rent or the like, for it operates as a new grant. A fine sur done grant et render, is a double fine, comprehending the fine sur cognizance de droit comme ceo, and the fine sur concessit, and may be used to create particular limitations of estate; whereas the first conveys nothing but an absolute estate, and is the most used on that account: this is called a fine executed, and the others are but executory.

Fines were formerly levied in all the courts; but by Magna Charta they were usually thenceforth levied in the common pleas, and before two justices of that court; and the lord chief justice of the common pleas may alone take the acknowledgment of a fine out of court: but if he is a party to the writ, he cannot *quia judex in propria causa.* This rule extends to all our judges and commissioners. They are also taken by commissioners in the country, empowered by dedimus potestatem, who may be punished for abuses, and the fine taken before them set aside: and it may be levied of any things whereof a *precipe quod reddat* or *precipe quod faciat* lies, or a *precipe quod permittat* or *precipe quod teneat* may be brought. The force and effect of a fine depend principally on the common law, and the two statutes 4 Hen. VII. c. 24, and 32 Henry VIII. c. 36. The ancient common law as set forth in 18 Edward I. says, "the fine is so high a bar, and of so great force, and of a nature so powerful in itself, that it precludes not only those who are parties and privies to the fine, and their heirs, but all other persons in the world who are of full age, out of prison, of sound memory, and within the seas, the day of the fine levied, unless they put in their claim within a year and a day." But by a statute made in the reign of Edward I. persons were allowed to claim and falsify a fine at any indefinite time; but this giving rise to much contention and insecurity, a statute 6 Henry VII. wisely steered between the rigour of the common law and the latitude allowed by the former act, and limited the right of claim to five years, except femme-coverts, infants, prisoners, persons beyond the seas, or lunatics, who have five years after the death of their husbands, their attaining full age, recovering their liberty, or being restored to their right mind. The persons bound by a fine, are parties, privies, and strangers: the parties are the cognizors and cognizees, and all persons who may lawfully grant by deed may levy a fine, and this is almost the only act that a femme covert is allowed to do (when she is privately examined as to her voluntary consent), and is therefore the most usual and safe method whereby she can join in the sale, settlement, or incumbrance of any estate. Privies to a fine are such as are anywise related to the parties who levy the fine, and claim under them by any right of blood or other right of representation. Strangers to a fine are all other persons in the world except only parties and privies, who are also bound by a fine unless they prefer their claims within the space of five years. Persons who have not a present but future interest only have also five years allowed them to claim in from the time that right accrues; thus this conveyance not only binds the parties themselves and their heirs, but also all mankind whether concerned or no, if they fail to put in their claims within the time allowed by law.

Fines *for offences.* Originally all punishments were corporal; but after the use of money, when the profits of the courts arose from the money paid out of the civil causes, and the fines and confiscations in criminal ones, the commutation of punishments was allowed of; and the corporal punishment which was only in terrorem, changed into the pecuniary, whereby they found their own advantage. This begat the distinction between the greater and the less offences; for in the crimina majora there was at least a fine to the king, which was levied by a capiatur; but upon the less offences there was only an amercement, which was affeered, and for which a distringas, or action of debt only lay. 2 Bac. Abr. 502.

By the Bill of Rights 1 W. st. 2. c. 2. excessive fines ought not to be imposed; and all grants and promises of fines and forfeitures of particular persons, before conviction, are declared to be illegal and void. 4 Black. 379.

All courts of record may fine and imprison an offender, if the nature of the offence is such as deserves such punishment. 8 Co. 39. But no court, unless of record, can fine or imprison. 11 Co. 43. And all courts of law that have power given them to fine and imprison, are thereby made courts of record. 1 Salk. 200.

The sheriff in his torn, may impose a fine on all such as are guilty of any contempt in the face of the court; and may also impose what reasonable fine he shall think fitting, upon a suitor refusing to be sworn, or upon a bailiff refusing to make a panel, &c. or upon a tithingman neglecting to make his presentment, or upon one of the jury refusing to present the articles wherewith they are charged, or upon a person duly chosen constable refusing to be sworn. 2 Inst. 142.

Also the steward of a court-leet may by recognizance bind any person to the peace who shall make an affray in his presence, sitting the court; or may commit him to ward, either for want of sureties, or by way of punishment, without demanding any sureties of him; in which case he may afterwards impose a fine according to his discretion. F. N. B. 82.

Also the sheriff in his torn, and the steward of a court-leet, have a discretionary power either to award a fine or amercement for contempt of the court, for a suitor's refusing to be sworn, &c.; and the steward of a court-leet may either amerce or fine an offender, upon an indictment for an offence not capital, within his jurisdiction, without any farther proceeding or trial, especially if the crime was any way enormous, as an affray accompanied with wounding. Kitchin, 43, 51.

Some courts cannot fine or imprison, but amerce, as the county, hundred courts, &c. 11 Co. 43.

But some courts can neither fine, imprison, nor amerce; as ecclesiastical courts held before the ordinary, archdeacon, &c. or their commissaries, and such who proceed according to the canon or civil law. 11 Co. 44.

A fine may be mitigated the same term it was set, being under the power of the court during that time, but not afterwards. L. Raym. 376. And fines assessed in court by judgment upon an information, cannot be after-

wards mitigated. Cro. Car. 251. If a fine certain is imposed by statute on any conviction, the court cannot mitigate it; but if the party come in before conviction, and submit to the court, they may assess a less fine; for he is not convicted, and perhaps never might. The court of exchequer may mitigate a fine certain, because it is a court of equity, and they have a privy seal for it. 3 Salk. 33.

FINERS of gold and silver, are those who separate these metals from coarser ores.

FINERY, in the iron-works, one of the forges at which the iron is hammered and fashioned into what they call a bloom, or square bar.

FINGER, *in music*, a word metaphorically applied to ability in execution in general, but especially on keyed instruments; as when we say, such a master possesses an expressive or an elegant finger; that lady displays a rapid or a delicate finger.

Finger-board, that thin, black covering of wood laid over the neck of a violin, violoncello, &c. and on which, in performance, the strings are pressed by the fingers of the left hand, while the right manages the bow.

Fingering, disposing of the fingers in a convenient, natural, and apt manner in the performance on any instrument, but more especially the organ and piano-forte. Good fingering is one of the first things to which a judicious master attends. It is, indeed, to this that the pupil must look as the means for acquiring a facile and graceful execution, and the power of giving passages with articulation, accent, and expression. Easy passages may be rendered difficult, and difficult ones impracticable, by bad fingering; and though there are many arrangements of notes which admit of various fingering, still, even in these, there is always one best way of disposing of the hand, either with regard to the notes themselves, or those which precede or follow them. But there are an infinite number of possible dispositions of notes, which can only be fingered in one particular way; and every attempt at any other, is but endangering the establishment of some awkwardness, which the practitioner will have to unlearn before he can hope to attain the true fingering. Hence it is obvious, that no qualification requisite to good performance is of more importance to the learner than that of just fingering; and that whatever talents and assiduity may be able to achieve independent of instruction, in this great particular the directions of a skilful master are indispensable.

FINTO, in music (Ital.), a feint, a term applied to the preparation for a cadence which is not executed; when the performer having done every thing that is requisite to a full close, instead of falling on the final, passes to some other note, or introduces a pause.

FIR-tree. See Abies.

FIRE. See Caloric.

Fire, *wild*, a kind of artificial or factitious fire, which burns even under water. It is composed of sulphur, pitch, nitre, and various other combustible materials; and is very hard to extinguish. Chemistry, however, has supplied a still more destructive kind of wild-fire, in the union of nitrous acid with oil of turpentine. These two liquids separately are perfectly cold; but when suddenly mixed, produce a flame not easily extinguished. This, with great appearance of reason, is supposed to be the wild-fire of the ancients, who, inclosing the two liquids in a glass ball which had a partition to keep them asunder, threw the ball into some ship of the enemy's; and the globe being thus broken, the liquids united, and set the vessel in flames. The French call it Greek fire, or feu Gregois, because first used by the Greeks, about the year 660; as is observed by the jesuit Petavius, on the authority of Nicetas, Theophanes, Cedrenus, &c.

The inventor, according to the same jesuit, was an engineer of Heliopolis in Syria, named Callinicus, who first applied it in the sea-fight commanded by Constantine Pogonates against the Saracens, near Cyzicus, in the Hellespont; and with such effect, that he burnt the whole fleet in which were 30,000 men. But others will have it of a much older date; and hold Marcus Gracchus the inventor: which opinion is supported by several passages both in the Greek and Roman writers, which show it to have been anciently used by both these nations in their wars.

F. Daniel gives us a good description of the Greek fire in his account of the siege of Damietta under St. Louis. Every body, says that author, was astonished with the Greek fire, which the Turks then prepared, and the secret whereof is now lost. They threw it out of a kind of mortar; and sometimes shot it with an odd sort of cross-bow, which was strongly bent by means of a handle or winch, of much greater force than the mere arm. That thrown with the mortar sometimes appeared in the air of the size of a tun, with a long tail, and a noise like that of thunder. The French by degrees got the secret of extinguishing it, in which they succeeded several times.

Fire-place. Our ancestors, equally careless of fuel and patient of heat and of cold, basked before a large pile of burning wood with a screen at their backs; and in attempting to substitute a coal-fire, it was at first forgotten that bacon, &c. &c. was not to be hung in the chimney. Economical fire-places should be constructed on the following principles: 1. To place the grate as near the floor as may be. 2. To bring it as forward as may be, consistently with the proper situation of the throat of the chimney, which ought to be directly over the fire, and not larger than is sufficient to give free passage at all times to the smoke. 3. The mantle-piece should be as low as it can be without suffering from the heat, or obstructing the proper radiation of it into the room, from the fuel and flame. By these means, the feet and legs are easily warmed, and the face not so much incommoded; while a much greater volume of heated air is retained in a room of equal size than by high grates and large openings. Since it has been found that chimneys may be cleansed with long flexible brushes, why should they not be built of smaller diameter, circular, and smoothly plaistered within?

Fire, *machine for preserving from.* This machine consists of a pole, a rope, and a basket. The pole is of fir, or a common scaffold pole, of any convenient length from 36 to 40 feet; the diameter at bottom, or the greatest end, about five inches; and at the top or smallest end about three inches. At three feet from the top is a mortise through the pole, and a pulley fixed to it of nearly

the same diameter with the pole in that part. The rope is about three quarters of an inch diameter, and twice the length of the pole; with a spring hook at one end, to pass through the ring in the handle of the basket when used: it is put through the mortise over the pulley, and then drawn tight on each side near the bottom of the pole, and made fast there till wanted. The basket should be of strong wicker-work, three feet and a half long, two feet and a half wide, rounded off at the corners, and four feet deep, rounding every way at the bottom. To the top of the basket is fixed a strong iron curve or handle, with an eye or ring in the middle; and to one side of the basket, near the top, is fixed a small cord, or guide-rope, of about the length of the pole. When the pole is raised, and set against a house over the window from which any persons are to escape, the manner of using it is so plain and obvious, that it need not be described. The most convenient distance from the house for the foot of the pole to stand, where practicable, is about twelve or fourteen feet. If two strong iron straps, about three feet long, rivetted to a cross bar, and spreading about fourteen inches at the foot, were fixed at the bottom of the pole, this would prevent its turning round or slipping on the pavement. And if a strong iron hoop, or ferule, rivetted (or welded) to a semicircular piece of iron spreading about twelve inches, and pointed at the ends, was fixed on at the top of the pole, it would prevent its sliding against the wall.

When these two last-mentioned irons are fixed on, they give the pole all the steadiness of a ladder; and because it is not easy, except to persons who have been used to it, to raise and set upright a pole of forty feet or more in length, it will be convenient to have two small poles or spars of about two inches diameter, fixed to the sides of the great pole at about two or three feet above the middle of it, by iron eyes rivetted to two plates, so as to turn every way; the lower end of these spars to reach within a foot of the bottom of the great pole, and to have ferules and short spikes to prevent sliding on the pavement, when used occasionally to support the great pole like a tripod. There should be two strong ash-trundles let through the pole, one at four feet and one at five feet from the bottom, to stand out about eight inches on each side, and to serve as handles, or to twist the rope round in lowering a very heavy weight. If a block and pulley were fixed at about the middle of the rope, above the other pulley, and the other part of the rope made to run double, it would diminish any weight in the basket nearly one-half, and be very useful in drawing any person up, to the assistance of those in the chambers, or for removing any effects out of a chamber, which it might be dangerous to attempt by the stairs.

It has been proved, by repeated trials, that such a pole as we have been speaking of can be raised from the ground, and two or three persons taken out of the upper windows of a house, and set down safely in the street in the space of 35 seconds, or a little more than half a minute. Sick and infirm persons, women, children, and many others, who cannot make use of a ladder, may be safely and easily brought down from any of the windows of a house on fire by this machine, and by putting a short pole through the handles of the basket, may be removed to any distance without being taken out of the basket. The pole must always have the rope ready fixed to it, and may be conveniently laid up upon two or three iron hooks under any shade or gateway, and the basket should be kept at the watch-house. When the pole is laid up, the two spars should always be turned towards the head of it. The basket should be made of peeled rods, and the pole and spars painted of a light stone-colour, to render it more visible when used in the night.

Fire, *machines for extinguishing*. In the year 1734, the states of Sweden offered a premium of 20,000 crowns for the best method of stopping the progress of accidental fires; when one Mr. Fuches, a German physician, made a preparation for that end, and the experiment was tried on a house built on purpose, of dry fir, at Legard-island. In the building were placed several tubs of tar and pitch, and a great quantity of chips, all which were set on fire, flames issuing through the top of the house, windows, &c. when he threw in one of the barrels containing the preparation, which immediately quenched the flames; a second barrel entirely cleared the smoke away; and the whole was executed to the astonishment of the spectators, and to the no small satisfaction of the inventor, who was about to return home, when unexpectedly the flames broke out again, supposed to be occasioned by a small quantity of combustible matter being introduced and set on fire secretly by some malicious person. Upon this the wrongheaded mob fell upon Mr. Fuches, and beat him most unmercifully, so that he narrowly escaped with his life. He soon after left the country, and never could be prevailed on to return. Another experiment of this kind was tried in 1761 in Holland, but failed through the perverseness of the populace.

Attempts of a similar nature have met with a better reception in England. Of these the most successful was that of Mr. Godfrey, whose contrivance is thus described by Mr. Ambrose Godfrey, grandson to the inventor. "The material to be employed consists of a small portion of gunpowder closely confined; which, when animated by fire, acts by its elastic force upon a proper medium, and not only divides it into the minutest atoms, but disperses it also in every direction, so as immediately to extinguish any fire within a certain distance. This medium is a liquor strongly impregnated with a preparation of anticombustible principles, which by their action upon burning materials extinguish the flames, and reduce them in general to the state of a black coal; and, by its opposite nature to fire, hinders the remaining sparks, notwithstanding the admission of the air, from kindling the flames afresh. By this means, the great point is obtained, in giving sufficient time for totally extinguishing any remains of fire." From this account, however, nothing can be made out; and the quackery of concealment, in a matter that so nearly concerns the welfare of the human race, can only be accounted for on the score of its insufficiency, or the impossibility of making it generally useful.

The mode of employing these machines, was that of throwing them into the different rooms of the house in which the flames began to appear. Used in this way, if the invention really possessed the merit ascribed to it, it evidently would have been of great use in extin-

guishing fires on shipboard; and would probably have been considered as a no less necessary part of a ship's lading than her stores or ammunition.

Fire *in chimneys, method of extinguishing.* It is well known, that the inner parts of chimneys easily take fire; the soot that kindles therein emits a greater flame, according as the tunnel is more elevated, because the current of air feeds the fire. If this current could therefore be suppressed, the fire would soon be extinguished. In order to this, some discharge a pistol into the chimney, which produces no effect. Water thrown into the chimney at top is equally useless, because it comes down through the middle of the tunnel, and not along the sides. It would be more advisable to stop, with a wet blanket, the upper orifice of the tunnel; but the surest and readiest method is, to apply the blanket either to the throat of the chimney, or over the whole front of the fire-place. If there happens to be a chimney-board or a register, nothing can be so effectual as to apply them immediately; and having by that means stoppd the draught of air from below, the burning soot will be put out as readily and as completely as a candle is put out by an extinguisher, which acts exactly upon the same principle.

Fire, *securing buildings against.* Dr. Hales proposes to check the progress of fires by covering the floors of the adjoining rooms with earth. The proposal is founded on an experiment which he made with a fir-board half an inch thick, part of which he covered with an inch depth of damp garden-mold, and then lighted a fire on the surface of the mold; though the fire was kept up by blowing, it was two hours before the board was burnt through, and the earth prevented it from flaming. The thicker the earth is laid on the floors, the better: however, Dr. Hales apprehends that the depth of an inch will generally be sufficient: and he recommends to lay a deeper covering on the stairs, because the fire commonly ascends by them with the greatest velocity.

Mr. David Hartley made several trials in the years 1775 and 1776, in order to evince the efficacy of a method which he had invented for restraining the spread of fire in buildings. For this purpose, thin iron plates were well nailed to the tops of the joists, &c. the edges of the sides and ends being lapped over, folded together, and hammered close. Partitions, stairs, and floors, may be defended in the same manner; and plates applied to one side have been found sufficient. The plates are so thin as not to prevent the floor from being nailed on the joists, in the same manner as if this preventive was not used; they are kept from rust by being painted or varnished with oil and turpentine. The expense of this addition, when extending through a whole building, is reckoned at about five per cent. Mr. Hartley had a patent for this invention, and parliament voted a sum of money towards defraying the expense of his numerous experiments. The same preservative may also be applied to ships, furniture, &c. Mr. Hartley's patent has long since expired.

Earl Stanhope has also discovered and published a very simple and effectual method of securing every kind of building against fire. This method he has divided into three parts, viz. under-flooring, extra-lathing, and inter-securing. The method of under-flooring is either single or double. In single under-flooring, a common strong lath of oak or fir, about one fourth of an inch thick, should be nailed against each side of every joist, and of every main timber, supporting the floor which is to be secured. Other similar laths are then to be nailed along the whole length of the joists, with their ends butting against each other. The top of each of these laths or fillets ought to be at 1½ inch below the top of the joists or timbers against which they are nailed; and they will thus form a sort of small ledge on each side of all the joists. These fillets are to be well bedded in a rough plaister hereafter mentioned, when they are nailed on, so that there may be no interval between them and the joists; and the same plaister ought to be spread with a trowel upon the tops of all the fillets, and along the sides of that part of the joists which is between the top of the fillets and the upper edge of the joists. In order to fill up the intervals between the joists that support the floor, short pieces of common laths, whose length is equal to the width of these intervals, should be laid in the contrary direction to the joists, and close together in a row, so as to touch one another; their ends must rest upon the fillets, and they ought to be well bedded in the rough plaister, but are not to be fastened with nails. They must then be covered with one thick coat of the rough plaister, which is to be spread over them to the level of the tops of the joists; and in a day or two this plaister should be trowelled over close to the sides of the joists, without covering the tops of the joists with it.

In the method of double-flooring, the fillets and short pieces of laths are applied in the manner already described; but the coat of rough plaister ought to be little more than half as thick as that in the former method. Whilst this rough plaister is laid on, some more of the short pieces of laths above-mentioned must be laid in the intervals between the joists upon the first coat, and be dipped deep in it. They should be laid as close as possible to each other, and in the same direction with the first layer of short laths. Over this second layer of short laths there must be spread another coat of rough plaister, which should be trowelled level with the tops of the joists without rising above them. The rough plaister may be made of coarse lime and hair; or, instead of hair, hay chopped to about three inches in length may be substituted with advantage. One measure of common rough sand, two measures of slaked lime, and three measures of chopped hay, will form in general a very good proportion, when sufficiently beaten up together in the manner of common mortar. The hay should be put in after the two other ingredients are well beaten up together with water. This plaister should be made stiff; and when the flooring boards are required to be laid down very soon, a fourth or fifth part of quicklime in powder, formed by dropping a small quantity of water on the limestone a little while before it is used, and well mixed with this rough plaister, will cause it to dry very fast. If any cracks appear in the rough plaister-work near the joists when it is thoroughly dry, they ought to be closed by washing them over with a brush wet with mortar-wash; this wash may be prepared by putting two measures of quicklime and one of common

sand in a pail, and stirring the mixture with water till the water becomes of the consistence of a thick jelly.

Before the flooring-boards are laid, a small quantity of very dry common sand should be strewed over the plaister-work, and struck smooth with a hollow rule, moved in the direction of the joists, so that it may lie rounding between each pair of joists. The plaister-work and sand should be perfectly dry before the boards are laid, for fear of the dry rot. The method of under-flooring may be successfully applied to a wooden stair-case; but no sand is to be laid upon the rough plaister-work. The method of extra-lathing may be applied to ceiling joists, to sloping roofs, and to wooden partitions.

The third method, which is that of inter-securing, is very similar to that of under-flooring; but no sand is afterwards to be laid upon it. Inter-securing is applicable to the same parts of a building as the method of extra-lathing, but it is seldom necessary.

The author of this invention made several experiments, in order to demonstrate the efficacy of these methods. In most houses it is only necessary to secure the floors; and the extra expense of under-flooring, including all materials, is only about nine pence per square yard, and with the use of quicklime a little more. The extra expense of extra-lathing is no more than six pence per square yard for the timber side-walls and partitions; but for the ceiling about nine pence per square yard. But in most houses no extra-lathing is necessary.

Fire-flies, a species of flies in Guiana, of which there are two species. The largest is more than an inch in length, having a very large head connected with the body by a joint of a particular structure, with which sometimes it makes a loud knock, particularly when laid on its back. The fly has two feelers or horns, two wings, and six legs. Under its belly is a circular patch, which, in the dark, shines like a candle; and on each side of the head near the eyes is a prominent, globular, luminous body, in size about one-third larger than a mustard-seed. Each of these bodies is like a living star, emitting a bright, and not small, light; since two or three of these animals, put into a glass vessel, afford a light sufficient to read without difficulty, if placed close to the book. When the fly is dead, these bodies will still afford considerable light, though it is less vivid than before; and if bruised, and rubbed over the hands or face, they become luminous in the dark, like a board smeared over with English phosphorus. They are of a reddish-brown or chesnut colour; and live in rotten trees in the day, but are always abroad in the night. The other kind is not more than half as large as the former: their light proceeds from under their wings, and is seen only when they are elevated, like sparks of fire appearing or disappearing at every second. Of these the air is full in the night, though they are never seen in the day. They are common not only in the southern, but in the northern parts of America during summer.

Fire-ball, in the art of war, a composition of meal-powder, sulphur, saltpetre, pitch, &c. about the bigness of a hand-grenade, coated over with flax, and primed with a slow composition of a fuse. This is to be thrown into the enemy's works in the night time, to discover where they are: or to fire houses, galleries, or blinds of the besiegers; but they are then armed with spikes or hooks of iron, that they may not roll off, but stick or hang where they are designed to have effect.

Fire-bote, is fuel or firing for necessary use, allowed to tenants, out of the lands granted to them.

Fire-irons. These are too well known to need description: they are, however, mentioned, to notice a patent taken out by Mr. Bentham, for the improvement of them, by making all the parts that admit of it tubular instead of solid.

Fire-pots, in the military art, small earthen pots, into which is put a charged grenade, and over that powder enough till the grenade is covered; then the pot is covered with a piece of parchment, and two pieces of match across lighted: this pot being thrown by a handle of match, where it is designed, it breaks and fires the powder, and burns all that is near it, and likewise fires the powder in the grenade, which ought to have no fuse, that its operations may be the quicker.

FIRES and Firecocks. By 14 G. III. c. 78, church-wardens in London, and within the bills of mortality, are to fix firecocks, &c. at proper distances in streets and keep a large engine and hand-engine for extinguishing fire, under the penalty of ten pounds. And to prevent fires, workmen in the city of London, &c. must erect party-walls between buildings, or brick or stone of a certain thickness, &c. under penalties therein mentioned.

On the breaking out of any fire, all the constables and beadles shall repair to the place with their staves, and be assisting in putting it out, and causing people to work. No action lies against a person in whose house or chamber a fire accidentally begins.

Fire-ships, in the navy, are vessels charged with combustible materials or artificial fireworks; which having the wind of an enemy's ship, grapple her, and set her on fire.

Anderson, in his History of Commerce, vol. 1, p. 432, ascribes the invention to the English, in this instance, viz. some vessels being filled with combustible matter, and sent among the Spanish ships composing the Invincible Armada, in 1588; and hence arose, it is said, the terrible invention of fire-ships.

But Livy informs us, that the Rhodians had invented a kind of fire-ships, which were used in junction with the Roman fleet in their engagement with the Syrians, in the year 190 before Christ: cauldrons of combustible and burning materials were hung out at their prows, so that none of the enemy's ships durst approach them; for these fell on the enemies' galleys, struck their beaks into them, and at the same time set them on fire.

Firelocks, so called from their producing fire of themselves, by the action of the flint and steel; the arms carried by a foot-soldier. They were formerly three feet eight inches in the barrel, and weighed fourteen pounds; at present the length of the barrel is from three feet three inches to three feet six inches, and the weight of the piece only twelve pounds. They carry a leaden bullet of which 29 make 2lb. its diameter is .550 of an inch, and that of the barrel 1-50th part of the shot. Firelocks were first made use of in 1690, when matchlocks were universally disused; but when invented, we cannot ascertain. A firelock is called, by writers of about the middle of the last century, asnaphaan, which being a

Low-Dutch word, seems to indicate its being a Dutch invention.

Fire works. In England it is not lawful for any person to make or cause to be made, or sell or expose to sale, any squibs, rockets, serpents, or other fireworks; or any cases, moulds, or other implements for making the same; or to permit the same to be cast or fired from his house or other place thereto belonging, into any public street or road; or to throw or fire, or be aiding in throwing and firing the same, in any public street, house, shop, river, or highway; and every such offence shall be adjudged a common nuisance. 9 and 10 W. c. 7.

FIRING *in line*, in the military art. According to regulations, the following principal heads constitute firing in line.

The object of fire against cavalry is to keep them at a distance, and to deter them from the attack; as their movements are rapid, a reserve is always kept up. But when the fire commences against infantry, it cannot be too heavy, or too quick while it lasts; and should be continued till the enemy is beaten or repulsed. This may not improperly be called offensive fire.

Defensive fire belongs principally to infantry, when posted on heights, which are to be defended by musquetry. As soldiers generally present too high, and as fire is of the greatest consequence to troops that are on the defensive, the habitual mode of firing should therefore be rather at a low level than a high one.

On these occasions the men are generally drawn up three deep; in which case the front rank kneeling, being the most efficacious as being the most raising, should not be dispensed with when it can be safely and usefully employed.

Firing *by half-battalions, the line advancing*. The left wings halt, and the right ones continue to march 15 paces, at which instant the word march being given to the left wings, the right at the same time are ordered to halt, fire, and load, during which the left march on and pass them till the right wings, being loaded and shouldered, receive the word march, on which the left ones halt, fire, &c. and thus they alternately proceed.

Firing *by half-battalions, the line retiring*. The right wings are ordered to halt, front, and when the left wings have gained fifteen paces, and have received the word halt, front, the right wings are instantly ordered to fire, load, face about, and march fifteen paces beyond the left ones, where they receive the word halt, front, on which the left wings fire, &c. and thus alternately proceed.

It is observed in the official rules and regulations, that in addition to the battalion directions, there must be a regulating battalion named, by the half-battalions of which each line will move, halt, and fire: the commander of each line will be with such half-battalion, and in giving his several commands must have an attention to the general readiness of the line, especially after loading, that the whole are prepared to step off together at the word march. The firing of the advanced wing succeeds the march, or the halt, front, of the retired wing instantly; and each half-battalion fires independant and quick, so that no unnecessary pauses being made betwixt the firing words, the fire of the line should be that of a volley as much as possible; and the whole being thereby loaded together, will be ready for the next command of movement. In these firings of the line advancing or retiring, the two first ranks will fire standing, and the rear rank support their arms.

In this manner also may the alternate battalions of a line advance or retire, and when the whole are to form, and that the last line moves up to the first, every previous help of advanced persons will be given to ensure its correctness.

Fire *in line advancing*, is when the infantry marches in line to attack the enemy, and in advancing makes use of its fire. On these occasions it is better to fire the two first ranks only standing, reserving the third, than to make the front rank kneel and to fire the whole; but when it is necessary to fire at a considerable distance, or on a retiring enemy, volleys may be given by the three ranks, the front one kneeling.

Firing *by platoons*, is practised when a line is posted, or arrives at a fixed situation. In this position, battalions fire independantly of one another, and the fire generally commences from the centre of each. The first fire of each battalion must be regular, and at established pauses and intervals; after which each platoon may continue to fire as soon as it is loaded, independant, and as quick as possible.

Firing *by files*, is generally used behind a parapet, hedge, or abbatis. In this situation the two first ranks only can fire, and that must be by the two men of the same file always firing together, with coolness and deliberation. When, however, the parapet hedge, or abbatis, is but a little raised, platoon firing may be resorted to.

Olique Firing *by battalions*, or otherwise, according to the ground, is extremely advantageous when it is found expedient to give an oblique direction to part of a line, or when it is discovered that their fire can in this manner be thrown against the opening of a defile, the flanks of a column, or against cavalry or infantry that direct their attack on some particular battalion or portion of the line.

Oblique-firing, is either to the right and left, or from the right and left to the centre, depending entirely on the situation of the object to be fired against. The Prussians have a particular contrivance for this purpose: if they are to level to the right, the rear ranks of every platoon are to make two quick but small paces to the left, and the body of each soldier to turn 1-8th of a circle; and are to take the same distance to the right, if they are to level to the left.

When a line halts at its points of firing, no time is to be lost in scrupulous dressing, and the firing is instantly to commence. But when a line halts, and is not to fire, the usual dressings must be attended to; and every thing will depend upon the coolness and attention of the officers and non-commissioned officers.

It should be observed with respect to firings in general, that after the march in front, and halt of the battalion, company or platoon firing ought invariably to begin from the centre, and not from the flank. In other cases, and in successive formations, it may begin from whatever division first arrives, and halts on its own ground.

Square-Firing, is that method of firing where either a regiment or any body of men are drawn up in a square, each front of which is generally divided into four divi-

sions or firings, and the flanks of the square, as being the weakest part, are sometimes covered by four platoons of grenadiers who flank the angles. The first fire is from the right division of each face, the second fire from the left divison of each face, and so on; the grenadiers making the last fire.

Street-FIRING, is the method of firing adopted to defend or scour a street, lane, or narrow pass of any kind; in the execution of which the platoon must be formed according to the width of the place, leaving sufficient room on the flanks for the platoons which have fired, successively to file round to the rear of the others.

Street-FIRING *advancing*. When the column has arrived at the spot where the firing is to commence, the commanding officer from the rear gives the word halt; and the officer commanding the platoon, orders it to make ready, p'sent, fire; recover arms, out-wards face (by half-platoons), quick march.

At the instant the men in the first platoon recover their arms after firing, the second platoon makes ready, and waits in that position till the front is cleared by the first platoon having filed round the flanks towards the rear, when the second advances, with recovered arms, until it receives the word halt, p'sent, fire.

As soon as the platoon which has fired, has got down the flanks, it must form in front of the colours, and prime and load.

Street FIRING *retiring*, is conducted on the same principles, except that the platoons fire without advancing, on the front being cleared by the former platoon filing round the flank.

Another method of street-firing, advancing, generally esteemed more eligible, is, after firing, to wheel out by subdivisions (the pivots having taken a side step to right and left outwards), prime and load, and as soon as the last platoon has passed, file inwards and form.

FIRKIN, an English measure of capacity, for things liquid, being the fourth part of the barrel: it contains 8 gallons of ale, soap, or herrings: and 9 gallons of beer.

FIRLOT, a dry measure used in Scotland. The oat-firlot contains $21\frac{1}{4}$ pints of that country; the wheat-firlot contains about 1211 cubic inches; and the barley-firlot 31 standard pints. Hence it appears that the Scotch wheat-firlot exceeds the English bushel by 33 cubic inches.

FIRST, a word applied to the upper part in a duet, trio, quartet, &c. either vocal or instrumental; also to the upper part of each kind in overtures, symphonies, concertos, and other full pieces. Such parts are called first, because they generally express the air; and from their superior acuteness possess a pre-eminence in the combined effect.

In the score the first part always occupies the stave immediately above that in which the second is written; the second, the stave immediately over that which contains the third, and so on.

FIRST-FRUITS and TENTHS. First fruits are the profits of every spiritual living, for one year, and tenths are the tenth part of the yearly value of such living, given anciently to the pope through all Christendom; but by stat. 26 H. VIII. c. 3, translated to the king, in England, for the ordering whereof there was a court erected, 32 H. VIII. c. 45, but again dissolved anno primo Mariæ, sess. 2. c. 10. And since that time, though these profits are reduced again to the crown, by the stat. 1 Eliz. c. 4, yet was the court never restored, but all matters therein wont to be handled, were transferred to the exchequer.

By stat. 26 H. VIII. the lord chancellor, bishops, &c. are empowered to examine into the value of every ecclesiastical benefice and preferment in their several dioceses; and every clergyman entered on his living before the first-fruits are paid or compounded for, is to forfeit double value. But stat. 1 Eliz. c. 4, ordains, that if an incumbent on a benefice does not live half a year, or is ousted before the year expires, his executors are to pay only a fourth part of the first-fruits; and if he lives the year and then dies, or is ousted in six months after, but half the first-fruits shall be paid; if a year and a half, three quarters of them; and if two years, then the whole; not otherwise. The archbishops and bishops have four years allowed for the payment, and shall pay one quarter every year, if they live so long upon the bishopric: other dignitaries in the church, pay theirs in the same manner, as rectors and vicars.

By 27 H. VIII. c. 8, no tenths are to be paid for the first year, as then the first fruits are due; and by several statutes of Anne, if a benefice is under fifty pounds per annum, clear yearly value, it shall be discharged of the payment of first-fruits and tenths.

The queen also restored to the church, what at first had been thus indirectly taken from it, by remitting the tenths and first-fruits entirely, but by applying these superfluities of the larger benefices, to make up the deficiencies of the smaller; for this purpose she granted a charter, whereby all the revenue of the first-fruits and tenths is vested in trustees for ever, to form a perpetual fund for the augmentation of poor livings under 50*l.* a year. This is usually called queen Anne's bounty, which has been still further regulated by subsequent statutes: though it is to be lamented that the number of such poor livings is so great, that this bounty, extensive as it is, will be slow, and almost imperceptible in its operation; the number of livings under 50*l.* certified by the bishops, at the commencement of the undertaking, being 5597, the revenues of which, on a general average, did not exceed 23*l.* per annum. Black. 285, 286.

FISC, in the civil law, the treasury of a prince. It differs from the ærarium, which was the treasury of the public or people: thus, when the money arising from the sale of condemned persons' goods was appropriated for the use of the public, their goods were said publicari; but when it was destined for the support of the prince, they were called confiscari.

FISCAL, in the civil law, something relating to the pecuniary interest of the prince or people. The officers appointed for the management of the fisc, were called procuratores fisci, and advocati fisci; and among the cases enumerated in the constitutions of the empire, where it was their business to plead, one is against those who have been condemned to pay a fine to the fisc on account of their litigiousness, or frivolous appeals.

FISH, in natural history, constitutes a class of animals which have no feet, but always fins; add to this, that their body is either altogether naked, or only covered

with scales; and that they are aquatic animals, which live mostly, if not always, in water.

They form the 4th class of animals in the Linnæan system, and are divided into six orders, viz. the apodes, the jugulares, the thoraci i, the abdominales, the branchiostegous, and chrondropterygious. See NATURAL HISTORY, PISCES, &c. The animals included in this class are always inhabitants of the waters; are swift in their motions, and voracious in their appetites. They breathe by means of gills, which are generally united by a bony arch, swim by means of radiate fins, and are mostly covered with cartilaginous scales. Besides the parts which they have in common with other animals, they are furnished with a nictitant membrane, and most of them with an air-bladder, by the contraction and dilatation of which, they can raise or sink themselves at pleasure. They are destitute of eyelids, external ears, neck, arms and legs. Their food is mucus, insects, dead bodies, lesser sea-fish, and sea-plants.

The generic character is taken from the shape of the body, covering, structure, figure, and parts of the head; but principally from the branchiostegous membrane. The specific character is taken from the cirri, jaws, fins, spines, lateral lines, digitated appendages, tail and colour. The age of fishes is known by numbering the concentric circles in a transverse section of the backbone, or the concentric circles on the scales. The characters of the six orders are, (1.) apodal, without ventral fins: (2.) jugular, ventral fins before the pectoral: (3.) thoracic, ventral fins under the pectoral: (4.) abdominal, ventral fins behind the pectoral: (5.) branchiostegous, gills destitute of bony rays: (6.) chondropterygious, gills cartilaginous. These two latter orders Linnæus refers to the class amphibia nantes; so that in fact he admits of only 4 orders: under these he enumerates 189 genera, and about 400 species.

FISH. Any person may erect a fish-pond without licence; because it is a matter of profit, and for the increase of victuals. 2 Inst. 199.

Concerning the right and property of fish, it has been held, that where the lord of the manor has the soil on both sides of the river, it is good evidence that he has the right of fishing; but where the river ebbs and flows, and is an arm of the sea, there it is common to all, and he who claims a privilege to himself must prove it. In the Severn, the soil belongs to the owners of the land, on each side; and the soil of the river Thames is in the king, &c. but the fishing is common to all. 1 Mod. 105.

Any person who shall unlawfully break, cut, or destroy, any head or dam of a fish-pond, or wrongfully fish therein, with intent to take or kill fish, shall on conviction at the suit of the king, or of the party, at the assizes or sessions, be imprisoned three months, and pay treble damages, and after the expiration of the three months, shall find sureties for his good behaviour for seven years, or remain in prison till he does. 5 Eliz. c. 21.

If any person shall enter into any park or paddock, fenced in and enclosed, or into any garden, orchard, or yard, adjoining or belonging to any dwelling-house, in or through which park or paddock, garden, orchard, or yard, any stream of water shall run, or wherein shall be any river, stream, pond, pool, moat, stew, or other water, and by any means or device whatsoever, shall steal, take, kill, or destroy, any fish bred or kept in it, without the consent of the owner, or shall be aiding therein, or shall receive or buy any such fish, knowing them to be so stolen or taken as aforesaid, and shall be convicted thereof at the assizes, within six calendar months after the offence shall be committed, he shall be transported for seven years. And any offender, surrendering himself to a justice, or being apprehended or in custody for such offence, or on any other account, who shall make confession thereof, and a true discovery on oath of his accomplice or accomplices, so that such accomplice may be apprehended, and shall on trial give evidence, so as to convict such accomplices, shall be discharged of the offence, so by him confessed.

And if any person shall take, kill, or destroy, or attempt to take, kill, or destroy, any fish in any river, or stream, pond, pool, or other water, (not in any park or paddock, or in any garden, orchard, or yard, adjoining or belonging to any dwelling-house, but in any other inclosed ground, being private property) he shall, on conviction before one justice, on the oath of one witness, forfeit 5*l.* to the owner of the fishery of such river, pond, or other water; and such justice, on complaint upon oath, may issue his warrant to bring the person complained of before him; and if he shall be convicted before such justice, or any other of the county or place, he shall immediately pay the said penalty of 5*l.* to such justice, for the use of the person, as the same is appointed to be paid unto; and in default thereof, shall be committed by such justice to the house of correction, for any time not exceeding six months, unless the forfeiture shall be sooner paid: or such owner of the fishery may, within six calendar months after the offence, bring an action for the penalty in any of the courts of record at Westminster. 5 G. III. c. 14.

FISH, in a ship, a plank or piece of timber, fastened to a ship's mast or yard to strengthen it, which is done by nailing it on with iron spikes, and woulding or winding ropes hard about them.

FISH, *royal*, these are whale and sturgeon, which the king is entitled to, when either are thrown on shore, or caught near the coasts. Plowd. 315.

FISHES, in heraldry, are the emblems of silence and watchfulness, and are borne either upright, embowed, extended, endorsed respecting each other, surmounting one another, fretted, &c. In blazoning fishes, those borne feeding, should be termed devouring; all fishes borne upright and having fins, should be blazoned hauriant; and those borne transverse the escutcheon, must be termed naiant.

FISH-PONDS, those made for the breeding or feeding of fish.

Fish-ponds are no small improvement of watery and boggy lands, many of which are fit for no other use. In making of a pond, its head should be at the lowest part of the ground, that the trench of the flood-gate or sluice, having a good fall, may not be too long in emptying: The best way of making the head secure, is to drive in two or three rows of stakes above six feet long, at about four feet distance from each other, the whole length of the pond-head, of which the first row should be rammed at least about four feet deep. If the bottom is false, the foundation may be laid with quicklime, which slacking, will make it as

hard as a stone. Some lay a layer of lime, and another of earth dug out of the pond, among the piles and stakes; and when these are well covered, drive in others, as they see occasion, ramming in the earth as before, till the pond-head is of the height designed.

The dam should be made sloping on each side, leaving a waste to carry off the over-abundance of water in times of floods or rains; and as to the depth of the pond, the deepest part need not exceed six feet, rising gradually in shoals towards the sides, for the fish to sun themselves, and lay their spawn. Gravelly and sandy bottoms, especially the latter, are best for breeding; and a fat soil, with a white fat water, as the washings of hills, commons, streets, sinks, &c. is best for fattening all sorts of fish. For storing a pond, carp is to be preferred for its quick growth, and great increase, as breeding five or six times a year; but tench for its goodness.

The quantity of fish to be supplied obviously depends upon the quantity of water, which should be divided, where it conveniently can, into five ponds.

Number 5 is intended for breeding, and should be double or treble the size of any of the other ponds. Or if this be inconvenient, there may be two for this purpose. This pond may likewise be the most distant from the house. If the breeding pond should fail to answer this purpose, it will at least serve as a conservatory for fish of small size, to be obtained elsewhere: and indeed, fresh stores in any case will be found desirable. The contents of this pond in carp and tench, or the greatest part, should be taken out annually in September or October, counted in braces, and such as are from five to seven inches long thrown into the pond called No. 4.

The contents of No. 4, when grown one year from the length of five or seven inches, must be put into No. 3. The contents of No. 3, having grown one year from No. 4, must be removed into No. 2. And in like manner, the contents of No. 2, after one year, must be removed into No. 1, which is to contain only such fish as are fit for the table. It is obvious that this pond, for safety and convenience, should be the nearest to the house.

As No. 5 is to be the largest water, so No. 1 is to be the least; the rest of sizes between the two.

The shape of No. 1 should be oblong, for the convenience of the net, and the less disturbance of the fish in taking out what are wanted from time to time.

A book should be kept of the number and size of each kind in every pond.

Carp are fit for the table from three to seven pounds each. Tench from one pound and a half to three pounds each. Perch from three quarters of a pound to one or two pounds, &c.

It is supposed that none of the ponds have a strong current of very cold, acrid, innutritious water.

One acre of water upon a loam, clay, or marl, or any of these with a mixture of gravel, has been st ted to be capable of supporting 2000 pounds weight of fish; the number of the fish making that weight being immaterial.

Carp and tench breed most freely in ponds, or pits newly made. Tench likewise in almost any ponds, where cattle are admitted.

It is evident that perch and pike should not be admitted in any degree in No. 5; but in all the other numbers, besides their own value, they are of important service, provided that they are strictly confined to a size greatly subordinate to that of the carp, or tench. For they destroy not only the accidental spawn of fish which breed, but also several animals, whose food is the same with that of carp and tench, as frogs, newts, &c. Pike above the weight of one or two pounds must not be admitted even amongst carp of the largest size and weight.

With regard to the absolute weight of fish, which any particular pond will support, this can only be determined by observation and experience; as it depends on the different degrees of nutrition in different waters. It is said, that carp and tench in waters which feed well, will before they are aged, double their weight in one year.

The third part of an acre in No. 1 would probably be sufficient for the demand of any family. For, upon the calculation above given, it would support near 700 pounds of fish, which might be divided thus.

50 brace of carp of three pounds each and upwards.
50 brace of tench, of two pounds each and upwards.
50 brace of perch, of one pound each and upwards.

That is, three brace of fish, weighing at least twelve pounds, for the use of every week.

Allowing one acre for No. 5, one-third of an acre for No. 1, and one acre and two-thirds for the intervening numbers, the whole water would be three acres. Upon this calculation the stock of No. 1 at 8*d.* per pound, would be worth 23*l.* 6*s.* 8*d.* per annum, and the expense annually of changing the fish from No. 5 to 4, &c. will not exceed 1*l.* 6*s.* 8*d.* So that the value of each acre would be at lowest 7*l.* 6*s.* 8*d.* annually.

No. 1 being supposed to be near the house, and at no great distance from the garden, if the fish should not thrive sufficiently, which will be seen by the disproportioned size of the head, and the whiteness or paleness of the scales, they may easily be supplied with more food by loose peas from the garden, the sweeping of the granary, worms saved by the gardener in digging, and the offal of the poultry killed for the kitchen; or by letting down the water about two feet, in the spring or summer, where there is a sufficient supply, and sowing the sides with oats, barley, rye, or wheat, very lightly raked in, and then stopping the sluice again.

In ponds already stocked, but not accurately regulated, it would be advisable to begin with that which has the most pike, otherwise with No. 4, or what is intended for No. 4, and throw all the fish under five inches length into No. 5, and the larger, according to their sizes, into the other numbers: and so on with No. 3, 2, 1.

Store-fish procured elsewhere, if taken in summer, should be moved in the night in clean straw, wetted occasionally after they are packed: except perch and pike, which can only be carried in clean pond or river water. In moving fish from one pond to another, they should be first put into tubs of water already prepared for them, and afterwards carried in buckets without water. In taking pike or perch, great care must be observed to avoid raising mud in the water.

In breeding-ponds, all water-fowls, as geese, ducks, &c. should be discouraged; and herons carefully destroyed. If any white fish, as roach, dace, &c. should be found, they are to be taken out; and if there is a spare piece of water for large pike they should be put into it as food for the pike.

Eels may be put with advantage into any except the breeding-ponds, in lieu of perch. The most easy way of taking them is by trimmers laid over night, baited with small fish, not with worms; otherwise they may catch the carp; or a small thief-net may be baited with white fish.

Common sewers and drains from the laundry are prejudicial to fish: so are the leaves falling from trees in great quantities. The use of grains should likewise be avoided in large quantities, as having little nutriment whilst they are thus washed with water.

It seems better for the use of the table, as well as more humane, to kill fish designed for food by an incision with a sharp-pointed penknife, or punctures made with a pin longitudinally into the brain, about half an inch or an inch, according to the size of the fish, above the eyes. As this produces an instantaneous effect, it would probably save the cruel operation of crimping or flaying fish while alive, as in the case of pike and eels.

It is obvious, that this method of regulating fish will apply with its full effect in larger spaces of water: it will likewise apply in a considerable degree to smaller pieces, even where the change is but from a pond for the use of cattle to a single canal in a garden.

In situations near the great inland manufactures, and near the turnpike roads leading from an easy distance to the metropolis, water may be made by this kind of management, with little trouble or expense, to produce a large annual rent.

FISHERMEN. There shall be a master, wardens, and assistants of the fishmongers' company in London chosen yearly, at the next court of the lord mayor and aldermen after the 10th of June, who are constituted a court of assistants; and they shall meet once a month at their common hall to regulate abuses in fishery, register the names of fishermen, and mark their boats, &c.

FISHERY, a place where great numbers of fish are caught.

The principal fisheries for salmon, herring, mackrel, pilchards, &c. are along the coasts of England, Scotland, and Ireland; for cod, on the banks of Newfoundland; for whales, about Greenland; and for pearls, in the East and West Indies.

Fishery, *free*, in law, or an exclusive right of fishing in a public river, is a royal franchise; and is considered as such in all countries where the feodal polity has prevailed: though the making such grants, and by that means appropriating, what it seems unnatural to restrain, the use of running water, was prohibited for the future by Magna Charta; and the rivers that were fenced in king John's time were directed to be laid open, as well as the forests, to be disforested. This opening was extended by the second and third charters of Henry III. to those also that were fenced under Richard I.; so that a franchise of free fishery ought now to be as old at least as the reign of Henry II. This differs, as judge Blackstone observes, from a several of piscary, because he that has a several fishery must also be the owner of the soil, which in a free fishery is not requisite. It differs also from a common fishery, in that the free fishery is an exclusive right; the common is not so; and therefore, in a free fishery, a man has a property in the fish before they are caught; in a common piscary, not till afterwards. Some indeed have considered a free fishery not as a royal franchise, but merely as a private grant of a liberty to fish in the several fishery of the grantor. But the considering such right as originally a flower of the prerogative, till restrained by Magna Charta, and derived by royal grant (previous to the reign of Richard I.) to such as now claim it by prescription, may remove some difficulties in respect to this matter with which our law-books are embarrassed.

Fishery, denotes also the commerce of fish, more particularly the catching them for sale. Were we to enter into a very minute consideration of the fisheries established in England, this article would swell beyond its proper bounds; since fisheries, however, if successful, are not only objects of great commercial importance, but also contribute materially to naval strength, by becoming permanent nurseries for seamen, we shall take notice of some of the most considerable of the British fisheries, and the institutions set on foot for their support.

The situation of the British coasts is the most advantageous in the would for catching fish: the Scottish islands, particularly those to the north and west, lie most commodious for carrying on the fishing trade to perfection. Of these advantages the Scots seem indeed to have been abundantly sensible; for their traffic in herrings is even noticed in history so early as the ninth century. The frequent laws which were enacted in the reigns of James III. IV. and V. discover a steady determined zeal for the benefit of the country, and the full restoration of these fisheries, which the Dutch had found means to engross.

The Scottish fisheries were, however, more particularly indebted to the zealous encouragement of James V. and VI.; the former having planned, and the latter carried into execution, various projects for their extension. The well-meant efforts of James VI. were impeded, and at last wholly suspended, by the disputes which prevailed in the kingdom at that period concerning the succession. Nevertheless the plan was resumed by Charles I. who "ordained an association of the three kingdoms, for a general fishing within the seas and coasts of his majesty's said kingdom; and for the government of the said association, ordained, that there should be a standing committee chosen and nominated by his majesty and his successors from time to time," &c. Several persons of distinction embarked in the design, which the king honoured with his patronage, and encouraged by his bounty. He also ordered Lent to be more strictly observed; prohibited the importation of fish taken by foreigners; and agreed to purchase from the company his naval stores, and the fish for his fleets. Thus the scheme for establishing a fishery in the Hebrides began to assume a favourable aspect; but all the hopes of the adventurers were frustrated by the breaking out of the civil wars, and the very tragical death of their benefactor.

In 1661, Charles II., the duke of York, lord Clarendon, and other persons of rank and fortune, resumed the business of the fisheries with greater vigour than any of their predecessors. For this purpose, the most salutary laws were enacted by the parliaments of England and Scotland; in virtue of which, all materials used in, or depending upon, the fisheries, were exempted from

all duties, excises, or imposts whatever. In England, the company were authorised to set up a lottery, and to have a voluntary collection in all parish churches. Houses of entertainment, as taverns, inns, ale-houses, were to take one or more barrels of herrings, at the stated price of 30*s.* per barrel: also 2*s.* 6*d.* per barrel Dutch was to be paid to the company on all imported fish taken by foreigners. Some families were also invited, or permitted, to settle at Stornaway: the herrings cured by the royal English company gave general satisfaction, and, as mentioned above, brought a high price for those days. Every circumstance attending this new establishment seemed the result of a judicious plan and thorough knowledge of the business, when the necessities of the king obliged him to withdraw his subscription or bounty; which gave such umbrage to the parties concerned, that they soon after dissolved.

In 1677, a new royal company was established in England, at the head of which were the duke of York, the earl of Derby, &c. Besides all the privileges which former companies had enjoyed, the king granted this new company a perpetuity, with power to purchase lands; and also 20*l.* to be paid them annually, out of the customs of the port of London, for every dogger or buss they should build and send out for seven years to come. A stock of 10,980*l.* was immediately advanced, and afterwards 1600*l.* more. This small capital was soon exhausted in purchasing and fitting out busses, with other incidental expenses. The company made, however, a successful beginning; and one of their busses or doggers actually took and brought home 32,000 cod fish; other vessels had also a favourable fishery. Such flattering beginnings might have excited fresh subscriptions, when an unforeseen event ruined the whole beyond the possibility of recovery. Most of the busses had been built in Holland, and manned with Dutchmen; on which pretence the French, who were then at war with Holland, seized six out of seven vessels, with their cargoes and fishing-tackle: and the company being now in debt, sold in 1680 the remaining stores, &c. A number of gentlemen and merchants raised a new subscription of 60,000*l.* under the privileges and immunities of the former charter. This attempt also came to nothing, owing to the death of the king, and the troubles of the subsequent reign.

Soon after the Revolution the business was again resumed upon a more extensive scale; the proposed capital being 300,000*l.* of which 100,000*l.* was to have been raised by the surviving patentees or their successors, and 200,000*l.* by new subscribers. Copies of the letters patent, the constitution of the company, and terms of subscription, were lodged at sundry places in London and Westminster for the perusal of the public, while the subscription was filling. It is probable that king William's partiality to the Dutch fisheries, the succeeding war, or both of these circumstances, frustrated this new attempt; of which we have no farther account in the annals of that reign or since.

The Scottish parliament had also, during the last three reigns, passed various acts for erecting companies and promoting the fisheries; but the intestine commotions of that country, and the great exertions which were made for the Darien establishment, enfeebled all other attempts, whether collectively or by individuals, within that kingdom.

In 1749, his late majesty, having, at the opening of the parliament, warmly recommended the improvement of the fisheries, the house of commons appointed a committee to inquire into the state of the herring and white fisheries, and to consider of the most probable means of extending the same. All ranks of men were elevated with an idea of the boundless riches that would flow into the kingdom from this source. A subscription of 500,000*l.* was immediately filled in the city, by a body of men who were incorporated for 21 years by the name of The Society of the Free British Fishery. Every encouragement was held out by government, both to the society and to individuals, who might embark in this national business. A bounty of 36*s.* per ton was to be paid annually out of the customs, for 14 years, to the owners of all decked vessels or busses, from 20 to 80 tons burden, which should be built after the commencement of the act, for the use of, and fitted out and employed in, the said fisheries, whether by the society or any other persons. At the same time numerous pamphlets and newspaper-essays came forth; all pretending to elucidate the subject, and to convince the public with what facility the herring-fisheries might be transferred from Dutch to British hands. This proved, however, a more arduous task than had been foreseen by superficial speculators. The Dutch were frugal in their expenditures and living; perfect masters of the arts of fishing and curing, which they had carried to the greatest height and perfection. They were in full possession of the European markets; and their fish, whether deserving or otherwise, had the reputation of superior qualities to all others taken in our seas. With such advantages, the Dutch not only maintained their ground against this formidable company, but had also the pleasure of seeing the capital gradually sinking, without having procured an adequate return to the adventurers; notwithstanding various aids and efforts of government from time to time in their favour, particularly in 1757, when an advance of 20*s.* per ton was added to the bounty.

In 1786 the public attention was again called to the state of the British fisheries, by the suggestions of Mr. Dempster in the house of commons, and by different publications that appeared upon the subject; in consequence of which, the minister suffered a committee to be named, to inquire into this great source of national wealth. To that committee it appeared, that the best way of improving the fisheries was, to encourage the inhabitants living nearest to the seat of them to become fishers. And it being found that the north-western coast of the kingdom, though abounding with fish and fine harbours, was utterly destitute of towns, an act was passed for incorporating certain persons therein named, by the style of "The British society for extending of the fisheries, and improving the sea-coasts of this kingdom;" and to enable them to subscribe a joint stock, and therewith to purchase lands, and build thereon free towns, villages, and fishing-stations in the Highlands, and islands in that part of Great Britain called Scotland, and for other purposes. The isle of Mull, Loch-Broom, the Isles of Sky and of Canay, have already

been marked as proper situations for some of these towns. The progress of such an undertaking from its nature must be slow, but still slower when carried on with a limited capital arising from the subscriptions of a few public-spirited individuals. But it is not to be doubted that it will ultimately tend to the increase of the fisheries, and to the improvement of the Highland part of the kingdom. Its tendency is also to lessen the emigration of a brave and industrious race of inhabitants, many of whom have already removed with their families to America.

Anchovy Fishery. The anchovy is caught in the months of May, June, and July, on the coasts of Catalonia, Provence, &c. at which season it constantly repairs up the straits of Gibraltar into the Mediterranean. Collins says they are also found in plenty on the western coasts of England and Wales.

The fishing for them is chiefly in the night-time; when a light being put on the stern of their little fishing-vessels, the anchovies flock round, and are caught in the nets. But then it is asserted to have been found by experience, that anchovies taken thus by fire, are neither so good, so firm, nor so proper for keeping, as those which are taken without fire.

When the fishery is over, they cut off the heads, take out their gall and guts, and then lay them in barrels, and salt them. The common way of eating anchovies is with oil, vinegar, &c. in order to which they are first boned, and the tails, fins, &c. slipped off. Being put on the fire, they dissolve almost in any liquor. Or they are made into sauce by mincing them with pepper, &c. Some also pickel anchovies in small delft or earthen pots, made on purpose, of two or three pounds weight, more or less, which they cover with plaister to keep them the better. Anchovies should be chosen small, fresh pickled, white on the outside and red within. If genuine, they have round backs: for those which are flat or large are often nothing but sardines. Besides these qualities, the pickel, on opening the pots or barrels, should be of a good taste, and not have lost its flavour.

Cod-Fishery. There are two kinds of codfish; the one green or white cod; the other dried or cured cod; though it is all the same fish differently prepared; the former being sometimes salted and barrelled, then taken out for use; and the latter having laid for a competent time in salt, and then dried in the sun or smoke.

The chief fisheries for green cod are in the bay of Canada, on the great bank of Newfoundland, and on the isle of St. Peter, and the isle of Sable; to which places vessels resort from many parts both of Europe and America. They are from 100 to 150 tons burthen, and will catch between 30,000 and 40,000 cod each. The most essential part of the fishery is, to have a master who knows how to cut up the cod, one who is skilled to take off the head properly, and above all a good salter, on which the preserving of them, and consequently the success of the voyage, depend. The best season is from the beginning of February to the end of April; the fish, which in the winter retire to the deepest water, coming then on the banks, and fattening extremely. What are caught from March to June keep well; but those taken in July, August, and September, when it is warm on the banks, are apt to spoil soon. Each fisher takes but one at a time, yet the most expert will take from 350 to 400 in a day; but that is the most, the weight of the fish and the great coldness on the bank fatiguing very much. As soon as the cod are caught, the heads are taken off; they are opened, gutted, and salted; and the salter stows them in the bottom of the hold, head to tail, in beds a fathom or two square; putting layers of salt and fish alternately; but never mixing fish caught on different days. When they have lain thus three or four days to drain off the water, they are placed in another part of the ship, and salted again; where they remain till the vessel is loaded. Sometimes they are cut in thick pieces, and put in barrels for the greater convenience of carriage.

The principal fishery for dry cod is, from Cape Rose to the Bay des Exports, along the coast of Placentia, in which compass there are several commodious ports for the fish to be dried in. These, though of the same kind with the fresh cod, are much smaller, and therefore fitter to keep, as the salt penetrates more easily into them. The fishery of both is much alike; only this latter is most expensive, as it takes up more time, and employs more hands, and yet scarcely half so much salt is spent in this as in the other. The bait is herring, of which great quantities are taken on the coast of Placentia. When several vessels meet and intend to fish in the same port, he whose shallop first touched ground, becomes entitled to the quality and privileges of admiral: he has the choice of his station, and the refusal of all the wood on the coast at his arrival. As fast as the masters arrive, they unrig all their vessels, leaving nothing but the shrouds to sustain the masts; and in the mean time the mates provide a tent on shore covered with branches of trees, with sails over them, with a scaffold of great trunks of pines, 12, 15, 16, and often 20 feet high, commonly from 40 to 60 feet long, and about one-third as much in breadth. While the scaffold is preparing, the crew are fishing; and as fast as they catch, they bring their fish ashore, and open and salt them upon moveable benches; but the main salting is performed on the scaffold. When the fish have taken salt, they wash and hang them to drain on rails; when drained, they are laid on a sort of stages, which are small pieces of wood laid across, and covered with branches of trees, having the leaves stripped off for the passage of the air. On these stages they are disposed, a fish thick, head against tail, with the back uppermost, and are turned carefully every 24 hours. When they begin to dry, they are laid in heaps 10 or 12 thick, in order to retain their warmth; and every day the heaps are enlarged, till they become double their first bulk; then two heaps are joined together, which they turn every day as before; lastly, they are salted again, beginning with those first salted; and being laid in huge piles, they remain in that situation till they are carried on board the ships, where they are laid on the branches of trees disposed for that purpose, upon the ballast, and round the ship, with mats to prevent their contracting any moisture.

The cod supplies four kinds of commodities, viz. the sounds, the tongues, the roes, and the oil, which is extracted from its liver. The first are salted at the fishery, together with the fish, and put in barrels of from 600 to 700 pounds. The tongue are cured in like manner, and brought in barrels of from 400 to 500 pounds. The roes

are also salted in barrels, and serve to cast into the sea to draw fishes together, and particularly pilchards. The oil comes in barrels of from 400 to 520 pounds and is used in dressing leather. In Scotland, they catch a small kind of cod on the coasts of Buchan, and all along the Murray Frith on both sides; as also in the Frith of Forth, Clyde, &c. which is much esteemed. They salt and dry them in the sun upon rocks, and sometimes in the chimney.

Herring-Fishery. The great stations for the fishery are off the Shetland and Western isles, and off the coast of Norfolk, in which the Dutch also share. See the article CLUPEA. There are two seasons for herring-fishing: the first from June to the end of August; and the second in autumn, when the fogs become very favourable for this kind of fishing. The Dutch begin their herring-fishing on the 24th of June, and employ a vast number of vessels called busses, between 54 and 60 tons burden each, and carrying three or four small guns. They never stir out of port without a convoy, unless there are enough together to make about 18 or 20 cannon among them, in which case they are allowed to go in company. Before they go out, they make a verbal agreement, which has the same force as if it was in writing. The regulations of the admiralty of Holland have been partly followed by the French and other nations, and partly improved and augmented with new ones; as, that no fisher shall cast his net within 100 fathoms of another boat: that while the nets are cast, a light shall be kept on the hind part of the vessel: that when a boat is by any accident obliged to leave off fishing, the light shall be cast into the sea: that when the greater part of a fleet leaves off fishing, and casts anchor, the rest shall do the same, &c.

In the late king's reign, very vigorous efforts were made, and bounties allowed, for the encouragement of the British herring-fisheries: the first was, of 30*s.* per ton to every buss of 70 tons and upwards. This bounty was afterwards raised to 50*s.* per ton, to be paid to such adventurers as were entitled to it by claiming it at the place of rendezvous. The busses are from 20 to 90 tons burden, but the best size is 80. A vessel of 80 tons ought to take ten lasts, or 120 barrels of herrings, to clear expenses, the price of the fish to be admitted to be a guinea a barrel. A ship of this size out to have 18 men, and three boats; one of 20 tons should have six men, and every five tons above require an additional hand. To every ton are 250 yards of net; so a vessel of 80 tons carries 20,000 square yards; each net is 12 yards long, and 10 deep; and every boat takes out from 20 to 30 nets, and puts them together, so as to form a long train; they are sunk at each end of the train by a stone, which weighs it down to the full extent: the top is supported by buoys made of sheep-skin, with a hollow stick at the mouth, fastened tight; through this the skin is blown up, and then stopped with a peg, to prevent the escape of the air. Sometimes these buoys are placed at the top of the nets; at other times the nets are suffered to sink deeper, by lengthening the cords fastened to them, every cord being for that purpose 10 or 12 fathoms long. But the best fisheries are generally in more shallow water.

Of the Scots fishery in the Western Isles, the following account is given by Mr. Pennant: "The fishing is always performed in the night, unless by accident. The busses remain at anchor, and send out their boats a little before sunset; which continue out, in winter and summer, till daylight; often taking up and emptying their nets, which they do 10 or 12 times in a night, in case of good success. During winter it is a most dangerous and fatiguing employ, by reason of the greatness and frequency of the gales in these seas, and in such gales are the most successful captures; but by the providence of Heaven, the fishers are seldom lost, and what is wonderful, few are visited with illness. They go out well prepared, with a warm great coat, boots, and skin aprons, and a good provision of beef and spirits. The same good fortune attends the busses, which in the tempestuous season, and in the darkest nights, are continually shifting in these narrow seas from harbour to harbour. Sometimes 80 barrels of herrings are taken in a night by the boats of a single vessel. It once happened, in Loch-Slappan in Skie, that a buss of 80 tons might have taken 200 barrels in one night, with 10,000 square yards of net; but the master was abliged to desist, for want of a sufficient number of hands to preserve the capture. The herrings are preserved by salting after the entrails are taken out. The last is an operation performed by the country people, who get three-halfpence per barrel for their trouble, and sometimes even in the winter, can gain fifteenpence a day. This employs both women and children; but the salting is only entrusted to the crew of the busses. The fish are laid on their backs in the barrels, and layers of salt between them. The entrails are not lost, for they are boiled into an oil; 8000 fish will yield ten gallons, valued at one shilling the gallon. A vessel of 80 tons take out 244 barrels of salt; a drawback is allowed for each barrel used by the foreign or Irish exportation of the fish; but there is a duty per barrel for the home-consumption, and the same for those sent to Ireland. The barrels are made of oak staves, chiefly from Virginia; the hoops from several parts of England, and are either of oak, birch, hazel, or willow; the last from Holland, liable to a duty. The barrels cost about 3*s.* each; they hold from 500 to 800 fish, according to the size of the fish; and are made to contain 32 gallons. The barrels are inspected by proper officers: a cooper examines if they are statutable and good; if faulty he destroys them, and obliges the maker to stand to the loss."

Herrings are cured either white, (*i. e.* pickled) or red. Of the first, those done by the Dutch are the most esteemed, being distinguished into four sorts, according to their sizes; and the best are those that are fat, fleshy, firm, and white, salted the same day they are taken with good salt and well barrelled. The British-cured herrings are little inferior if not equal to the Dutch; for, in spite of all their endeavours to conceal the secret, their method of curing, lasting, or casking the herrings, has been discovered, and is as follows. After they have hauled in their nets, which they drag in the stern of their vessels backwards and forwards in traversing the coast, they throw them upon the ship's deck, which is cleared of every thing for that purpose: the crew is separated into divisions, and each division has a peculiar task; one part opens and guts the herrings, leaving the melts and roes; another cures and salts them, by lining or rubbing their inside with salt; the next packs them, and between each row and division they sprinkle hand-

fuls of salt; lastly, the cooper puts the finishing hand to all, by heading the casks very tight and stowing them in the hold. Red-herrings must lie 24 hours in the brine, inasmuch as they are to take all their salt there; and when they are taken out, they are spitted, that is, strung by the head on little wooden spits, and then hung in a chimney made for that purpose. After which, a fire of brush wood, which yields much smoke but no flame, being made under them, they remain there till sufficiently smoked and dried, and are afterwards barrelled up for keeping.

Lobster-Fishery. Lobsters are taken along the British channel, and on the coast of Norway, whence they are brought to London for sale; and also in the frith of Edinburgh, and on the coast of Northumberland. See the article CANCER. By 10 and 11 W. III. c. 24. no lobster is to be taken under eight inches in length, from the peak of the nose to the end of the middle fin of the tail; and by 9 G. II. cap. 33. no lobsters are to be taken on the coast of Scotland from the first of June to the first of September.

Mackrel-Fishery. The mackrel is a summer fish of passage, found in large shoals, in different parts of the ocean, not far north; but especially on the French and English coasts. The fishing is usually in the months of April, May, and June, and even July, according to the place. See SCOMBER. They enter the English Channel in April, and proceed up to the straits of Dover as the summer advances; so that by June they are on the coasts of Cornwall, Sussex, Normandy, Picardy, &c. where the fish is most considerable. They are an excellent food fresh; and not to be despised when well prepared, pickled, and put up in barrels; a method of preserving them chiefly used in Cornwall. The fish is taken in two ways; either with a line or nets: the latter is the more considerable, and is usually performed in the night-time. The rules observed in the fishing for mackrel are much the same as those already mentioned in the fishery of herrings.

There are two ways of pickling them: the first is, by opening and gutting them, and filling the belly with salt, crammed in as hard as possible with a stick; which done they range them in strata or rows, at the bottom of the vessel, strewing salt between the layers. In the second way, they put them immediately into tubs full of brine, made of fresh water and salt, and leave them to steep, till they have imbibed salt enough to make them keep; after which they are taken out, and barrelled up, taking care to press them close down. Mackrel are not cured or exported as merchandize, except a few by the Yarmouth and Leostoff merchants, but are generally consumed at home; especially in the city of London, and the sea-ports between the Thames and Yarmouth east, and the Land's-end of Cornwall west.

Oyster-Fishery. This fishery is principally carried on at Colchester in Essex; Feversham and Milton in Kent; the Isle of Wight; the Swales of the Medway; and Tenby on the coast of Wales. From Feversham, and the adjacent parts, the Dutch have sometimes loaded a hundred large hoys with oysters in a year. They are also taken in large quantities near Portsmouth, and in all the creeks and rivers between Southampton and Chichester: many of which are carried about by sea to London and to Colchester, to be fed in the pits about Wavenhoe and other places. See OSTREA.

Pilchard-Fishery. The chief pilchard-fisheries are along the coasts of Dalmatia, on the coast of Bretagne, and along the coast of Cornwall and Devonshire. That of Dalmatia is very plentiful: that on the coasts of Bretagne employs annually about 300 ships. Of the pilchard-fishery on the coast of Cornwall, the following account is given by Dr. Borlase: "It employs a great number of men on the sea, training them to naval affairs; employs men, women, and children at land, in salting, pressing, washing, and cleaning; in making boats, nets, ropes, casks, and all the trades depending on their construction and sale. The poor are fed with the offals of the captures, the land with the refuse of the fish and salt; the merchant finds the gains of commission and honest commerce, the fisherman the gains of the fish. Ships are often freighted hither with salt, and into foreign countries with fish, carrying off at the same time part of our tin. Of the usual produce of the great number of hogsheads exported each year for ten years from 1747 to 1756 inclusive, from the four ports of Fowey, Falmouth, Penzance, and St. Ives, it appears that Fowey has exported yearly 1732 hogsheads; Falmouth 14,631 hogsheads and two-thirds; Penzance and Mount's-bay 12,149 hogsheads and one-third; St. Ives 1282 hogsheads; in all amounting to 29,795 hogsheads. Every hogshead for ten years last past, together with the bounty allowed for each hogshead exported, and the oil made out of each hogshead, has amounted one year with another at an average, to the price of 1*l*. 13*s*. 3*d*.: so that the cash paid for pilchards exported has, at a medium, annually amounted to the sum of 49,532*l*. 10*s*." The numbers that are taken at one shooting out of the nets are amazingly great. Mr. Pennant says, that Dr. Borlase assured him, that on the 5th of October 1767, there were at one time inclosed in St. Ives's bay 7000 hogsheads, each hogshead containing 35,000 fish, in all 245 millions.

The pilchards naturally follow the light, which contributes much to the facility of the fishery: the season is from June to September. On the coasts of France they make use of the roes of the cod-fish as a bait; which, thrown into the sea, makes them rise from the bottom, and run into the nets. On the English coasts there are persons posted ashore, who, spying by the colour of the water where the shoals are, make signs to the boats to go among them to cast their nets. When taken, they are brought on shore to a warehouse, where they are laid up in broad piles, supported with backs and sides; and as they are piled, they salt them with bay-salt; in which lying to soak for 30 or 40 days, they run out much blood, with dirty pickel and bittern: then they wash them clean in sea-water; and when dry, barrel and press them hard down to squeeze out the oil, which issues out at a hole in the bottom of the cask.

Salmon-Fishery. The chief salmon-fisheries in Europe are in England, Scotland, and Ireland, in the rivers and sea-coasts adjoining to the river-months. The most distinguished for salmon in Scotland are, the river Tweed, the Clyde, the Tay, the Dee, the Don, the Spey, the Ness, the Bewly, &c. in most of which it is very common, about the height of summer, especially if the weather happens to be very hot, to catch four or five

score of salmon at a draught. The chief rivers in England for salmon are, the Tyne, the Trent, the Severn, and the Thames. The fishing is performed with nets, and sometimes with a kind of locks or weirs made on purpose, which in certain places have iron or wooden grates so disposed, in an angle, that being impelled by any force in a contrary direction to the course of the river, they may give way and open a little at the point of contact, and immediately shut again, closing the angle. The salmon, therefore, coming up into the rivers, are admitted into these grates, which open, and suffer them to pass through, but shut again and prevent their return. The salmon is also caught with a spear, which they dart into him when they see him swimming near the surface of the water. It is customary likewise to catch them with a candle and lanthorn, or wisp of straw set on fire; for the fish naturally following the light, are struck with the spear, or taken in a net spread for that purpose, and lifted with a sudden jerk from the bottom.

"The capture of salmon in the Tweed, about the month of July, (says Mr. Pennant) is prodigious. In a good fishery, often a boat-load, and sometimes near two, are taken in a tide: some few years ago there were above 700 fish taken at one haul, but from 50 to 100 is very frequent. The coopers in Berwick then begin to salt the salmon thoroughly in pipes and other large vessels, and afterwards barrel them to send abroad, having then far more than the London markets can take off their hands.

"Most of the salmon taken before April, or to the setting in of the warm weather, is sent fresh to London in baskets; unless now and then the vessel is disappointed by contrary winds of sailing immediately; in which case the fish is brought ashore again to the coopers' offices, and boiled, pickled, and kitted, and sent to the London markets by the same ship, and fresh salmon put in the baskets in lieu of the stale ones. At the beginning of the season, when a ship is on the point of sailing, a fresh clean salmon will sell from a shilling to eighteen pence a pound; and most of the time that this part of the trade is carried on, the prices are from five to nine shillings per stone; the value rising and falling according to the plenty of fish, or the prospect of a fair or foul wind. Some fish are sent in this manner to London the latter end of September, when the weather grows cool; but then the fish are full of large roes, grow very thin-bellied, and are not esteemed so palatable.

"The season for fishing in the Tweed begins November 30th, but the fishermen work very little till after Christmas: it ends on Michaelmas-day; yet the corporation of Berwick (who are conservators of the river) indulge the fishermen with a fortnight past that time, on account of the change of the style.

"There are on the river 41 considerable fisheries, extending upwards, about 14 miles from the mouth (the others above being of no great value), which are rented for near 5400*l*. per annum: the expense attending the servants' wages, nets, boats, &c. amounts to 5000*l*, more; which together makes up the sum 10,400*l*. Now, in consequence, the produce must defray all, and no less than 20 times that sum of fish will effect it; so that 208,000 salmon must be caught there, one year with another.

"Scotland possesses great numbers of fine fisheries on both sides of that kingdom. The Scotch in early times had most severe laws against the killing of this fish: for the third offence was made capital, by a law of James IV. Before that, the offender had power to redeem his life. They were thought in the time of Henry VI. a present worthy of a crowned head; for in that reign the queen of Scotland sent to the duchess of Clarence 10 casks of salted salmon, which Henry directed to pass duty-free. The salmon are cured in the same manner as at Berwick, and a great quantity is sent to London in the spring; but after that time, the adventurers begin to barrel and export them to foreign countries; but we believe that commerce is far less lucrative than it was in former times, partly owing to the great increase of the Newfoundland fishery, and partly to the general relaxation of the discipline of abstinence in the Romish church.

"Ireland (particularly the north) abounds with this fish; the most considerable fishery is at Cranna, on the river Ban, about a mile and a half from Coleraine. When I made the tour of that hospitable kingdom in 1754, it was rented by a neighbouring gentleman for 620*l*. a year; who assured me, that the tenant, his predecessor, gave 1600*l*. per annum, and was a much greater gainer by the bargain, for the reasons before-mentioned, and on account of the number of poachers who destroy the fish in the fence-months.

"The mouth of this river faces the north; and is finely situated to receive the fish that roam along the coast in search of an inlet into some fresh water, as they do all along that end of the kingdom which opposes itself to the northern ocean. We have seen near Ballicastle, nets placed in the sea at the foot of the promontories that jut into it, which the salmon strike into as they are wandering close to shore; and numbers are taken by that method.

"In the Ban they fish with nets 18 score yards long, and are continually drawing night and day the whole season, which we think lasts about four months, two sets of 16 men each alternately relieving one another. The best drawing is when the tide is coming in; we were told, that in a single draught there were once 840 fish taken.

"A few miles higher up the river is a weir, where a considerable number of fish that escape the nets are taken. We were lately informed, that in the year 1760, about 320 tons were taken in the Cranna fishery."

With regard to the manner of curing salmon when the fish are taken, they are opened along the back, the guts and gills, and the greatest part of the bones removed, so as to make the inside as smooth as possible. They then salt the fish in large tubs for the purpose, where they lie a considerable time soaking in brine; and about October, they pack them close up in barrels, and send them to London or up the Mediterranean. They have also in Scotland a great deal of salmon salted in the common way, which after soaking in brine a competent time is well pressed, and then dried in smoke: this is called kipper, and is chiefly made for home consumption; and if properly cured and prepared, is reckoned very delicious.

Sturgeon-Fishery. See Accipenser. The greatest sturgeon-fishery is in the mouth of the Volga, on the Caspian sea; where the Muscovites employ a great num-

ber of hands, and catch them in a kind of inclosure formed by huge stakes representing the letter Z repeated several times. These fisheries are open on the side next the sea, and close on the other, by which means the fish ascending in its season up the river, is embarrassed in these narrow angular retreats, and is easily killed with a harping-iron. Sturgeons, when fresh, eat deliciously; and in order to make them keep, they are salted or pickled in large pieces, and put in kegs of from 30 to 50 pounds. But the great object of this fishery is the roe, of which the Muscovites are extremely fond, and of which is made the cavear, or kavia, so much esteemed by the Italians. See Cavear.

Tunny-Fishery. The tunny (a species of Scomber, which see) was a fish well known to the ancients, and made a great article of commerce: and there are still very considerable tunny-fisheries on the coasts of Sicily, as well as several other parts of the Mediterranean. The nets are spread over a large space of sea by means of cables fastened to anchors, and are divided into several compartments. The entrance is always directed, according to the season, towards that part of the sea from which the fish are known to come. A man placed upon the summit of a rock high above the water, gives the signal of the fish being arrived; for he can discern from that elevation what passes under the waters infinitely better than any person nearer the surface. As soon as notice is given that the shoal of fish has penetrated as far as the inner compartment, or the chamber of death, the passage is drawn close, and the slaughter begins. The undertakers of these fisheries pay an acknowledgment to the king, or the lord upon whose land they fix the main stay or foot of the tonnara; they make the best bargain they can; and till success has crowned their endeavours, obtain this leave for a small consideration; but the rent is afterwards raised in proportion to their capture.

The tunny enters the Mediterranean about the vernal equinox, travelling in a triangular phalanx, so as to cut the waters with its point, and to present an extensive base for the tides and currents to act against and impel forwards. These fish repair to the warm seas of Greece to spawn, steering their course thither along the European shores, but as they return, approach the African coast; the young fry is placed in the van of the squadron as they travel. They come back from the east in May, and abound on the coast of Sicily and Calabria about that time. In autumn they steer northward, and frequent the neighbourhood of Amalfi and Naples; but during the whole season stragglers are occasionally caught. When taken in May, the usual time of their appearance in the Calabrian bays, they are full of spawn, and their flesh is then esteemed unwholesome, apt to occasion head achs and flatulency; the milts and roes are particularly so at that season. To prevent these bad effects, the natives fry them in oil, and afterwards salt them. The quantity of this fish consumed annually in the two Sicilies almost exceeds the bounds of calculation. From the beginning of May to the end of October it is eaten fresh, and all the rest of the year it is in use salted. The most delicate part is the muzzle. The belly salted was called tarantallum, and accounted a great delicacy by the Romans; its present name is surra. The rest of the body is cut into slices, and put into tubs.

Turbot-Fishery. Turbots grow to a large size, viz. from 23 to 30 pounds. They are taken chiefly off the north coast of England, and others off the Dutch coast. The large turbot (as well as several other kinds of flat fish) are taken by the hook and line, for they lie in deep water; the method of taking them in weirs or staked nets being very precarious. When the fishermen go out to sea, each person is provided with three lines, which are coiled on a flat oblong piece of wicker-work; the hooks being baited, and placed regularly in the centre of the coil. Each line is furnished with 14 score of hooks, at the distance of six feet two inches from each other. The hooks are fastened to the lines upon sneads of twisted horsehair 27 inches in length. When fishing, there are always three men in each coble, and consequently nine of these lines are fastened together, and used as one line, extending in length near three miles, and furnished with 2550 hooks. An anchor and a buoy are fixed at the first end of the line, and one more of each at the end of each man's lines; in all four anchors, which are commonly perforated stones, and four buoys made of leather or cork. The line is always laid across the current. The tides of flood and ebb continue an equal time upon the coast, and, when undisturbed by winds, run each way about six hours; they are so rapid that the fishermen can only shoot and haul their lines at the turn of the tide, and therefore the lines always remain upon the ground about six hours; during which the myxine glutinosa of Linnæus will frequently penetrate the fish that are on the hooks, and entirely devour them, leaving only the skin and bones. The same rapidity of tides prevents their using hand-lines; and therefore two of the people commonly wrap themselves in the sail, and sleep, while the other keeps a strict look-out, for fear of being run down by ships, and to observe the weather. For storms often rise so suddenly, that it is with extreme difficulty they can sometimes escape to the shore, leaving their lines behind.

Besides the coble, the fishermen have also a five-men boat, which is forty feet long and 15 broad, and 25 tons burden; it is so called, though navigated by six men and a boy, because one of the men is commonly hired to cook, &c. and does not share in the profits with the other five. This boat is decked at each end, but open in the middle, and has two large lug-sails. All the able fishermen go in these boats to the herring-fishery at Yarmouth in the end of September, and return about the middle of November. The boats are then laid up till the beginning of Lent, at which time they go off in them to the edge of the Dogger, and other places, to fish for turbot, cod, ling, skates, &c. They always take two cobles on board; and when they come upon their ground, anchor the boat, throw out the cobles, and fish in the same manner as those do who go from the shore in a coble; with this difference only, that here each man is provided with double the quantity of lines, and instead of waiting the return of the tide in the coble, they return to their boat and bait their other lines; thus hawling one set and shooting another every turn of the tide. They commonly run into harbour twice a week to deliver their fish.

The best bait is fresh herring cut in pieces of a proper size: the five-men boats are always furnished with nets for taking them. Next to herrings are the lesser lampreys. The next baits in esteem are small haddocks cut

in pieces, sand worms, and limpets, here called flidders; and when none of these can be had, they use bullock's liver. The hooks are two inches and a half long in the shank, and near an inch wide between the shank and the point. The line is made of small cording, and is always tanned before it is used. Turbots are extremely delicate in their choice of baits; for if a piece of herring or haddock has been twelve hours out of the sea, and then used as bait, they will not touch it.

FISHERY, *Whale*. For the natural history of the whale, the importance of the whale fishery to Britain, and other particulars, see the article BALÆNA.

We shall here only remark, that the legislature, justly considering that trade as of great national importance, bestowed on it at different periods very considerable encouragement. In particular, every British vessel of 200 tons or upwards, bound to the Greenland seas on the whale-fishery, if found to be duly qualified according to the act, obtained a licence from the commissioners of the customs to proceed on such voyage; and on the ship's return, the master and mate making oath that they proceeded on such voyage and no other, and used all their endeavours to take whales, &c. and that all the whale-fins, blubber, oil, &c. imported in their ship, were taken by their crew in those seas, there was allowed 40*s*. for every ton, according to the admeasurement of the ship.

It was afterwards found, however, that so great a bounty was neither necessary to the success of the trade, nor expedient with regard to the public. In 1786, therefore, the acts conferring the said emoluments being upon the point of expiring, the subject was brought under the consideration of parliament; and it was proposed to continue the former measures, but with a reduction of the bounty from 40*s*. to 30*s*. In proposing this alteration, it was stated, "that the sums which this country had paid in bounties for the Greenland fishery amounted to 1,265,461*l*.; that in the last year we had paid 94,858*l*.; and that, from the consequent reduction of the price of the fish, the public at present paid 60 per cent. upon every cargo. In the Greenland fishery there were employed 6000 seamen, and these seamen cost government 13*l*. 10*s*. per man per annum, though we were never able to obtain more than 500 of that number to serve on board our ships of war. Besides, the vast encouragement given to the trade had occasioned such a glut in the market, that it was found necessary to export considerable quantities; and thus we paid a large share of the purchase-money for foreign nations, as well as for our own people, besides supplying them with the materials of several important manufactures." This proposition was opposed by several members, but was finally carried; and the propriety of the measure became very soon apparent. At that time (1786) the number of ships employed from England in the whale-fishery to Davis's Straights and the Greenland seas amounted to 139, besides 15 from Scotland. The proposed alteration took place the next year (1787); and notwithstanding the diminution of the bounty, the trade increased; the number of ships employed the same year from England amounting to 217, and the next year (1788) to 222.

The whale-fishery has of late years been considerably indebted to the introduction of a new kind of harpoon, called the gun-harpoon, which the Society for the Encouragement of Arts have exerted themselves to bring into general use.

FISHING, in general, the art of catching fish, whether by means of nets or spears, or of the line and hook. That which is performed by the net, spear, or harpoon, for fish that go in shoals, has been explained in the preceding articles. That performed by the rod, line, and hook, is usually termed angling; see that article: and for the particular manner of angling for the different kinds of fish, see their respective names. The following, however, require to be mentioned here.

1. The barbel, so called on account of the barb or beard that is under his chaps (see CYPRINUS), though a coarse fish, gives considerable exercise to the angler's ingenuity. They swim together in great shoals, and are at their worst in April, at which time they spawn, but soon come in season: the places whither they chiefly resort, are such as are weedy and gravelly rising grounds, in which this fish is said to dig and root with his nose like a swine. In the summer he frequents the strongest and swiftest currents of waters; as deep bridges, weirs, &c. and is apt to settle himself amongst the piles, hollow places, and moss weeds, and will remain there immoveable: but in winter he retires into deep waters, and helps the female to make a hole in the sands to hide her spawn in, to hinder its being devoured by other fish. He is a very curious and cunning fish; for if his baits are not sweet, clean, well scoured, and kept in sweet moss, he will not bite; but if those are well-ordered and carefully kept, he will bite with great eagerness. The best bait for him is the spawn of a salmon, trout or any other fish; or a piece of chandler's greaves which has been boiled and washed; he will also take a large lob-worm; and if you would have good sport with him, bait the places where you intend to fish with it a night or two before with tallow-chandler's greaves; and the earlier in the morning, or the later in the evening, that you fish, the better it will be. Your rod and line must be both strong and long, with a running plummet on the line; and let a little bit of lead be placed a foot or more above the hook, to keep the bullet from falling on it: so the bait will be at the bottom, where they always bite; and when the fish takes the bait, your plummet will lie and not choke him. By the bending of your rod you may know when he bites, as also with your hand you will feel him make a strong snatch; then strike, and you will rarely fail, if you play him well; but if you manage him not dexterously he will break your line. The best time for fishing is about nine in the morning, and the most proper season is the latter part of May, June, July, and the beginning of August.

2. The bleak is an eager fish, caught with all sorts of worms bred on trees or plants; as also with flies, paste, sheep's blood, &c. Bleak may be angled for with half a score of hooks at once, if they can be all fastened on: he will also in the evening take a natural or artificial fly. If the day is warm and clear, there is no fly so good for him as the small fly at the top of the water, which he will take at any time of the day, especially in the evening. But if the day is cold and cloudy, gentles and caddis are the best; about two feet under water. But the best method is with a drabble, thus: tie 8 or 10 small hooks across a line, two inches above one another; the biggest hook the lowermost, (whereby you may some-

times take a better fish) and bait them with gentles, flies, or some small red worms, by which means you may take half a dozen or more at a time; but when you have them they are not worth the catching, except as a bait for pike, trout, &c.

3. For the bream observe the following directions, which will also apply to carp, tench, or perch fishing. Procure about a quart of large red worms: put them into fresh moss well washed and dried every three or four days, feeding them with fat mould and chopped fennel, and they will be thoroughly scoured in about three weeks.

Let your lines be silk, and silkworm-gut at bottom; let the floats be either swan quills or goose-quills. Let your plumb be a piece of lead in the shape of a spear, with a small ring at the point of it; fasten the lead to the line, and the line-hook to the lead; about ten or twelve inches space between lead and hook will be enough; and take care the lead be heavy enough to sink the float. Having baited your hook well with a strong worm, the worm will draw the hook up and down in the bottom, which will provoke the bream to bite the more eagerly. It will be best to fit up three or four rods and lines in this manner, and set them as will be directed, and this will afford you much the better sport. Find the exact depth of the water if possible, that your float may swim on its surface directly over the lead; then provide the following ground-bait. Take about a peck of sweet gross-ground-malt, and having boiled it a very little, strain it hard through a bag, and carry it to the water-side, where you have sounded; and into the place where you suppose the fish resort, there throw in the malt by handfuls squeezed hard together, or rather mixed with a little clay, that the stream may not separate it before it comes to the bottom; and be sure to throw it in at least a yard above the place where you intend the hook shall lie, otherwise the stream will carry it down too far. Do this about nine o'clock at night, keeping some of the malt in the bag, and go to the place about three the next morning, but approach very warily, lest you should be seen by any of the fish; for it is said that they have their sentinels watching on the top of the water, while the rest are feeding below. Having baited your hook so that the worm may crawl to and fro, the better to allure the fish to bite, cast it in at the place where you find the fish to stay most, which is generally in the broadest and deepest part of the river, so that it may rest about the middle of your ground-bait. Cast in your second line so that it may rest a yard above that, and a third about a yard below it. Let your rods lie on the bank with some stones to keep them down at the great ends; and then withdraw yourself, yet not so far but that you can have your eye upon all the floats: and when you see one bitten and carried away, do not be too hasty to run in, but give time to the fish to tire himself, and then touch him gently. When you perceive the float sink, creep to the water-side, and give it as much line as you can. If it is a bream or carp, he will run to the other side. Strike him gently, and hold your rod at a bend a little while, but do not pull, for then you will spoil all; but you must tire them before they can be landed, for they are very shy. If there are any carp in the river, it is an even chance that you take one or more of them; but if there are any pike or perch, they will be sure to visit the ground-bait, though they will not touch it, being drawn together by the great resort of the small fish, and until you remove them, it is in vain to think of taking the bream or carp. In this case, bait one of your hooks with a small bleak, roach, or gudgeon, about two feet deep from your float, with a little red worm at the point of your hook, and if a pike is there he will be sure to snap at it. This sport is good till nine o'clock in the morning, and in a gloomy day till night; but do not frequent the place too much, lest the fish grow shy.

4. The carp. A person who angles for carp, must arm himself with abundance of patience, because of their extraordinary subtilty and shyness: they always choose to lie in the deepest places either of ponds or rivers, where there is but a small running stream. Further, observe, that they will seldom bite in cold weather; and you cannot be too early or too late at the sport in hot weather; yet if he bites you need not fear his hold, for he is one of those leather-mouthed fish that have their teeth in the throat. Neither must you forget, in angling for him, to have a strong rod and line; and since he is so very wary, it will be proper to entice him, by baiting the ground with a coarse paste.

He seldom refuses the red worm in March, the caddis in June, or the grasshopper in July, August, and September. This fish, however, does not only delight in worms, but also in sweet paste, of which there is great variety; the best is made of honey and sugar mixed up with flour, some veal minced fine, and a little cotton, or white wool to make it adhere to the hook. Some of it ought to be thrown into the water a few hours before you begin to angle; neither will small pellets thrown into the water two or three days before be worse for this purpose, especially if chickens' guts, garbage, or blood mixed with bran and cow-dung, are also thrown in. If you fish with gentles, anoint them with honey. Honey and crumbs of wheat-bread, mixed together, make also a very good paste; or pellets of wheat-bread alone will answer very well.

In taking a carp either in a pond or river, if the angler intends to add profit to his pleasure, he must take a peck of ale-grains, and a good quantity of any blood to mix with the grains; baiting the ground with it where he intends to angle. This food will wonderfully attract the scale-fish, as carp, tench, roach, dace, and bream. Let him angle in a morning, plumbing his ground, and angling for carp with a strong line: the bait must be either paste or a knotted red worm; and by this means he will have sport enough.

5. The pike is caught either by a live bait, which is cruel, or by a trowl, which is a dead or artificial fish, frog, or mouse, fastened to a double hook with some lead to sink it, and gently played by the hand of the angler so as to imitate life. There are two ways of trowling, at snap or at gorge; at snap, the angler strikes the moment the fish springs at the bait; at gorge he suffers him to carry it to his hole, giving it out line as may be required, and swallow it, and strikes him in about ten minutes.

6. Salmon and trout fishing are nearly alike. The trout is caught with a worm, a minnow, or a fly; but the

only elegant sport of this kind is that with the artificial fly, which will be afterwards described.

7. The gudgeon is a small fish, of very delicious taste. It spawns three or four times in the summer season, and feeds in streams, slighting all kinds of flies, but is easily taken with a small red worm, fishing near the ground; and being a leather-mouthed fish, will not easily get off the hook when struck. The gudgeon may be either fished with a float, the hook being on the ground, or by hand, with a running line on the ground without cork or float. He will bite well at wasps, gentles, and cadworms; and a person may fish with two or three hooks at the same time. Before you angle for gudgeons, stir up the sand or gravel with a long pole, which will make them gather to the place, and bite the faster.

8. The tench is a fine fresh-water fish, having very small scales, but large smooth fins, with a red circle about the eyes, and a little barb hanging at each corner of the mouth. It takes more delight among weeds in ponds than in clear rivers, and loves to feed in foul water. His slime is said to have a healing quality for wounded fish, upon which he is called the fishes' physician. When carp, pike, &c. are hurt, it is said they find relief by rubbing themselves against the tench. The season for catching this fish is June, July, and August, very early and late, or even all night, in the still part of the rivers. The bait is a large red worm, at which he bites eagerly, especially if dipped in tar. He delights in all sorts of paste made of strong-scented oils, or tar, or a paste of brown-bread and honey; nor does he refuse the cadworm, lobworm, flagworm, green gentles, cod bait, or soft boiled bread-grain.

9. Smelts are caught at high-tide during the summer and autumn months, with a hook and line, about Limehouse and Poplar. They fish with about ten hooks on the same line, at different depths, each baited with a small piece of smelt, and sometimes two or three are caught at once.

An Epitome of the whole Art of Fishing, wherein are shown at one view, the Harbours, Seasons, and Depths, for catching all sorts of Fish usually angled for; also the various Baits for each, so digested as to contain the Essence of all the Treatises ever written on the subject, exempt from the superfluities, which tend more to perplex than instruct.

Names.	Where found.	Season.	me to angle.	Depth from ground.	Proper Baits. Flies. No.	Pastes No.	Worms. No.	Fish and Insects. No. 8
Bream	rough str. river or mid. pond	April to Mich.	sun-rise to 9 3 to sun-set	touch ground	——	1 3	1 to 7	No. 8
Barbel	gravel-banks in currents under bridges	April to Aug	very early or late	ditto	——	2	2 6 7	——
Bleak	sandy bottom, deep rivers, ships' sterns	May to Oct.	all day	6 inches from bottom	1 2	2	2 3 8	——
Carp	still deep mud bottom, pond or river	May to Aug.	sun-rise to 9 3 to sun-set	3 inches from bottom hot weather, mid-water	——	1 3 4	1 2 3 4 7	——
Chub or Chevin	ditto	May to Dec.	ditto	ditto	1 to 5	2	1 2 4 5	7 8
Dace	sandy bottom, deep rivers, ships' sterns	May to Oct.	all day	6 to 12 inches from bottom	ditto	3 4	1 to 5 & 8	——
Gudgeon	gravel shoals	May to Oct.	ditto	near, or on ground	——	ditto	2 8	——
Pike	near clay-banks	all the year	ditto	mid-water	wh. stro. and snap	line float hook fixt	—— on shore	1 2 3 4 5 6 7
Perch	river in stream / pond deepest part — gravel or weedy bottom	May to Aug. / Aug. to May.	S.-rise to 10 2 to sun-set / mid-day	ditto / 6 inches from bottom	2	1	3 5 7 8	1 6
Pope	deep holes in rivers	May to Oct.	all day	ditto	5	——	all	——
Roach	sandy bottom, deep rivers, ships' sterns	May to Oct.	ditto	6 to 12 inches	1 2 4 5	3 4	ditto	8
Salmon	deep rivers	Mar. to Sept.	8 to 9, 3 to 6	mid-way to the bottom	all large	——	1 5 6 7	1
Smelts	ships' sterns and docks	Apr. to Oct.	all day	mid-way to the bottom variable	all small	——	1 2 5	bits of smelts
Trout	purling stream, and eddies of stony-bottom river	Mar. to Mich.	ditto	cold weather, 6 inches to 9 hot weath. top to mid-wat.	1 to 5	——	1 2 5 to 8	1 8
Tench	mud-bottom, river or pond	all the year	sun-rise to 9 3 to sun-set	cold wea. 3 inch. from bot. hot weather, mid-water	——	1 3 4	1 3 4 to 7	——
Umber or Grayling	clay-bottom, swift stream	all the year	all day	cold weather, 6 to 9 inch hot weath. top to mid-wat	1 to 5	——	all	1 8

Description of proper baits for the several sorts of fish referred to in the foregoing table.—Flies. 1. Stone-fly, found under hollow stones at the side of rivers, is of a brown colour, with yellow streaks on the back and belly, has large wings, and is in season from April to July. 2. Green drake, found among stones by river-sides, has a yellow body ribbed with green, is long and slender, with wings like a butterfly, his tail turns on his back, and from May to midsummer is very useful. 3. Oak-fly found in the body of an old oak, or ash, with its head downwards, is of a brown colour, and excellent from May to September. 4. Palmer-fly or worm, rather a hairy caterpillar, found on leaves of plants, and when it comes to a fly is excellent for trout. 5. Ant-fly, found in ant-hills from June to September. 6. The May-fly is to be found playing by the river-side, especially against rain. See Ephemera. 7. The black-fly is to be found upon every hawthorn after the buds are fallen off.

Almost the only sport in fishing that may be called so, is fly-fishing. The fly is either natural or artificial.

1. Natural flies are innumerable. The most usual

for this purpose are mentioned in the above lines. There are two ways to fish with natural flies; either on the surface of the water, or a little underneath it. In angling for chevin, roach, or dace, move not your natural fly swiftly, when you see the fish make at it; but rather let it glide freely towards him with the stream: but if it be in a still or slow water, draw the fly slowly sideways by him, which will make him eagerly pursue it.

2. The artificial fly is best used when the waters are so troubled by the winds, that the natural fly cannot be seen nor rest upon them. Of artificial flies there are reckoned no less than 12 sorts, of which the following are the principal. 1. For March, the dun-fly, made of dun-wool, and the feathers of the partridge's wing, or the body made of black wool, and the feathers of a black drake. 2. For April, the stone-fly, the body made of black wool, with a little yellow under the wings and tail. 3. For the beginning of May, the ruddy fly, made of red wool, and bound about with black silk, with the feathers of a black capon hanging dangling on his sides next his tail. 4. For June, the greenish fly, the body made of black wool, with a yellow list on either side, the wings taken off the wings of the buzzard, bound with black broken hemp. 5. The moorish fly, the body made of duskish wool, and the wings made of the blackish mail of a drake. 6. The tawny fly, good till the middle of June, the body made of tawny wool, the wings made contrary one against the other, of the whitish mail of a white drake. 7. For July, the wasp-fly, the body made of black wool, cast about with yellow silk, and the wings of drakes' feathers. 8. The steel-fly, good in the middle of July, the body made with greenish wool, cast about with the feathers of a peacock's tail, and the wings made of those of the buzzard. 9. For August, the drake-fly, the body made with black wool cast about with black silk, his wings of the mail of a black drake with a black head. The May-fly is also excellently imitated by the tackle-makers.

The best rules for artificial fly-fishing are; 1. To fish in a river somewhat disturbed with rain: or in a cloudy day, when the waters are moved by a gentle breeze; the south wind is best; and if the wind blows high, yet not so but that you may conveniently guard your tackle, the fish will rise in plain deeps: but if the wind is small, the best angling is in swift streams. 2. Keep as far from the water-side as may be; fish down the stream with the sun at your back, and do not disturb the water with your line. 3. Ever angle in clear rivers with a small fly and slender wings; but in muddy places use a larger. 4. When after rain the water becomes brownish, use an orange fly; in a clear day, a light-coloured fly; a dark fly for dark waters, &c. 5. Let the line be at least twice as long as the rod, unless the river is encumbered with trees. 6. For every sort of fly, have several of the same, differing in colour, to suit with the different complexions of several waters and weathers. 7. Have a nimble eye and active hand, to strike presently with the rising of the fish, or else he will be apt to throw out the hook. 8. Let the fly fall first into the water, and not the line, which will scare the fish. 9. In slow waters, or still places, cast the fly across the river, and let it sink a little in the water, and draw it gently back with the current. Salmon-flies should be made with their wings standing one behind the other, whether two or four. This fish delights in the gaudiest colours that can be; chiefly in the wings, which must be long, as well as the tail. The best wing is the hackle of the golden pheasant.

Pastes.—1. Take the blood of a sheep, and mix it with honey and flour to a proper consistence. 2. Take old cheese grated, a little butter sufficient to work it, and colour it with saffron; in winter use rusty bacon instead of butter. 3. Crumbs of bread chewed or worked with honey or sugar, moistened with gum-water. 4. Bread chewed, and worked in the hand till it becomes stiff, which with a little cotton wool to make it stick on the hook is the best of all.

Worms.—1. The earth-bob, found in sandy ground after ploughing; it is white, with a red head, and bigger than a gentle; another is found in heathy ground with a blue head. Keep them in an earthen vessel well covered, and a sufficient quantity of the mould they harbour in. They are excellent from April to November. 2. Gentles, to be had from putrid flesh; let them lie in wheat-bran a few days before used. 3. Flag-worms, found in the roots of flags: they are of a pale yellow colour, are longer and thinner than a gentle, and must be scoured like them. 4. Cow-dung, bog, or clap-bait, found under cow-dung from May to Michaelmas; it is like a gentle, but larger. Keep it in its native earth like the earth-bob. 5. Cadis-worm, or cod-bait, found under loose stones in shallow rivers: they are always covered with a case of sticks or small gravel, and when drawn out of their case are yellow, bigger than a gentle, with a black or blue head, and are in season from April to July. Keep them in flannel bags. 6. Lob-worm, found in gardens: it is very large, and has a red head, a streak down the back, and a flat broad tail. 7. Marsh worms, found in marshy ground; keep them in moss ten days before you use them: their colour is a blueish red; are a good bait from March to Michaelmas. 8. Brandling or red-worms, found in rotten dunghills and tanners' bark; they are red or rather striped worms, very good for all small fish, have sometimes a yellow tail, or a smaller sort are called tag-tails or gilt-tails, they have not the annular stripe of the brandling.

Fish and Insects.—1. Minnow. 2. Gudgeon. 3. Roach. 4. Dace. 5. Smelt. 6. Yellow frog. 7. Snail slit. 8. Grasshopper.

Floats, are little appendages to the line, used for fishing at bottom, and serving to keep the hook and bait suspended at the proper depth, to discover when the fish have hold of them, &c. Of these there are many kinds: some made of quills, which are the best for slow waters; but for strong streams sound cork, without flaws or holes, bored through with a hot iron, into which is put a quill of a fit proportion, is preferable; the cork should be shaped to a pyramidal form, and made smooth.

The fishing-hook, in general, ought to be long in the shank, somewhat thick in the circumference, the point even and straight; the bend should be in the shank. For setting the hook on, use strong but small silk, laying the hair on the inside of the hook; for if it is on the outside, the silk will fret and cut it asunder.

FISSURE *of the bones*, in surgery, is when they are divided either transversely or longitudinally, not quite

through, but cracked after the manner of glass, by any external force. See SURGERY.

FISTULA, in the ancient music, an instrument of the wind-kind, resembling our flute, or flageolet. See FLUTE.

FISTULA, in surgery, a deep, narrow, and callous ulcer, generally arising from abscesses. See SURGERY.

FISTULARIA, pipe-fish, a genus of the order abdominales. The generic character is, snout cylindric; mouth terminal; body lengthened; gill-membrane seven-rayed.

1. Fistularia tabacaria, or slender fistularia. This highly singular fish seems to have been first described by Marcgrave in his Natural History of Brasil, under the name of petimbuaba. He informs us that it grows to the length of three or four feet, and is of a shape resembling that of an eel, with the mouth toothless and pointed, and the upper lip longer than the lower; the head about nine inches long, from the eyes to the tip of the mouth; the eyes are large and ovate, with a bright-blue pupil and silvery iris, marked on the fore and hind part by a red spot; the skin smooth, like that of an eel, and of a liver-colour marked both above and on each side by a row of blue spots, with greenish ones intermixed. The appearance of the tail is highly singular, being pretty deeply forked, as in the generality of fishes, while from the middle of the furcature springs a very long and thickish bristle or process, of a substance resembling that of a whalebone, and gradually tapering to a fine point. A variety has been observed by Dr. Bloch, in which this part was double, and the snout serrated on each side. This variety, or perhaps sexual difference, appears from the observations of Commerson, detailed by Cepede, to be of a brown colour above, and silvery beneath, but without the blue spots so remarkable on the smooth-snouted kind. The count de Cepede informs us that the spine of this fish is of a very peculiar structure; the first vertebra being of immoderate length, the three next much shorter, and the rest gradually decreasing as they approach the tail: he adds that there are no visible ribs.

This species is said to live chiefly on the smaller fishes, sea-insects, and worms, which the structure of its snout enables it readily to obtain by introducing that part into the cavities of the rocks, under stones, &c. where those animals are usually found.

2. Fistularia Chinensis, or Chinese fistularia. Length from three feet to four feet; general shape like that of an eel, but the body thicker in proportion than in the preceding species: head lengthened into a strong cartilaginous, or rather bony and laterally compressed tubular snout, much broader than in the former species: mouth small; eyes rather large; scales of moderate size, strong, and much resembling in their structure those of the genera perca and chætodon; from the middle of the back to the dorsal fin run several strong, short, and rather distant spines: dorsal and anal fin of similar shape, and placed opposite each other, pretty near the tail, which is short, rounded, and marked by a pair of black stripes; pectoral fins rounded: ventral small, and placed considerably beyond the middle of the body: general colour pale reddish-brown, with several deep or blackish spots on various parts of the body, and three or four pale or whitish longitudinal stripes on each side, from the gills to the tail: fins pale yellow. Native of the Indian seas, preying on worms, sea-insects, &c. Though observed only in the tropical seas, yet its fossil impressions have been found under the volcanic strata of mount Bolca in the neighbourhood of Verona.

3. Fistularia paradoxa, paradoxical fistularia. A small species, described by Seba, and more accurately by Dr. Pallas. Length from two to four inches: body angular, and beset at the interstices of the lines with small spines: head small: eyes large, and situated at the base of the snout, which much resembles that of a syngnathus, and is long, slightly descending, straight, horny, compressed, sharp above, and bicarinated beneath: it is armed on each side, near the base, by a small conic spine. It is a native of the Indian seas.

FIT, in medicine, denotes much the same with paroxysm. See PAROXYSM.

FITS *of easy reflection and transmission.* See OPTICS.

FITCHEE', in heraldry, a term applied to a cross, when the lower end of it is sharpened into a point.

FIXED BODIES are those which bear a considerable degree of heat without evaporating, or losing any of their weight. See CHEMISTRY.

FIXED AIR. See AIR, CARBONIC ACID GAS, and CHEMISTRY.

FIXED STARS. See ASTRONOMY.

FLACOURTIA, a genus of the class and order dioecia polyandria. The male calyx is five-parted; corolla none; stamina very numerous. Female calyx many-leaved; corolla none; germen superior. Styles 5 to 9. Berry many-celled. There is one species, a small tree of Madagascar, bearing an eatable fruit in some degree resembling a plumb.

FLAG, a general name for colours, standards, ancients, banners, ensigns, &c. which are frequently confounded with each other.

The fashion of pointed, or triangular flags, as now used, came from the Mahometan Arabs, or Saracens, upon their seizing of Spain, before which time all the ensigns of war were stretched, or extended on cross pieces of wood, like the banners of a church. The pirates of Algiers, and throughout the coasts of Barbary, bear an hexagonal flag.

FLAG, is more particularly used at sea, for the colours, ancients, standards, &c. borne on the top of the masts of vessels, to notify the person who commands the ship, of what nation it is, and whether it is equipped for war or trade.

The admiral in chief carries his flag on the main top; and the vice-admiral on the fore-top; and the rear-admiral on the mizen top.

When a council of war is to be held at sea, if it is on board the admiral, they hang a flag in the main shrouds; if in the vice-admiral, in the fore shrouds; and if in the rear-admiral, in the mizen shrouds.

Beside the national flag, merchant-ships frequently bear lesser flags on the mizen mast, with the arms of the city where the master ordinarily resides: and on the foremast, with the arms of the place where the person who freights them lives.

To lower, or strike the FLAG, is to pull it down upon the cap, or to take it in, out of respect, or submission, due from all ships or fleets inferior, to those any way justly

their superiors. To lower or strike the flag in an engagement is a sign of yielding.

The way of leading a ship in triumph is to tie the flags to the shrouds or the gallery, in the hind part of the ship, and let them hang down towards the water, and to tow the vessels by the stern.

To heave out the FLAG, is to put out, or put abroad, the flag.

To hang out the white FLAG, is to ask quarter; or it shows when a vessel is arrived on a coast, that it has no hostile intention, but comes to trade, or the like. The red flag is a sign of defiance and battle.

FLAG-OFFICERS, those who command the several squadrons of a fleet, such as the admirals, vice-admirals, and rear-admirals.

The flag-officers in British pay are the admiral, vice-admiral, and rear-admiral, of the white, red, and blue. See the article ADMIRAL.

FLAG-SHIP, a ship commanded by a general or flag-officer, who has a right to carry a flag, in contradistinction to the secondary vessels under its command.

FLAG-STAVES, are staves set on the heads of the top-gallant-masts, serving to let fly, or unfurl, the flag.

FLAGS, in falconry, are the feathers in a hawk's wing, near the principal ones.

FLAG is used for sedge, a kind of rush; and for the upper part of turf, pared off to burn.

FLAG-FLOWER, in botany, a plant called by botanists iris. See IRIS.

Corn-FLAG. See GLADIOLUS.

FLAGELLANTES, *whippers*, in church history, certain enthusiasts in the 13th century, who maintained, that there could be no remission of sins without flagellation, or whipping. Accordingly, they walked in procession, preceded by priests carrying the cross, and publicly lashed themselves, till the blood dropped from their naked backs.

FLAGELLARIA, a genus of the hexandria monogynia class and order of plants: flower petals none; the perianthium is divided into six segments, and the fruit is a roundish berry, containing a single seed. There are two species, shrubs of the East Indies.

FLAGEOLET, or *flajeolet*, a little flute, used chiefly by shepherds, and country people. It is made of box, or any other hard wood, and sometimes of ivory; and has six holes besides that at the bottom, the mouth piece, and that behind the neck.

FLAIL, an instrument for threshing corn. See HUSBANDRY.

A flail consists of the followng parts: 1. The hand-staff, or piece held in the thresher's hand. 2. The swiple, or that part which strikes out the corn. 3. The caplins, or strong double leathers, made fast to the tops of the hand-staff and swiple. 4. The middle-hand, being the leather-thong, or fish-skin, that ties the caplins together.

FLAIR, in the sea-language. When a ship is housed in near the water, so that the work above hangs over too much, it is said to flair over. This makes the ship more roomy aloft, for the men to use their arms.

FLAME, in physiology: when oxygen gas is decomposed slowly, the heat is imperceptible, because the caloric is dissipated as soon as generated. When the decomposition goes on faster, the bodies concerned become sensibly warm. A quicker decomposition of the gas heats the bodies so as to render them red hot, which state is called ignition: and when the process is attended with the production of certain fluids, as hydrogen, &c. and the decomposition of oxygen air affords a sufficient developement of caloric, then the fluids themselves are ignited, and decomposed, which constitutes flame, and is thence termed inflammation. When a candle is first lighted, which must be done by the application of actual flame, a degree of heat is given to the wick sufficient to destroy the affinity of its constituent parts: some of the tallow is instantly melted, volatilized, and decomposed, its hydrogen takes fire, and the candle melts. As this is destroyed by combustion another portion melts, rises and supplies its place, and undergoes a like decomposition. In this way combustion is maintained in a candle. The most brilliant flame is exhibited in oxygen gas, and in this flames of different colours may be produced: thus a mixture of nitrate of strontia and charcoal powder, previously ignited, burns with a rose-coloured flame: one part of boracic acid, and three of charcoal mixed, will burn green: one part of nitrate of barytes and four of charcoal powder burn with a yellow flame: equal parts of nitrate of lime and charcoal powder burn orange-red.

FLAMINGO, in ornithology. See PHŒNICOPTERUS.

FLANEL, or *flannel*, a kind of slight, loose, woollen stuff, composed of a woof and warp, and woven on a loom with two treadles, after the manner of bays. Dr. Black assigns as a reason why flannel and other substances of the kind keep our bodies warm, that they compose a rare and spongy mass, the fibres of which touch each other so slightly, that the heat moves slowly through the interstices, which being filled only with air, and that in a stagnant state, gives little assistance in conducting the heat. Count Rumford, however, has inquired farther into the matter, and finds that there is a relation betwixt the power which the substances usually worn as clothing have of absorbing moisture, and that of keeping our bodies warm. Having provided a quantity of each of those substances mentioned below, he exposed them, spread out upon China plates, for the space of 24 hours to the warm and dry air of a room, which had been heated by a German stove for several months, and during the last six hours had raised the thermometer to 85° of Fahrenheit: after which he weighed equal quantities of the different substances with a very accurate balance. They were then spread out upon a China plate, and removed into a very large uninhabited room upon the second floor, where they were exposed 48 hours upon a table placed in the middle of the room, the air of which was at 45° of Fahrenheit. At the end of this space they were weighed, and then removed into a damp cellar, and placed on a table in the middle of the vault, where the air was at the temperature of 45°, and which by the hygrometer seemed to be fully saturated with moisture. In this situation they were suffered to remain three days and three nights; the vault being all the time hung round with wet linen cloths, to render the air as completely damp as possible. At the end of three days they were weighed, and the weights at the different times were found as in the following table.

	Weight after being dried in the hot room.	Weight after coming out of the cold room.	Weight after remaining 72 hours in the vault.
Sheep's wool	1000 parts	1084	1163
Beaver's fur		1072	1125
The fur of a Russian hare		1065	1115
Eider down		1067	1112
Silk { Raw single thread		1057	1107
Silk { Ravellings of white taffety		1054	1103
Linen { Fine lint		1046	1102
Linen { Ravellings of fine linen		1044	1082
Cotton wool		1043	1089
Ravellings of silver lace		1000	1000

On these experiments our author observes, that though linen, from the apparent ease with which it receives dampness from the atmosphere, seems to have a much greater attraction for water than any other; yet it would appear, from what is related above, that those bodies which receive water in its inelastic form with the greatest ease, or are most easily wet, are not those which in all cases attract the moisture of the atmosphere with the greatest avidity. "Perhaps (says he), the apparent dampness of linen to the touch arises more from the ease with which that substance parts with the water it contains, than from the quantity of water it actually holds: in the same manner as a body appears hot to the touch, in consequence of its parting freely with its heat; while another body, which is really at the same temperature, but which withholds its heat with greater obstinacy, affects the sense of feeling much less violently."

FLANKS *of an army*, are the troops encamped on the right and left, as the flanks of a battalion are the files on the right and left.

FLANKS *of a bastion*, in fortification, that part which joins the face to the curtin. See FORTIFICATION.

FLANKED, in heraldry, is used by the French to express parti per saltier. Coats, however, makes it to be the same with flanch.

FLAT, in the sea-language. To flat in the fore-sail, to hale it in by the sheet, as near the ship's side as possible; which is done when a ship will not fall off from the wind.

FLAT, in music, a character which being placed before a note signifies that the note is to be sung or played half a tone lower than its natural pitch.

FLAT double, or double flat, a character compounded of two flats, and signifying that the note before which it is placed is to be sung or played two semitones lower than its natural pitch.

FLATULENCY. See MEDICINE.

FLAX. See LINUM.

FLEA. See PULEX.

FLEAM, in surgery and farriery, an instrument for letting a horse or other animal blood. See FARRIERY.

FLEECE, the covering of wool, shorn off the bodies of sheep. See WOOL.

FLEECE, *order of the golden*, an order of knighthood instituted by Philip II. duke of Burgundy. These knights at first were twenty-four, besides the duke himself, who reserved the nomination of six more: but Charles V. increased them to fifty. He gave the guardianship of this order to his son Phillip king of Spain, since which the Spanish monarchs are chiefs of the order. The knights had three different mantles ordained them at the grand solemnity, the collar, and fleece.

FLEECY-HOSIERY, a very useful kind of manufacture, in which fine fleeces of wool are interwoven into a cotton piece of the common stocking texture. The following is the specification of the patent granted to Mr. Holland, of Broad-street, Bloomsbury, in the county of Middlesex, for a method of making stockings, socks, waistcoats, and other clothing, for persons afflicted with complaints requiring warmth, and for common use in cold climates, and for making false or downy calves in stockings.

"Having in the common stocking-frame, twisted silk, cotton yarn, flaxen or hempen thread, worsted or woollen yarn, or any such-like twisted or spun materials, begin the work in the common manner of manufacturing hosiery, and having worked one or more course or courses in the common way, begin to add a coating, thus: draw the frame over the arch, and then hang wool or jersey, raw or unspun, upon the beards of the needles, and slide the same off their beards upon their stems, till it comes exactly under the nibs of the sinkers; then sink the jacks and sinkers, and bring forward the frame, till the wool or jersey is drawn under the beards of the needles, and having done this, draw the frame over the arch, and place a thread of spun materials upon the needles (under the nibs of the sinkers), and proceed in finishing the course in the usual way of manufacturing hosiery with spun materials. Any thing manufactured in this way has, on the one side, the appearance of common hosiery, and on the other side the appearance of raw wool. The raw or unspun materials may be worked in with every course, or with every second, third, or other course or courses, in quantity proportioned to the warmth and thickness required. The above-mentioned raw or unspun materials may be fixed also thus: having drawn the frame over the arch, hang them upon the beards of the needles, slide them off the beards upon their stems, and without sinking the jacks and sinkers, draw the frame off the arch, and bring the raw or unspun materials forward under the beards of the needles; then draw the same over the arch, and proceed in finishing the course, as before directed. The said raw or unspun materials may be fixed likewise thus: hang them upon the beards of the needles, without having the frame over the arch, and slide them off their beards upon their stems; then bring forward the frame till the raw or unspun materials are drawn under the beards of the needles, and, having done this, draw the frame over the arch, and proceed in finishing the course as before directed. Hosiery may be coated by any of these methods, not only with wool or jersey, but also with silk, cotton, flax, hemp, hair, or other things of the like nature, raw or unspun, but the method first described fixes them most firmly. The common stocking-frame is mentioned above, but any other frame, upon a similar principle, may answer the purpose. The method of making the false or downy calves in stockings, is by working raw or unspun wool, or jersey, or any other raw or unspun materials, into the calves of stockings, in the different

methods before described, and to any required form or thickness." The latter use to which this invention is applied, we may be allowed to say, is somewhat ludicrous.

FLEET, commonly implies a company of ships of war, belonging to any prince or state; but sometimes it denotes any number of trading-ships, employed in a particular branch of commerce.

In sailing, a fleet of men of war is usually divided into three squadrons; the admiral's, the vice-admiral's, and the rear-admiral's squadron, all which, being distinguished by their flags and pendants, are to put themselves, and as near as may be, to keep themselves in their customary places, viz. the admiral, with his squadron, to sail in the van, that so he may lead the way to all the rest in the day-time, by the sight of his flag on the maintopmast-head; and in the night-time by his lights or lanterns. The vice-admiral and his squadron are to sail in the centre, or middle of the fleet. The rear-admiral, and the ships of his squadron, to bring up the rear. But sometimes other divisions are made; and those composed of the lighter ships and best sailers, are placed as wings to the van, centre, and rear.

Merchant-fleets generally take their denomination from the place they are bound to, as the Turkey fleet, East India fleet, &c. These, in time of peace, go in fleets for their mutual aid and assistance: in time of war, besides this security, they likewise procure convoys of men of war, either to escort them to the places whither they are bound, or only a part of the way, to a certain place or latitude, beyond which they are judged out of danger of privateers, &c.

Fleet, a prison in London, to which persons are committed for contempt of the king and his laws, particularly of his courts of justice: or for debt, where any person will not, or is unable to pay his creditors. There are large rules, and a warden belonging to the fleet prison, which had its name from the float or fleet of the river or ditch on the side whereof it stands.

FLESH, in anatomy, a fibrous part of an animal body, soft and bloody, being that of which most of the other parts are composed, and by which they are connected together: or, more properly, it is that part of the body where the blood-vessels are so small, as only to retain blood enough to preserve their colour red.

By chemical analysis it is found that muscular flesh is composed of a great number of fibres or threads, commonly of a reddish or whitish colour; but its appearance is too well known to require any description. Hitherto it has not been subjected to a perfectly accurate chemical analysis. Mr. Thouvenel, indeed, has published a very valuable dissertation on the subject; and it is to him that we are indebted for almost all the facts known concerning the composition of muscle. Some additions have also been made by M. Fourcroy. And Mr. Hatchett has not neglected this part of the subject in his interesting dissertation on animal substances.

It is scarcely possible to separate the muscle from all the other substances with which it is mixed. A quantity of fat often adheres to it closely; blood pervades the whole of it: and every fibre is enveloped in a particular thin membranous matter, which the anatomists distinguish by the name of cellular substance. The analysis of the muscle, then, cannot be supposed to exhibit an accurate view of the composition of pure muscular fibre, but only of muscular fibre not perfectly separated from other substances.

When a muscle is cut in small pieces, and well washed with water, the blood and other liquids contained in it are separated, and part of the muscular substance is also dissolved. The muscle, by this process, is converted into a white fibrous substance, still retaining the form of the original body. The water assumes the colour which results from mixing water with some blood. When heated it coagulates; brown flakes swim on the surface, consisting of albumen combined with the colouring matter of the blood; some fibrina likewise precipitates. If the evaporation is continued, more albumen precipitates, and at last the whole assumes the form of a jelly. When evaporated to dryness, and treated with alcohol, the gelatine thus formed, together with a little phosphat of soda and of ammonia, remain undissolved; but the alcohol dissolves a peculiar extractive matter, first observed by Thouvenel. This matter may be obtained by evaporating the alcohol to dryness. It has a reddish-brown colour, a strong acrid taste, and an aromatic odour. It is soluble both in water and alcohol; and when its watery solution is very much concentrated, it assumes an acid and bitter taste. It swells upon hot coals, and melts, emitting an acid and penetrating smell. It attracts moisture from the air, and forms a saline efflorescence. In a hot atmosphere it becomes sour and putrefies. When distilled it yields an acid partly combined with ammonia.

If the muscle, after being thus treated with cold water, is boiled for a sufficient time in water, an additional portion of the same substances is separated from it. Some albumen collects on the surface in the form of scum, accompanied with melted fat. The water, when sufficiently concentrated by evaporation, assumes the form of a jelly. When evaporated to dryness, and treated with alcohol, the gelatine and phosphoric salts remain, while the extractive matter of Thouvenel is dissolved, and may be obtained by evaporating to dryness. It is by this process that it is procured in a sufficient quantity for examination, cold water abstracting only a very small portion from the muscle.

The muscle, thus treated with water, is left in the state of grey fibres, insoluble in water, and becoming brittle when dry. This substance possesses all the properties of fibrina.

From these facts, ascertained by Thouvenel and Fourcroy, it appears that the muscles are composed chiefly of fibrina, to which they owe their fibrous structure and their form (see Fibrina); and that they contain also

2. Albumen
3. Gelatine
4. Extractive
5. Phosphat of soda
6. Phosphat of ammonia
7. Phosphat of lime and carbonat of ditto.

For the discovery of the last ingredients we are indebted to Mr. Hatchett, who found that 500 parts of beef-muscle left, after combustion, a residuum of 25.6 parts, consisting chiefly of these salts. When muscles

are long boiled in water, Mr. Hatchett found that the greater part of the phosphat of lime, as well as of the alkaline phosphats, was dissolved; for the muscle, after this treatment, when dissolved in nitric acid, yielded scarcely any phosphat of lime; whereas if it was dissolved directly in nitric acid, a precipitate of phosphat of lime was thrown down by ammonia. Hence it would appear, either that the phosphat of lime is united to gelatine, or that it is rendered soluble by means of it. The carbonat of lime still remains after the action of water, and is converted into oxalat when the muscle is treated with nitric acid.

The muscles of different animals differ exceedingly from each other in their appearance and properties, at least as articles of food; but we know little of their chemical differences. The observations of Thouvenel alone were directed to that object, and they are imperfect. The flesh of the ox contains, according to him, the greatest quantity of insoluble matter, and leaves the greatest residuum when dried: the flesh of the calf is more aqueous and mucous: the land and water turtle yields more matter to water than the muscle of the ox; but Thouvenel ascribes the difference to foreign bodies, as ligaments, &c. mixed with the muscle of the turtle: snails yield to water a quantity of matter intermediate between that given by beef and veal: with them the muscles of frogs, cray fish, and vipers, agree nearly in this respect; but the muscles of fresh-water fish, notwithstanding their softness, yield a considerably smaller proportion.

When meat is boiled, it is obvious that the gelatine, the extractive, and a portion of the salts, will be separated, while the coagulated albumen and fibrina will remain in a solid state. Hence the flavour and the nourishing nature of soups is derived from the extractive and gelatine. When meat is roasted, on the other hand, all these substances continue in it, and the taste and odour of the extractive are greatly heightened by the action of the fire. Hence the superior flavour of roasted meat.

FLEVILLEA, a genus of the hexandria order, in the diœcia class of plants. The male calyx and corolla are quinquefid; the stamina five; the nectarium five converging filaments. The female calyx is quinquefid; there are three styli; the fruit a hard trilocular barky apple.

FLEXIBLE, in physics, a term applied to bodies capable of being bent or diverted from their natural figure or direction.

FLEXION, in anatomy, is applied to the motion by which the arm or any other member of the body is bent. It is also applied to the muscles, nerves, &c.

Flexion, or *flexure of curves*. See the article Flexure.

FLEXOR. See Anatomy.

FLEXURE or curves, in the higher geometry, is used to signify that a curve is both concave and convex, with respect to a given right line.

FLIGHT, is evading the course of justice by a man's voluntarily withdrawing himself. On an accusation of treason or felony, or even of petty-larceny, if the jury find that the party fled for the same, he shall forfeit his goods and chattels, although he be acquitted of the offence; for the very flight itself is an offence, carrying with it a strong presumption of guilt, and is at least an endeavour to elude and stifle the course of justice prescribed by the law. But now the jury very seldom find the flight; such forfeiture being looked upon, since the vast increase of personal property, as too large a penalty for an offence, to which a man is prompted by the natural love of liberty. 4 Black. 387.

FLINT. See Silica.

Flint, a stone very useful in modern war, is found in pieces of different sizes, and usually of a figure more or less globular, commonly among chalk, and often arranged in some kind of order.

Its texture is compact. Its fracture smooth, conchoidal. The stones are always covered by a white crust. Specific gravity from 2.58 to 2.63. Colour varies from honey-yellow to brownish-black. Very brittle, and splits into splinters in every direction. Two pieces of flint rubbed smartly together phosphoresce, and emit a peculiar odour. When heated it decrepitates, and becomes white and opaque. When exposed long to the air it often becomes covered with a white crust. A specimen of flint analysed by Klaproth contained,

98.00	silica,
.50	lime,
.25	alumina,
0.25	oxide of iron,
1.00	water.
100.00	

Vauquelin obtained from another,

97	silica,
1	alumina and iron,
98	

Another specimen analysed by Dolomieu was composed of,

97	silica,
1	alumina, and oxide of iron
2	water.
100.	

The whole crust with which flint is enveloped consists of the same ingredients, and a little carbonat of lime. Water is essential to flint; for when it is separated by heat the stone loses its properties.

The manufacture of gun-flints is chiefly confined to England, and two or three departments of France. The operation is exceedingly simple, and a good workman will make 1000 flints a day. The whole art consists in striking the stone repeatedly with a kind of mallet, and bringing off at each stroke a splinter, sharp at one end, and thicker at the other. The splinters are afterwards shaped at pleasure, by laying the line at which it is wished they should break, upon a sharp instrument, and then giving it small blows with a mallet.

FLOAT *of a fishing-line*, the cork or quill that floats or swims above the water.

Float also signifies a certain quantity of timber bound together by rafters and athwart, and put into a river to be conveyed down the stream; and even sometimes to carry burdens down the river with the stream.

Float-boards, those boards fixed to water-wheels of undershot mills, serving to receive the impulse of the

stream, whereby the wheel is carried round. See Mill-work.

FLOOD, among seamen, is when the tide begins to come up, or the water begins to rise: then they call it young flood; after which it is quarter-flood, half-flood, and high-flood.

Flood-mark, the mark which the sea makes on the shore, at flowing-water, and the highest tide: it is also called high-water mark.

FLOOKING, among miners, a term used to express a peculiarity in the load of a mine. The load or quantity of ore is frequently intercepted in its course, by the crossing of a vein of earth or stone, or some different metallic substance; in which case the load is moved to one side, and this transient part of the land is called a flooking.

FLORIN, is sometimes used for a coin, and sometimes for a money of account.

Florin, as a coin, is of different values, according to the different metals and different countries where it is struck. The gold florins are most of them of a very coarse alloy, some of them not exceeding thirteen or fourteen carats, and none of them seventeen and a half. As to silver florins, those of Holland are worth about 1*s.* 8*d.*: those of Genoa were worth 8¼*d.* sterling. See Coin.

FLORINIANS, *floriniania*, in church history, a sect of heretics of the second century, so denominated from their leader Florinus, who made God the author of evil. They are a species of the gnostics, but deny the judgment and resurrection, and hold that our Saviour was not born of a virgin. They were also called Borborites.

FLORIST, *florista*, according to Linnæus, is an author or botanist who writes a treatise called Flora, comprehending only the plants and trees to be found growing naturally in any place. However, in the more common acceptation of the word, florist signifies a person well skilled in flowers, their kinds and cultivation.

FLOS, in chemistry, the most subtile part of bodies, separated from the more gross parts by sublimation, in a dry form. See Chemistry.

FLOTSAM, Jestam, and Lagan. Flotsam is when a ship is sunk or cast away, and the goods float on the sea; jestam is when a ship is in danger of being sunk, and to lighten the ship the goods are cast into the sea, and the ship notwithstanding perishes; and lagan is when the goods so cast into the sea are so heavy that they sink to the bottom, and therefore the mariners fasten to them a buoy or cork, or such other thing that will not sink, to enable them to find them again. 5 Rep. 106. b. The king shall have flotsam, jestam, and lagan, when the ship is lost, and the owners of the goods are not known, but not otherwise. F. N. B. 122. Where the proprietors of the goods may be known, they have a year and a day to claim flotsam.

FLOUR, the meal of wheat-corn, finely ground and sifted.

Flour-mills are put in motion by the application of various forces: sometimes the first mover is wind, at others water, at others the force of steam, at others the muscular energy of animals. The mechanism of the grinding part of most of these is nearly the same, and pretty well understood: we shall here give an account of the construction of the several figures in the plate.

Fig. 1. (Plate LVIII. Flour-mills) represents a common pair of flour-stones; A, is a trundle fixed to a spindle B, so as to turn with it; the lower end of this spindle turns in a brass socket fixed in the beam, CD, called the bridge-tree; and the upper end of this spindle turns in a wooden bush, fixed into the middle of the nether millstone, which lies on the floor, EF. The top part of the spindle, above the bush, is square, and goes into a strong iron cross, *a b c d*, fig. 2, called the crow: the four ends of this crow are let into the under-surface of the running-millstone, shown upside downwards in fig. 2, so that when the spindle is turned by the trundle A, the stone will turn with it. The end, *c*, of the bridge tree, fig. 1, is jointed into the post, G: the other goes through a long mortice in the post, H, and has an iron rod, I, fixed to it; on the top of this are a screw and hand-nut, K, by turning of which the two mill-stones can be brought nearer together, and vice versa, so as to grind finer or coarser. The two stones are enclosed in an octagonal box, LM, which is about two inches more across than the diameter of the running-stone. Upon the top of this box is a frame to support the hopper, N, to which is hung the shoe or spout, O, by a strap fastened to the back of it; to the other end of the shoe a line, *e*, is fastened, the drawing of which regulates the aperture between the shoe and the hopper, and the quantity of corn that comes from the hopper: this is otherwise done by a small shuttle, *f*, in the front of the hopper: to the end of the shoe, O, a small line, *g*, is fastened, the other end of which is tied to a wooden spring, *h*. The top of the spindle, B, has a small square hole in it, into which is put the feeder, P: this feeder, as the spindle turns round, pushes the shoe from it, and it is brought back by the spring, *h*, three times in each revolution of the stone and spindle, and so causes the corn constantly to run down from the hopper, through the upper millstone, and by the motion thereof it gets between the stones, and is ground. The great velocity of the upper or running stone creates a centrifugal force in the corn, and throws it farther from the centre, till it is thrown quite out at the circumference of the stone in the form of flour, and passes through a spout, Q, to a meal-chest below. The grinding surface of both stones, in order to bruise and cut the corn, are hollowed into straight groves, as shown in fig. 2.

Fig. 3, is a wire bolting-machine; A is the riger and band by which it is turned, from a drum in some part of the mill; on its spindle rows of brushes are fixed, as shown in fig. 4. These brushes turn round within a cylindrical frame, CD, fig. 3; withinside of this frame is nailed wire-cloth, which is very fine at the end D, and gets coarser as it goes towards C; this frame is fixed from turning round, by its ends going into the framing of the box in which the whole is contained, and is farther steadied by four chains, EEE, fastened to the top of the box: at one end of the box is a square hole for the feeding-trough, G, to pass through: this trough is loosely connected to the trough H, (which brings the flour from the floor above) by leather nailed round their ends: the trough G is supported on the end of a crooked piece of wood, *a*, moving round a pin as a centre, at *d*; when the

brushes are turned round with a great velocity, the stubs, *e*, in the end of the spindle, shown in fig. 4, move the trough, G, to one side, and its line, *f*, the spring, *c*, immediately pulls it back again. This shakes the flour down through it into the cylinder, CD, and the brushes rubbing it round against the wire, that sort which is fine enough passes through into the hopper, K: the rest passes on in the cylinder, and goes through into the hoppers, L and M, according to the different degrees of fineness, till at last the bran falls out at a hole in the end, into the hopper, N: these hoppers have troughs, connecting with their bottoms, going through the floor, and the mouths of the flour-sacks are hooked to them in the room below, to receive the different sorts of flour and the bran.

Fig. 5 is the common bolting-cloth; A, is the riger turned by a strap; on its axis, within the box, is a reel, fig. 6, over which is put a bag, open at the ends, called the bolting-cloth, CD, in fig. 5, and tied to the reel by its ends; it is woven very fine at the end, D, and gradually gets coarser towards the end, C; the feeding-troughs, G and H, are the same as already described in fig. 4; by the side of the reel are three wooden bars, *ab*, and another behind, fixed in the box by their ends. When the reel is turned with a great velocity, the four arms, *cdef*, fig. 6, shake the trough, G, and cause the flour to run regularly down into the bolting-cloth, and the centrifugal force causes the cloth to swing against the three sticks, *ab*, beats the fine flour through the cloth into the hopper, K, and the other sorts into the hoppers LMN; the bran falls out at the end of the cloth into the hopper, O, and goes through the end of the box and the floor, in a wooden trough, to the end of which a sack is hooked to receive it in the floor beneath. There are troughs from the bottom of the hopper, KLMN, to convey the flour to the sacks, as described in fig. 4.

We shall hereafter, under the article MILLS, give a more detailed account of the theory of mills, and of the means by which they may be worked with the greatest advantage, and with the least expense of power.

FLOWER, *flos*, among botanists and gardeners, the most beautiful part of trees and plants, containing the organs or parts of fructification. See BOTANY.

FLOWERS, *preserving of.* The method of preserving flowers in their natural beauty through the whole year has been much sought after by many people. Some have attempted it by gathering them when dry, and not too much opened, and burying them in dry sand; but this, though it preserves their figure well, takes off from the liveliness of their colour. Muntingius prefers the following method to all others. Gather roses, or other flowers, when they are not yet thoroughly open, in the middle of a dry day: put them into a good earthen vessel glazed within; fill the vessel up to the top with them; and when full, sprinkle them over with some good French wine, with a little salt in it; then set them by in a cellar, tying down the mouth of the pot. After this they may be taken out at pleasure; and on setting them in the sun, or within reach of the fire, they will open as if growing naturally; and not only the colour, but the odour also, will be preserved.

The flowers of plants are by much the most difficult parts to preserve in any tolerable degree of perfection; of which we have instances in all the collections of dried plants, or horti sicci. In these the leaves, stalks, roots, and seeds of the plants, appear very well preserved; the strong texture of these parts making them always retain their natural form, and the colours in many species naturally remaining. But where these fade, the plant is little the worse for use as to knowing the species. But it is very much otherwise in regard to the petals: these are naturally by much the most beautiful parts of the plant to which they belong; but they are so much injured in the common way of drying, that they not only lose, but change their colours one into another, by which means they give occasion to many errors; and they usually also wither up, so as to lose their very form and natural shape. The primrose and cowslip kinds are very eminent instances of the change of colours in the flowers of dried specimens: for those of this class of plants easily dry in their natural shape; but they loose their yellow, and, instead of it, acquire a fine green colour, much superior to that of the leaves in their most perfect state. The flowers of all the violet kind lose their beautiful blue, and become of a dead-white: so that in dried specimens there is no difference between the blue-flowered violet and the white-flowered kinds.

Sir Robert Southwell has communicated to the world a method of drying plants, by which this defect is proposed to be in a great measure remedied, and all flowers preserved in their natural shape, and many in their natural colours. For this purpose, two plates of iron are to be prepared of the size of a large half-sheet of paper, or larger for particular occasions: these plates must be made so thick as not to be apt to bend; and there must be a hole made near every corner for the receiving a screw to fasten them close together. When these plates are prepared, lay in readiness several sheets of paper, and then gather the plants with their flowers when they are quite perfect. Let this be always done in the middle of a dry day; and then lay the plant and its flower on one of the sheets of paper doubled in half, spreading out all the leaves and petals as nicely as possible. If the stalk is thick, it must be pared or cut in half, so that it may lie flat; and if it is woody, it may be peeled, and only the bark left. When the plant is thus expanded, lay round about it some loose leaves and petals of the flower, which may serve to complete any part that is deficient. When all is thus prepared, lay several sheets of paper over the plant, and as many under it; then put the whole between the iron plates, laying the papers smoothly on one, and laying the other evenly over them: screw them close, and put them into an oven after the bread is drawn, and let them lie there two hours. After that, make a mixture of equal parts of aquafortis and common brandy; shake these well together, and when the flowers are taken out of the pressure of the plates, rub them lightly over with a camel's-hair pencil dipped in this liquor; then lay them upon fresh brown paper, and covering them with some other sheets, press them between this and other papers with a handkerchief till the wet of these liquors is dried wholly away. When the plant is thus far prepared, take the bulk of a nutmeg of gum-dragon; put this into a pint of fair water cold, and let it stand 24 hours; it will in this time be wholly dissolved: then dip a fine hair-pencil in this liquor, and with it daub over the back sides of the leaves, and lay them

carefully down on a half-sheet of white paper fairly expanded, and press them down with some more papers over these. When the gum-water is fixed, let the pressure and papers be removed, and the whole work is finished. The leaves retain their verdure in this case, and the flowers usually keep their natural colours. Some care, however, must be taken that the heat of the oven be not too great. When the flowers are thick and bulky, some art may be used to pare off their backs, and dispose the petals in a due order; and after this, if any of them are wanting, their places may be supplied with some of the supernumerary ones dried on purpose; and if any of them are only faded, it will be prudent to take them away, and lay down others in their stead: the leaves may be also disposed and mended in the same manner.

Another method of preserving both flowers and fruit sound through the whole year is also given by the same author. Take saltpetre, one pound; armenian bole, two pounds; clean common sand, three pounds. Mix all well together; then gather fruit of any kind that is not fully ripe, with the stalk to each; put these, one by one, into a wide-mouthed glass, laying them in good order. Tie over the top with an oil-cloth, and carry them into a dry cellar, and set the whole upon a bed of prepared matter of four inches thick in a box. Fill up the remainder of the box with the same preparation; and let it be four inches thick all over the top of the glass, and all round its sides. Flowers are to be preserved in the same sort of glasses, and in the same manner; and they may be taken up after a whole year as plump and fair as when they were buried.

Flower de lis, or *Flower de luce*, in heraldry, a bearing representing the lily, called the queen of flowers, and the true hieroglyphic of royal majesty; but of late it is become more common, being borne in some coats one, in others three, in others five, and in some semee, or spread all over the escutcheon in great numbers. The arms of France are, three flower-de-lis, or, in a field azure. It is observed by antiquarians, that flower de Louis is the proper name, having been borne by St. Louis on his shield, and that it is not a lily but an iris.

FLOWN sheets. in the sea language: a ship is said to sail with flown sheets when her sails are not haled home, or close to the blocks. The sheets are flown; that is, they are let loose, or run as far as they will.

FLUATS, in chemistry, salts first discovered by Scheele; they are distinguished by the following properties: (1) When sulphuric acid is poured upon them, they emit acrid vapours of fluoric acid, which corrode glass. (2) When heated, several of them phosphoresce. (3) They are not decomposed by heat, nor altered by combustibles. (4) They combine with silica by means of heat. Most of them are sparingly soluble in water.

Fluat of lime—flour spar. This mineral is found abundantly in different countries, particularly in Derbyshire. It is both amorphous and crystallized.

The primitive form of its crystals is the regular octahedron; that of its integrant molecules the regular tetrahedron. The varieties of its crystals hitherto observed amount to 9. These are the primitive octahedron; the cube; the rhomboidal dodecahedron; the cubo-octahedron, which has both the faces of the cube and of the octahedron; the octahedron wanting the edges; the cube wanting the edges, and either one face or two faces in place of each.

Werner divides this species into three sub-species.

1. *Earthy.* Colour greenish white or blueish green. Composed of earthy powder, somewhat agglutinated. Moderately heavy. Phosphoresces on hot coals. Found in Hungary in a vein. According to Pelletier, it is composed of

21	lime
15	alumina
31	silica
28	fluoric acid
1	phosphoric acid
1	muriatic acid
1	oxide of iron
1	water
99	

2. *Compact fluor.* Colour greenish grey, often spotted. Found in mass. Greasy. Fracture even, passing to the conchoidal. Scratches calcareous spar. Moderately heavy.

3. *Fluor spar.* The texture of fluat of lime is foliated. Causes single refraction. Very brittle. Specific gravity from 3.0943 to 3.1911. Colours numerous, red, violet, green, reddish yellow, blackish purple. Its powder thrown upon hot coals emits a blueish or greenish light. Two pieces of it rubbed in the dark phosphoresce. It decrepitates when heated. Before the blowpipe it melts into a transparent glass.

It admits of a polish, and is often formed into vases and other ornaments.

FLUENT, in fluxions, the following quantity, or that which is continually either increasing, or decreasing, whether line, surface, solid, &c. See Fluxion.

FLUID, in physiology, an appellation given to all bodies whose particles easily yield to the least partial pressure, or force impressed. See Hydrostatics.

FLUIDITY, is that state or affection of bodies which exhibits them in a liquid form.

All substances in nature, as far as we are acquainted with them, occur in one or other of the three following states; namely, the state of solids, of liquids, or of elastic fluids or vapours. It has been ascertained, that in a vast number of cases, the same substance is capable of existing successively in each of these states. Thus sulphur is usually a solid body; but when heated to 212° it is converted into a liquid; and at a still higher temperature (about 570°), it assumes the form of an elastic vapour of a deep-brown colour. Water also in our climate is usually a liquid; but when cooled down to 32°, it is converted into a solid body, and at 212° it assumes the form of an elastic fluid.

All solid bodies, a very small number excepted, may be converted into liquids by heating them sufficiently, and on the other hand, every liquid, except spirit of wine, is convertible into a solid body, by exposing it to a sufficient degree of cold. All liquid bodies may, by heating them, be converted into elastic fluids, and a great many solids are capable of undergoing the same change; and, lastly, the number of elastic fluids which by cold are condensible into liquids or solids, is by no means incon-

siderable. These facts have led philosophers to form this general conclusion, "that all bodies, if placed in a temperature sufficiently low, would assume a solid form; that all solids become liquids when sufficiently heated; and that all liquids, when exposed to a certain temperature, assume the form of elastic fluids." The state of bodies then depends upon the temperature in which they are placed; in the lowest temperatures they are all solid, in the higher temperatures they are converted into liquids, and in the highest of all they become elastic fluids. The particular temperatures at which bodies undergo those changes, are exceeding various, but they are always constant for the same bodies. Thus we see that heat produces changes on the state of bodies, converting them all, first into liquids, and then elastic fluids.

I. When solid bodies are converted by heat into liquids, the change in some cases takes place at once. There is no interval between solidity and liquidity; but in other cases a very gradual change may be perceived; the solid becomes first soft, and it passes slowly through all the degrees of softness, till at last it becomes perfectly fluid. The conversion of ice into water is an instance of the first change, for in that substance there is no intervening state between solidity and fluidity. The melting of glass, of wax, and of tallow, exhibits instances of the second kind of change; for these bodies pass through every possible degree of softness before they terminate in perfect fluidity. In general, those solid bodies which crystallize or assume regular prismatic figures, have no interval between solidity and fluidity, while those that do not usually assume such shapes have the property of appearing successively in all the intermediate states.

Solid bodies never begin to assume a liquid form till they are heated to a certain temperature; this temperature is constant in all. In the first class of bodies it is very well defined; but in the second, though it is equally constant, the exact temperature of fluidity cannot be pointed out with such precision on account of the intimate number of shades of softness through which the bodies pass before they acquire their greatest possible fluidity. But even in these bodies we can easily ascertain that the same temperature always produces the same degree of fluidity. The temperature at which this change from solidity to liquidity takes place, receive different names according to the usual state of the body thus changed. When the body is usually observed in a liquid state, we call the temperature at which it assumes the form of a solid, its freezing point, or congealing point. Thus the temperature in which water becomes ice, is called the freezing point of water; on the other hand, when the body is usually in the state of a solid, we call the temperature at which it liquifies its melting point: thus, 212° is the melting point of sulphur, 442° the melting point of tin.

The following table contains a list of the melting points of a considerable number of solid bodies.

Substance.	Melting point.
Lead	594°
Bismuth	576
Tin	442
Sulphur	212
Wax	142
Spermaceti	133
Phosphorus	100
Tallow	92
Oil of anise	50
Olive-oil	36
Ice	32
Milk	30
Vinegar	28
Blood	25
Oil of bergamot	23
Wines	20
Oil of turpentine	14
Sulphuric acid	36
Mercury	39
Liquid ammonia	46
Ether	46
Nitric acid	66

Before Dr. Black began to deliver his chemical lectures in Glasgow in 1757, it was universally supposed that solids were converted into liquids by a small addition of heat, after they had been once raised to the melting point, and that they returned again to the solid state on every small diminution of the quantity of heat necessary to keep them at that temperature. An attentive view of the phenomena of liquefaction and solidification gradually led this sagacious philosopher to observe their inconsistence with the then received opinions, and to form another, which he verified by direct experiments, and drew up an account of his theory, and the proofs of it, which was read to a literary society in Glasgow on April 23d, 1762; and every year after he gave a detailed account of the whole doctrine in his lectures.

The opinion which he formed was, that when a solid body is converted into a liquid, a much greater quantity of heat enters into it than is perceptible immediately after by the thermometer. This great quantity of heat does not make the body apparently warmer, but it must be thrown into it in order to convert it into a liquid; and this great addition of heat is the principal and most immediate cause of the fluidity induced. On the other hand, when a liquid body assumes the form of a solid, a very great quantity of heat leaves it without sensibly diminishing its temperature; and the state of solidity cannot be induced without the abstraction of this great quantity of heat. Or, in other words, whenever a solid is converted into a fluid, it combines with a certain dose of caloric, without any augmentation of its temperature; and it is this dose of caloric which occasions the change of the solid into a fluid. When the fluid is converted again into a solid, the dose of caloric leaves it, without any diminution of its temperature; and it is this abstraction which occasions the change. Thus the combination of a certain dose of caloric with ice causes it to become water, and the abstraction of a certain dose of caloric from water causes it to become ice. Water is then a compound of ice and caloric; and in general all fluids are combinations of the solid, to which they may be converted by the application of cold, and a certain dose of caloric.

Such is the opinion concerning the cause of fluidity taught by Dr. Black as early as 1762. Its truth was established by the following experiments:

First. If a lump of ice, at the temperature of 22°, is brought into a warm room, in a very short time it is heated to 32°, the freezing point. It then begins to melt; but the process goes on very slowly, and several hours

elapse before the whole ice is melted. During the whole of that time its temperature continues at 32°; yet as it is constantly surrounded by warm air, we have reason to believe that caloric is constantly entering into it. Now as none of the caloric is indicated by the thermometer, what becomes of it, unless it has combined with that portion of the ice which is converted into water, and unless it is the cause of the melting of the ice?

Dr. Black took two thin globular glasses, four inches in diameter, and very nearly of the same weight. Both were filled with water; the contents of the one was frozen into a solid mass of ice, the contents of the other were cooled down to 33°; the two glasses were then suspended in a large room at a distance from all other bodies, the temperature of the air being 47°. In half an hour the themometer placed in the water-glass rose from 33° to 40° or 7 degrees; the ice was at first 4 or 5 degrees colder than melting snow, but in a few minutes the thermometer applied to it stood at 32°. The instant of time when it reached that temperature was noted, and the whole left undisturbed for ten hours and a half. At the end of that time the whole ice was melted, except a very small spongy mass, which floated at the top, and disappeared in a few minutes. The temperature of the ice water was 40°.

Thus $10\frac{1}{2}$ hours were necessary to melt the ice, and raise the product to the temperature of 40°. During all this time it must have been receiving heat with the same celerity as the water-glass received it during the first half-hour. The whole quantity received then was 21 times 7, or 147°; but its temperature was only 40°: therefore 139 or 140 degrees had been absorbed by the melting ice, and remained concealed in the water into which it had been converted, its presence not being indicated by the thermometer.

That caloric, or heat, is actually entering into the ice, is easily ascertained by placing the hand on a thermometer under the vessel containing it. A current of cold air may be perceived descending from it during the whole time of the process.

But it will be said, perhaps, that the heat which enters into the ice does not remain there, but is altogether destroyed. This opinion is refuted by the following experiment.

Second. If, when the thermometer is at 22°, we expose a vessel full of water at 52° to the open air, and beside it another vessel full of brine at the same temperature, with thermometers in each, we shall find that both of them gradually lose caloric, and are cooled down to 32°. After this the brine (which does not freeze till cooled down to 0°) continues to cool without interruption, and gradually reaches 22°, the temperature of the air, but the pure water remains stationary at 32°. It freezes, indeed, but very slowly; and during the whole process its temperature is 32°. Now, why should the one liquid refuse all on a sudden to give out caloric and not the other? Is it not much more probable that the water, as it freezes, gradually gives out the heat which it had absorbed during its liquefaction; and that this evolution maintains the temperature of the water at 32°, notwithstanding what it parts with to the air during the whole process? We may easily satisfy ourselves that the water while congealing is constantly imparting heat to the surrounding air; for a delicate thermometer suspended above it is constantly affected by an ascending stream of air less cold than the air around. The following experiment, first made by Fahrenheit, and afterwards often repeated by Dr. Black and others, affords a palpable evidence, that such an evolution of caloric actually takes place during congelation.

Third. If, when the air is at 22°, we expose to it a quantity of water in a tall beer-glass, with a thermometer in it and covered, the water gradually cools down to 22° without freezing. It is therefore 10° below the freezing point. Things being in this situation, if the water is shaken, part of it instantly freezes into a spongy mass, and the temperature of the whole instantly rises to the freezing point, so that the water has acquired ten degrees of caloric in an instant. Now whence came these ten degrees? Is it not evident that it must have come from that part of the water which was frozen, and consequently that water in the act of freezing gives out caloric?

From many experiments made on water in these circumstances, it is found that the quantity of ice which forms suddenly on the agitation of water, cooled down below the freezing point, bears always a constant ratio to the coldness of the liquid before agitation. Thus when water is cooled down to 22° very nearly $\frac{1}{14}$ of the whole freezes; when the previous temperature is 27°, about $\frac{1}{28}$ of the whole freezes. In all cases when water is cooled down below 32°, it loses a portion of the caloric which is necessary to constitute its liquidity. The instant that such water is agitated, one portion of the liquid seizes upon the quantity of caloric in which it is deficient, at the expense of another portion, which of course becomes ice. Thus when water is cooled down to 22°, every particle of it wants 10° of the caloric necessary to keep it in a state of liquidity. Thirteen parts of it seize 10 degrees each from the fourteenth part. These thirteen of course acquire the temperature of 32°; and the other part, being deprived of $10 \times 13 = 130$, which with the ten degrees that it had lost before constitute 140°, or the whole of the caloric necessary to keep it fluid, assumes of consequence the form of ice.

Fourth. If these experiments should not be considered as sufficient to warrant Dr. Black's conclusion, the following, for which we are indebted to the same philosopher, puts the truth of his own opinion beyond the reach of dispute. He mixed together given weights of ice at 32°, and water at 190° of temperature. The ice was melted in a few seconds, and the temperature produced was 53°.

The weight of the ice was 119 half-drachms;
That of the hot water 135
of the mixture 254
of the glass vessel 16

Sixteen parts of glass have the same effect in heating cold bodies, as eight parts of equally hot water. Therefore, instead of the 16 half-drachms of glass, eight of water may be substituted, which makes the hot water amount to 143 half-drachms.

In this experiment there were 158 degrees of heat contained in the hot water, to be divided between the ice and the water. Had they been divided equally, and had the whole been afterwards sensible to the thermometer, the

water would have retained $\frac{143}{262}$ parts of this heat, and the ice would have received $\frac{119}{262}$ parts: that is to say, the water would have retained 86°, and the ice would have received 72°; and the temperature after mixture would have been 104°. But the temperature by experiment is found to be only 53°; the hot water lost 137°, and the ice only received an addition of temperature equal to 21°. But the loss of 18° of temperature in the water is equivalent to the gain of 21° in the ice. Therefore 158°—18° = 140° of heat have disappeared altogether from the hot water. These 140° must have entered into the ice, and converted it into water without raising its temperature.

In the same manner, if we take any quantity of ice, or, which is the same thing, snow at 32°, and mix it with an equal weight of water at 172°, the snow instantly melts, and the temperature of the mixture is only 32°. Here the water is cooled 140°, while the temperature of the snow is not increased at all; so that 140° of caloric have disappeared. They must have combined with the snow; but they have only melted it, without increasing its temperature. Hence it follows irresistibly, that ice, when it is converted into water, absorbs and combines with 140° of caloric.

Water, then, after being cooled down to 32°, cannot freeze till it has parted with 140° of caloric; and ice, after being heated to 32°, cannot melt till it has absorbed 140° of caloric. This is the cause of the extreme slowness of these operations. With regard to water, then, there can be no doubt that it owes its fluidity to the caloric which it contains, and that the caloric necessary to give fluidity to ice is equal to 140°.

To the quantity of caloric which thus occasions the fluidity of solid bodies by combining with them, Dr. Black gave the name of latent heat, because its presence is not indicated by the thermometer; a term sufficiently expressive, but other philosophers have rather chosen to call it caloric of fluidity.

Dr. Black and his friends ascertained also, by experiment, that the fluidity of melted wax, tallow, spermaceti, and metals, is owing to the same cause. Landriani proved, that this is the case with sulphur, alum, nitric, and several of the metals; and it has been found to be the case with every substance hitherto examined. We may consider it therefore as a general law, that whenever a solid is converted into a fluid, it combines with caloric, and that this is the cause of its fluidity.

From the experiments of Dr. Irvine, it appears that the caloric of fluidity of spermaceti is 145°

Bees-wax	175
Tin	500.

These are the only substances in which the quantity of caloric, absorbed during fusion, has been ascertained. In all of them we see this rule to hold, that the caloric of fluidity increases with the temperature at which liquidity takes place.

Dr. Black has rendered it exceedingly probable also, or rather he has proved by his experiments and observations, that the softness of such bodies as are rendered plastic by heat, depends upon a quantity of latent heat which combines with them. Metals also owe their malleability and ductility to the same cause. Hence the reason why they become hot and brittle when hammered.

II. Thus it appears, that the conversion of solids into liquids, is occasioned by the combination of a dose of caloric with the solid. But there is another change of state still more remarkable, to which bodies are liable when exposed to the action of heat. Almost all liquids, when raised to a certain temperature, gradually assume the form of an elastic fluid, invisible like air, and possessed of the same mechanical properties. Thus water, by boiling, is converted into steam, an invisible fluid, 1800 times more bulky than water, and as elastic as air. These fluids retain their elastic form as long as their temperature remains sufficiently high; but when cooled down again, they lose that form, and are convented into liquids. All liquids, and even a considerable number of solids, are capable of undergoing this change when sufficiently heated.

With respect to the temperatures at which liquids undergo this change, they may be all arranged under two divisions. There are some liquids which are gradually converted into elastic fluids at every temperature, while others again never begin to assume that change till their temperature reaches a certain point. Water is a well-known example of the first class of bodies. If an open vessel, filled with water, is carefully examined, we find that the water diminishes in bulk day after day, and at last disappears altogether. If the experiment is made in a vessel sufficiently large, and previously exhausted of air, we shall find that the water will fill the vessel in the state of invisible vapour, in whatever temperature it is placed. Alcohol likewise, and ether, and volatile oils, gradually assume the form of an elastic fluid in all temperatures. But sulphuric acid and the fixed oils never begin to assume the form of vapour till they are raised to a certain temperature. Though left in open vessels they lose no perceptible weight; neither does sulphuric acid lose any weight, though kept ever so long in the temperature of boiling water. When liquids gradually assume the form of elastic fluids in all temperatures, they are said to evaporate spontaneously. The second class of liquids want that property altogether.

When all other circumstances are the same, the evaporation of liquids increases with their temperature; and after they are heated to a certain temperature, they assume the form of elastic fluids with great rapidity. If the heat is applied to the bottom of the vessel containing the liquids, as is usually the case, after the whole liquid has acquired this temperature, those particles of it which are next the bottom become an elastic fluid first: they rise up, as they are formed, through the liquid, like air-bubbles, and throw the whole into violent agitation. The liquid is then said to boil. Every particular liquid has a fixed point at which this boiling commences (other things being the same), and this is called the boiling point of the liquid. Thus water begins to boil when raised to 212°. It is remarkable, that after a liquid has begun to boil, it never becomes any hotter, however strong the fire to which it is exposed. A strong heat indeed makes it boil more rapidly, but does not increase its temperature. This was first observed by Dr. Hooke. See Boiling.

It was observed, when treating of the melting point of solids, that it is capable of being varied considerably by altering the situation of the body. Thus water may be cooled down considerably lower than 32°, without freezing. The boiling point is still less fixed, depending en-

tirely on the degree of pressure to which the liquid to be boiled is exposed. If we diminish the pressure, the liquid boils at a lower temperature; if we increase it, a higher temperature is necessary to produce ebullition. From the experiments of professor Robinson, it appears that, in a vacuum, all liquids boil about 145° lower than in the open air under a pressure of 30 inches of mercury; therefore water would boil in vacuo at 67°, and alcohol at 34°. In a Papin's digester, the temperature of water may be raised to 300°, or even 400°, without ebullition: but the instant that this great pressure is removed, the boiling commences with prodigious violence.

The elasticity of all the elastic fluids into which liquids are converted by heat, increases with the temperature; and the vapour formed, when the liquid boils in the open air, possesses an elasticity just equal to that of air, or capable at a medium of balancing a column of mercury 30 inches high. The following very important table, drawn up by Mr. Dalton from his own experiments, exhibits the elasticity of steam, or the vapour of water of every temperature, from —40° to 325°. The elasticities of all the temperatures from 32° to 212° were ascertained by experiment; the rest were calculated by observing the rate at which the elasticity increased or diminished according to the temperature.

TABLE OF THE ELASTICITY OF STEAM.

Mr. Dalton has discovered that the elasticity of every other vapour or steam is precisely the same, with that of the steam of water at the same distance from its boiling point. Thus water boils at 212°; its elasticity at the temperature of 182°, or 30 under its boiling point, we see from the table is 15.86. Alcohol boils at 176°; the elasticity of the steam of alcohol at 146°, or 30° under its boiling point, is likewise 15.86. This very important discovery enables us to ascertain the elasticity of the vapours of all liquids whatever at any temperature, provided their boiling points are known. We have only to find how many degrees the temperature at which the elasticity required is distant from the boiling point of this liquid. The same number of degrees, added to or subtracted from 212°, gives us a temperature, opposite to which in the above table we shall find the elasticity required.

Such are the phenomena of the conversion of liquid into elastic fluids. Dr. Black applied his theory of latent heat to this conversion with great sagacity; and demonstrated, that it is owing to the very same cause as the conversion of solids into liquids; namely, to the combination of a certain dose of caloric with the liquid, without any increase of temperature. The truth of this very important point was established by the following experiments.

First. When a vessel of water is put upon the fire, the water gradually becomes hotter till it reaches 212°; but afterwards its temperature is not increased. Now caloric must be constantly entering from the fire and combining with the water. But as the water does not become hotter, the caloric must combine with that part of it which flies off in the form of steam; but the temperature of the steam is only 212°; therefore the caloric combined with it does not increase its temperature. We must conclude, then, that the change of water to steam is owing to the combination of this caloric; for it produces no other change.

Dr. Black put some water in a tin-plate vessel upon a red-hot iron. The water was of the temperature of 50°; in four minutes it began to boil, and in 20 minutes it was all boiled off. During the first four minutes it had received 162°, or $40\frac{1}{2}$ per minute. If we suppose that it received as much per minute during the whole process of boiling, the caloric which entered into the water and converted it into steam would amount to $40\frac{1}{2} \times 20 =$ 810°. This caloric is not indicated by the thermometer, for the temperature of steam is only 212°; therefore Dr. Black called it latent heat.

Second. Water may be heated in a Papin's digester to 400° without boiling; because the steam is forcibly compressed, and prevented from making its escape. If the mouth of the vessel is suddenly opened while things are in this state, part of the water rushes out in the form of steam, but the greater part still remains in the form of water, and its temperature instantly sinks to 212°; consequently 188° of caloric have suddenly disappeared. This caloric must have been carried off by the steam. Now as only about 1-5th of the water is converted into steam, that steam must contain not only its own 188°, but also the 188° lost by each of the other four parts; that is, it must contain 188° × 5, or about 940°. Steam therefore is water combined with at least 940° of caloric, the presence of which is not indicated by the thermometer. This experiment was first made by Dr. Black, and afterwards with more precision by Mr. Watt.

Third. When hot liquids are put under the receiver of an air-pump, and the air is suddenly drawn off, the liquids boil, and their temperature sinks with great rapidity a considerable number of degrees. Thus water, however hot at first, is very soon reduced to the temperature of 70°, and ether becomes suddenly so cold, that it freezes water placed round the vessel which contains it. In these cases the vapour undoubtedly carries off the heat of the liquid: but the temperature of the vapour is never greater than that of the liquid itself; the heat therefore must combine with the vapour, and become latent.

Fourth. If one part of steam at 212° is mixed with nine parts by weight of water at 62°, the steam instantly assumes the form of water, and the temperature after mixture is 178.6°, consequently each of the nine parts of water has received 116.6° of caloric; of course the steam has lost 9 × 116.6° = 1049.4° of caloric. But as the temperature of the steam is diminished by 33.3°, we must subtract this sum. There will remain rather more than 1000°, which is the quantity of caloric which existed in the steam without increasing its temperature. This experiment cannot be made directly; but it may be made by passing a given weight of steam through a metallic worm, surrounded by a given weight of water. The heat acquired by the water indicates the caloric which the steam gives out during its condensation. From the experiments of Mr. Watt made in this manner, it appears that the latent heat of steam amounts to 940°. The experiments of M. Lavoisier make it rather more than 1000°.

By the experiments of Dr. Black and his friends, it was ascertained, that not only water, but all other liquids during their conversion into vapour, combine with a dose of caloric, without any change of temperature; and that every kind of elastic fluid, during its conversion into a liquid, gives out a portion of caloric without

any change of temperature. Dr. Black's law is then very general, and comprehends every change in the state of a body. The cause of the conversion of a solid into a liquid is the combination of the solid with caloric; that of the conversion of a liquid into an elastic fluid is the combination of the liquid with caloric. Liquids are solids combined with caloric; elastic fluids are liquids combined with caloric. This law, in its most general form, may be stated as follows: whenever a body changes its state, it either combines with caloric, or separates from caloric.

No person will dispute that this is one of the most important discoveries hitherto made in philosophy. Science is indebted for it entirely to the sagacity of Dr. Black. Other philosophers indeed have laid claim to it; but these claims are either without any foundation, or their notions may be traced to Dr. Black's lectures, as their opinions originated many years posterior to the public explanation of Dr. Black's theory in the chemical chairs of Glasgow and Edinburgh.

III. A very considerable number of bodies, both solids and liquids, may be converted into elastic fluids by heat; and as long as the temperature continues sufficiently high, they retain all the mechanical properties of gaseous bodies. It is exceedingly probable, that if we could command a heat sufficiently intense, the same change might be produced on all bodies in nature. This accordingly is the opinion at present admitted by philosophers. But if all bodies are convertible into elastic fluids by heat, it is exceedingly probable that all elastic fluids in their turn might be converted into solids or liquids, if we could expose them to a sufficiently low temperature. In that case, all the gases must be supposed to owe their elasticity to a certain dose of caloric: they must be considered as compounds of caloric with a solid or liquid body. This opinion was first stated by Amontons, and it was supported with much ingenuity both by Dr. Black and Lavoisier, and his associates. It is at present the prevailing opinion; and it is certainly supported not only by analogy, but by several very striking facts.

If its truth is admitted, we must consider all the gases as capable of losing their elasticity by depriving them of their heat: they differ merely from the vapours in the great cold which is necessary to produce this change. Now the fact is, that several of the gases may be condensed into liquids by lowering their temperatures. Oxymuriatic acid gas becomes liquid at a temperature not much under 40°; and at 32° it even forms solid crystals. Ammoniacal gas condenses into a liquid at — 45°. None of the other gases have been hitherto condensed.

It is well known, that the condensation of vapours is greatly assisted by pressure; but the effect of pressure diminishes as the temperature of vapours increases. It is very likely that pressure would also contribute to assist the condensation of gases. It has been tried without effect indeed in several of them. Thus air has been condensed till it was heavier than water; yet it showed no disposition to lose its elasticity. But this may be ascribed to the high temperature at which the experiment was made relative to the point at which air would lose its elasticity.

At the same time it cannot be denied, that there are several phenomena scarcely reconcilable to this constitution of the gases, ingenious and plausible as it is. One of the most striking is the sudden solidification which ensues when certain gases are mixed together. Thus when ammoniacal gas and muriatic acid gas are mixed, the product is a solid salt; yet the heat evolved is very inconsiderable, if we compare it with the difficulty of condensing these gases separately, and the great cold which they endure before losing their elasticity. In other cases too, gaseous bodies unite, and form a new gas, which retains its elasticity as powerfully as ever. Thus oxygen gas and nitrous gas combined form a new gas, namely, nitric acid, which is permanent till it comes into contact with some body on which it can act.

FLUOR-ALBUS. See MEDICINE.

FLUOR-SPAR. See FLUAT of LIME.

The principal use of fluats is for smelting ores, where they act as very powerful fluxes, and on this account are much valued. They are found in various countries, particularly Sweden, and some other northern countries of Europe. From this quality of melting easily in combination with other earthy matters, they have got the name of fluors. "The resemblance between the coloured fluors and the composition made of coloured glass (says Cronstedt), has perhaps contributed not only to the fluors being reckoned of the same value with the coloured quartz crystals, by such collectors as only mind colour and figure, but to their also obtaining a rank among the precious stones in the apothecaries' and druggists' shops." Mr. Fabroni observes, that the combination of calcareous earth with the sparry acid is almost always transparent: it often crystallizes in regular cubes, sometimes single from one line to two inches in diameter, and sometimes of an indeterminate figure. They are sometimes of a blue colour; others are purple like amethysts; some are of a brown colour, others opaque. M. Magellan says, that fluors in general have this singular property, that on being melted by the flame of the blow-pipe, together with gypsum, the product resulting from both is all formed with facets on the outside; but if melted with terra ponde rosa, its surface is quite round or spherical.

FLUORIC ACID. The mineral called fluor, or fusible spar, and in this country Derbyshire spar, was not properly distinguished from other spars till Margraff published a dissertation on it in the Berlin Transactions for 1768. He first proved, that it contained no sulphuric acid, as had been formerly supposed: he then attempted to decompose it, by mixing together equal quantities of this mineral and sulphuric acid, and distilling them. By this method he obtained a white sublimate, which he supposed to be the fluor itself volatilized by the acid. He observed with astonishment, that the glass retort was corroded, and even pierced with holes. Nothing more was known concerning fluor till Scheele published his experiments three years after, by which he proved that it is composed chiefly of lime and a particular acid, which has been called fluoric acid.

The composition of fluoric acid is equally unknown with that of muriatic acid. Mr. Henry tried in vain to decompose it by means of electricity. It is always obtained from fluor spar, in which mineral it is found in abundance. For the investigation of the properties of this acid, we are indebted chiefly to Scheele and Priestly.

1. It may be obtained by putting a quantity of the spar in powder into a retort, pouring over it an equal

quantity of sulphuric acid, and then applying a very gentle heat. A gas issues from the beak of the retort, which may be received in the usual manner in glass jars standing over mercury. This gas is fluoric acid.

The acid may be obtained dissolved in water by luting to the retort a receiver containing water. The distillation is to be conducted with a very moderate heat, not only to allow the gas to condense, but also to prevent the fluor itself from subliming. After the process, provided a glass retort has been employed, a crust of white earth is found in the receiver, which has all the properties of silica.

Scheele supposed that the silica produced was formed of fluoric acid and water; and Bergman adopted the same opinion. But Wiegleb and Buccholz showed that the quantity of silica was exactly equal to what the retort lost in weight; and Meyer completed the proof that it was derived from the glass, by the following experiment. He put into each of three equal cylindrical tin vessels a mixture of three ounces of sulphuric acid and one ounce of fluor, which had been pulverized in a mortar of metal. Into the first he put one ounce of pounded glass; into the second the same quantity of quartz in powder; and into the third nothing. Above each of the vessels he hung a spunge moistened with water, and having covered them, he exposed them to a moderate heat. The sponge in the first cylinder was covered with the crust in half an hour; the sponge in the second in two hours; but no crust was formed in the third, though it was exposed several days. In consequence of this decisive experiment, Bergman gave up his opinion; and wrote an account of Meyer's experiment to Morveau, who was employed in translating his works, to enable him to correct the mistake in his notes.

Soon after the discovery of this acid, difficulties and doubts concerning its existence as a peculiar acid were started by some French chemists. To remove these objections, Mr. Scheele instituted and published a new set of experiments; which not only completely established the peculiar nature of the fluoric acid, but once more displayed the unrivalled abilities of the illustrious discoverer. It would be needless to enumerate these objections, as they originated entirely from want of precision, and did not produce a single convert.

2. Fluoric acid gas is invisible and elastic like air; it does not maintain combustion, nor can animals breathe it without death. It has a pungent smell, not unlike that of muriatic acid. It is heavier than common air. It corrodes the skin almost instantly.

3. Neither caloric nor light produces any alteration on it.

4. When water is admitted in contact with this gas, it absorbs it rapidly; and if the gas has been obtained by means of glass vessels, it deposits at the same time a quantity of silica.

Water absorbs a considerable proportion of this gas, but the precise quantity has not been determined. The compound is usually termed fluoric acid by chemists. It is specifically heavier than water, has an acid taste, reddens vegetable blues, and does not freeze till cooled down to 23°. When heated, the acid gas is easily expelled, except the last portions of it, which adhere with great obstinacy.

5. Neither oxygen gas nor any of the simple combustibles or incombustibles produce any change on fluoric acid, either in the gaseous or liquid state.

6. Fluoric acid gas does not act upon any of the metals, but liquid fluoric acid is capable of oxidizing iron, zinc, copper, and arsenic. It does not act upon gold, platinum, silver, mercury, lead, tin, antimony, cobalt.

7. It combines with alkalies, earths, and metallic oxides, and forms with them salts which are denominated fluats. See FLUAT.

The most singular property of fluoric acid is the facility with which it corrodes glass and siliceous bodies, especially when hot, and the ease with which it holds silica in solution even when in the state of gas. This affinity for silica is so great, that the thickest glass vessels can only withstand its action for a short time; and the greatest precautions are scarcely sufficient to obtain it entirely free from siliceous earth.

8. It produces no change, as far as is known, upon any of the acids already described.

9. Its affinities are as follows:

Lime,
Barytes,
Strontian,
Magnesia,
Potass,
Soda,
Ammonia,
Glucina,
Alumina,
Zirconia,
Silica.

10. As fluoric acid produces an insoluble compound with lime, it may be employed with great advantage, as Pelletier has observed, to detect the presence of that earth when held in solution. A drop or two of the acid causes a milky cloud or precipitate to appear, if any lime is present. The property which this acid has of corroding glass, has induced several ingenious men to attempt, by means of it, to engrave, or rather etch, upon glass. The glass is covered completely with wax; and then that part where the letters or figures are to appear is laid bare, by removing the wax. The whole is then exposed for some time to the hot vapours of fluoric acid. This simple process is employed with advantage in writing labels on glass vessels, and in graduating thermometers, and other similar instruments. The discovery is by no means new; it has been shewn by Beckman and Accum, that this acid was employed for that purpose by Henry Swanhard, an artist of Nuremberg, as early as 1670. He seems to have kept his art for some time secret, but the receipt was made public by Pauli in 1725. See ETCHING ON GLASS.

FLUSTRA, a genus of insects of the order zoophyta; an animal of the polypus kind, proceeding from porous shells; stem fixed, foliaceous, membranaceous, consisting of numerous rows of cells united together, and woven like a mat. There are many species. The verticillata is found in the Mediterranean, adhering to fuci: the cells, when magnified, appear surrounded by sharp denticles, with a long bristle in the front of each, bending inwards like a horn; the mouths incline forwards, and their whole substance appears full of small points.

FLUTE, *fistula*, an instrument of music, the simplest of all those of the wind kind. It is played on by blowing it with the mouth, and the tones or notes are changed by stopping and opening the holes disposed for that purpose along its side. The ancient fistulæ, or flutes, were made of rods, afterwards of wood, and last of metal; but how they were blown, whether as our flutes, or as hautboys, does not appear.

Flute, *German*, is an instrument entirely different from the common flute. It is not, like that, put into the mouth to be played, but the end is topt with a tampion, or plug, and the lower lip is applied to a hole about two inches and a half, or three inches, distant from the end. This instrument is usually about a foot and a half long, rather larger at the upper end than the lower, and perforated with holes, besides that for the mouth, the lowest of which is stopt and opened by the little finger's pressing on a brass, or sometimes a silver key, like those in hautboys, bassoons, &c. It is found exceeding sweet and agreeable, and serves as a treble in a concert.

Flute, or Fluyt, (originally perhaps float) is a kind of long vessel, with flat ribs, or floor timbers; round behind, and swelled in the middle; serving chiefly for the carrying of provisions in fleets, or squadrons of ships, though it is also used for merchandize.

Flutes, or Flutings, in architecture, perpendicular channels, or cavities, cut along the shaft of a column, or pilaster. See Architecture.

FLUX, in medicine, an extraordinary issue, or evacuation, of some humours of the body. See Medicine.

Flux, in metallurgy, is sometimes used synonymously with fusion: for instance, an ore, or rather matter, is said to be in liquid flux, when it is completely fused. But the word flux is generally used to signify certain saline matters, which facilitate the fusion of ores, and other substances which are difficultly fusible in assays, and in the reductions of ores. We shall here describe the fluxes recommended by Bergman, in vol. ii.

1. The phosphoric acid, or rather the microcosmic salt, as it is called, which contains that acid partly saturated with mineral, partly with ammonia, and loaded besides with much water. This salt, when exposed to the flame, boils and foams violently, with a continual crackling noise, until the water and ammonia have flown off; afterwards it is less agitated, sending forth something like black scoriæ arising from the burned gelatinous part: these, however, are soon dispelled, and exhibit a pellucid sphericle encompassed by a beautiful green cloud, which is occasioned by the deflagration of the phosphorus, arising from the extrication of the acid by means of the inflammable matter. The clear globule which remains, upon the removal of the flame, continues longer soft than that formed by borax, and therefore is more fit for the addition of the matter to be dissolved. The ammonia is expelled by the fire; therefore an excess of acid remains in what is left behind, which readily attracts moisture in a cool place. 2. Soda, when put upon charcoal, melts superficially, penetrates the charcoal with a crackling noise, and then disappears. In the spoon it yields a permanent and pullucid sphericle, as long as it is kept fluid by the blue apex of the flame; but when the heat is diminished, it becomes opaque, and assumes a milky colour. It attacks several earthy matters, particularly those of the siliceous kind, but cannot be employed on charcoal. 3. Crystallized borax, exposed to the flame urged by the blow-pipe or charcoal, first becomes opaque, white, and excessively swelled, with various protuberances, or branches proceeding out from it. When the water is expelled, it easily collects itself into a mass, which, when well fused, yields a transparent sphericle, retaining its transparency even after cooling. If calcined borax is employed, the clear sphericle is obtained the sooner.

Having provided every thing necessary, the following directions are next to be attended to. 1. A common tallow candle, not too thick, is generally preferable to a wax candle, or to a lamp. The snuff must not be cut too short, as the wick should bend towards the object. 2. The weaker exterior flame must first be directed upon the object, until its effects are discovered; after which the interior flame must be applied. 3. We must observe with attention whether the matter decrepitates, splits, swells, vegetates, boils, &c. 4. The piece exposed to the flame should scarcely ever exceed the size of a peppercorn, but ought always to be large enough to be taken up by the forceps. 5. A small piece should be added separately to each of the fluxes; concerning which it must be observed whether it dissolves wholly or only in part; whether this is effected with or without effervescence, quickly or slowly; whether the mass is divided into a powder, or gradually and externally corroded; with what colour the glass is tinged, and whether it becomes opaque, or remains pellucid.

Having given these directions, Mr. Bergman proceeds next to consider the subjects proper to be examined by the blowpipe. These he divides into four classes: 1. Saline; 2. Earthy; 3. Inflammable; and 4. Metallic. As the subject, however, is treated at considerable length, we shall refer the reader to Mr. Bergman's writings, and confine ourselves in this place to what he has advanced concerning the last of these subjects, namely, metallic substances.

The perfect metals, when calcined (oxygenated) in the moist way, recover their former nature by simple fusion. The imperfect metals are calcined by fire, especially by the exterior flame; and then, in order to their being reduced, indispensably require the contact of an inflammable substance. With respect to fusibility, the two extremes are mercury and platina; the former being scarcely ever seen in a solid form, and the latter almost as difficult of fusion. The metals, therefore, may be ranked in this order, according to their degrees of fusibility. 1. Mercury; 2. Tin; 3. Bismuth; 4. Lead; 5. Zinc; 6. Antimony; 7. Silver; 8. Gold; 9. Arsenic; 10. Cobalt; 11. Nickel; 12. Iron; 13. Manganese; 14. Platinum. The last two do not yield to the blowpipe, and indeed forged iron does not melt without difficulty; but cast iron perfectly.

Metals in fusion affect a globular form, and easily roll off the charcoal, especially when of the size of a grain of pepper. Either smaller pieces, therefore, ought to be used, or they should rest in hollows made in the charcoal. On their first melting they assume a polished surface, an appearance always retained by the perfect metals; but the imperfect are soon obscured by a pellicle formed of the calx (oxide) of the metal. The colours

communicated by the calces vary, according to the nature of the metal from which the calx is produced. Some of the calces easily recover their metallic form by simple exposure to flame upon the charcoal; others are reduced in this way with more difficulty; and some not at all. The reduced calces of the volatile metals immediately fly off from the charcoal. In the spoon they exhibit globules; but it is very difficult to prevent them from being first dissipated by the blast.

The metals are taken up by the fluxes; but as soda yields an opaque spherule, it is not to be made use of. Globules of borax dissolve and melt any metallic calx; and, unless too much loaded with it, appear pellucid and coloured. A piece of metal calcined in flux produces the same effect, but more slowly. A portion of the calx generally recovers its metallic form, and floats on the melted matter like one or more excrescences.

The calces of the perfect metals are reduced by borax in the spoon, and adhere to it at the point of contact, and there only. The microcosmic salt acts like borax, but does not reduce the metals. It attacks them more powerfully on account of its acid nature; at the same time it preserves the spherical form, and therefore is adapted in a peculiar manner to the investigation of metals.

The tinge communicated to the flux frequently varies, being different in the fused and in the cooled globule; for some of the dissolved calces, while fused, show no colour, but acquire one while cooling; but others, on the contrary, have a much more intense colour while in the state of fluidity. Should the transparency be injured by too great a concentration of colour, the globule, on compressing it with the forceps, or drawing it out into a thread, will exhibit a thin and transparent mass; but if the opacity arises from supersaturation, more flux must be added; and as the fluxes attract the metals with unequal forces, the latter precipitate one another.

Metals when mineralized by acids have the properties of metallic salts; when mineralized by carbonic acid, they possess the properties of calces, that volatile substance being easily expelled without any effervescence; but when combined with sulphur they possess properties of a peculiar kind. They may then be melted, or even calcined upon the charcoal, as also in a golden or silver spoon. The volatile parts are distinguished by the smell or smoke; the fixed residua, by the particles reduced or precipitated upon iron, or from the tinge of the fluxes.

Gold in its metallic state fuses on the charcoal, and is the only metal which remains unchanged. It may be oxygenated in the moist way by solution in aqua regia; but to calcine it also by fire, we must pursue the following method: To a globule of microcosmic salt, let there be added a small piece of solid gold, of gold leaf, purple mineral, or, which is best of all, of the crystalline salt formed by a solution of gold in aqua regia containing sea-salt. Let this again be melted, and added while yet soft to turbith mineral, which will immediately grow red on the contact. The fusion being afterwards repeated, a vehement effervescence arises; and when this is considerably diminished, let the blast be stopped for a few moments, again begun, and so continued until almost all the bubbles disappear. After this the spherule, on cooling, assumes a ruby colour; but if this does not happen, let it be just made soft by the exterior flame, and upon hardening, this tinge generally appears. Should the process fail at first, owing to some minute circumstances which cannot be described. it will succeed on the second or third trial. The ruby-coloured globule, when compressed by the forceps while hot, frequently becomes blue; by sudden fusion it generally assumes an opal colour, which by refraction appears blue, and by reflection of a brown red. If further urged by the fire it loses all colour, and appears like water; but the redness may be reprod ced several times by the addition of turbith mineral. The flux is reddened in the same manner by the addition of tin instead of turbith; but it has a yellowish hue, and more easily becomes opaque; while the redness communicated by turbith mineral has a purple tinge, and quite resembles a ruby. Borax produces the same phenomena, but more rarely; and in all cases the slightest variation in the management of the fire will make the experiment fail entirely.

The ruby colour may also be produced by copper; whence a doubt may arise, whether it is the gold or the remains of the copper that produce this effect. Mr. Bergman thinks it probable that both may contribute towards it, especially as copper is often found to contain gold.

This precious metal cannot directly be mineralized by sulphur; but by the medium of iron is sometimes formed into a golden pyrites. Here, however, the quantity of gold is so small, that a globule cannot scarcely be extracted from it by the blowpipe.

Grains of native platinum are not affected by the blowpipe, either alone or mixed with fluxes; which, however, are frequently tinged green by it: but platinum, precipitated from aqua regia by vegetable or volatile alkali, is reduced by microcosmic salt to a small malleable globule. Our author has been able to unite seven or eight of these into a malleable mass; but more of them produced only a brittle one. Platinum scarcely loses all its iron, unless reduced to very thin fusion.

Silver in its metallic state easily melts, and resists calcination. Silver leaf fastened by means of the breath, or a solution of borax, may easily be fixed on it by the flame, and through the glass it appears of a gold colour; but care must be taken not to crack the glass. Calcined silver precipitated from nitrous acid by fixed alkali is easily reduced. The microscomic acid dissolves it speedily and copiously; but on cooling it becomes opaque, and of a whitish yellow, which is also sometimes the case with leaf-silver. Copper is discovered by a green colour, and sometimes by that of a ruby, unless we choose rather to impute that to gold. The globules can scarcely be obtained pellucid, unless the quantity of calx is very small; but a longer fusion is necessary to produce an opacity with borax. The globule, loaded with dissolved silver during the time of its fusion in the spoon, covers a piece of copper with silver, and becomes itself of a pellucid green: antimony quickly takes away the milky opacity of dissolved luna cornea, and separates the silver in distinct grains. Cobalt, and most of the other metals likewise, precipitate silver on the same principles as in the moist way, viz. by a double elective attraction. This metal, when mineralized by marine and vitriolic acids, yields a natural luna cornea, which produces a number of small metallic globules on the charcoal: it dissolves in

microcosmic salt, and renders it opaque, and is reduced, partially at least, by borax. Sulphurated silver, called also the glassy ore of that metal, fused upon charcoal, easily parts with the sulphur it contains; so that a polished globule is often produced, which, if necessary, may be depurated by borax. The silver may also be precipitated by the addition of copper, iron, or manganese. When arsenic makes part of the compound, as in the red ore of arsenic, it must first be freed from the sulphur by gentle roasting, and finally entirely depurated by borax. It decrepitates in the fire at first.

Copper, together with sulphur and arsenic mixed with silver, called the white ore of silver, yields a regulus having the same alloy.

Galena, which is an ore of lead containing sulphur and silver, is to be freed in the same manner from the sulphur; after which the lead is gradually dissipated by alternately melting and cooling, or is separated in a cupel from the galena by means of the flame. Bergman has not been able to precipitate the silver distinct from the lead, but the whole mass becomes malleable; and the same is true of tin, but the mass becomes more brittle.

Pure mercury flies off from the charcoal with a moderate heat, the fixed heterogeneous matters remaining behind. When calcined, it is easily reduced and dissipated, and the fluxes take it up with effervescence; but it is soon totally driven off. When mineralized by sulphur, it liquefies upon the charcoal, burns with a blue flame, smokes, and gradually disappears; but, on exposing cinnabar to the fire on a polished piece of copper, the mercurial globules are fixed upon it all round.

Lead in its metallic state readily melts, and continues to retain a metallic splendour for some time. By a more intense heat it boils and smokes, forming a yellow circle upon the charcoal. It communicates a yellow colour, scarcely visible, to the fluxes; and when the quantity is large, the globule, on cooling, contracts more or less of a white opacity. It is not precipitated by copper when dissòlved; nor do the metals precipitate it from sulphur in the same order as from the acids. When united to carbonic acid, it grows red on the first touch of the flame; when the heat is increased it melts, and is reduced to a multitude of small globules. When united with phosphoric acid it melts, and yields an opaque globule, but is not reduced. With fluxes it shows the same appearances as oxide of lead. When mineralized by sulphur, lead easily liquefies, and being gradually deprived of the volatile part, yields a distinct regulus, unless too much loaded with iron. It may be precipitated by iron and copper.

A small piece of copper, either solid or foliated, sometimes communicates a ruby colour to fluxes, especially when assisted by tin or turbith mineral. If the copper is a little more or further calcined, it produces a green pellucid globule, the tinge of which grows weaker by cooling, and even verges towards a blue. By long fusion with borax, the colour is totally destroyed upon charcoal, but scarcely in the spoon. When once destroyed, this colour can scarcely be reproduced by nitre; but it remains fixed with microcosmic salt. If the calx or metal to be calcined is added in considerable quantity during fusion, it acquires an opaque red on cooling, though it appears green while pellucid and fused; but by a still larger quantity it contracts an opacity even while in fusion, and upon cooling a metallic splendour. Even when the quantity of copper is so small as scarcely to tinge the flux, a visible pellicle is precipitated upon a piece of polished iron added to it during strong fusion, and the globule in its turn takes the colour of polished iron; and in this way the smallest portions of copper may be discovered. The globule made green by copper, when fused in the spoon with a small portion of tin, yields a spherule of the latter mixed with copper, very hard and brittle: in this case the precipitated metal pervades the whole of the mass, and does not adhere to the surface. Cobalt precipitates the calx of copper dissolved in the spoon by a flux, in a metallic form, and imparts its own colour to glass, which nickel cannot do. Zinc also precipitates it separately, and rarely upon its own surface, as we can scarcely avoid melting it. When mineralized by the carbonic acid, copper grows black on the first contact of the flame, and melts in the spoon; on the charcoal the lower part, which touches the support, is reduced. With a superabundance of marine acid, it tinges the flame of a beautiful colour: but with a small quantity shows no appearance of the metal in that way. Thus the beautiful crystals of Saxony, which are cubic, and of a deep green, do not tinge the flame, though they impart a pellucid greenness to microcosmic salt. An opaque redness is easily obtained with borax: but Mr. Bergman could not produce this colour with microcosmic salt. Copper simply sulphurated, when cautiously and gently roasted by the exterior flame, yields at last by fusion a regulus surrounded with a sulphurated crust. The mass roasted with borax separates the regulus more quickly.

If a small quantity of iron happens to be present, the piece to be examined must first be roasted, after which it must be dissolved in borax, and tin added to precipitate the copper. The regulus may also be obtained by sufficient calcination and fusion, even without any precipitant, unless the ore is very poor. When the pyrites contain copper, even in the quantity of the one-hundredth part of their weight, its presence may be detected by these experiments. Let a grain of pyrites, of the size of a flax-seed, be roasted, but not so much as to expel all the sulphur; let it then be dissolved by borax, a polished rod of iron added, and the fusion continued until the surface when cooled loses all splendour. As much borax is required as will make the whole of the size of a grain of hemp-seed. Slow fusion is injurious, and the precipitation is also retarded by too great tenuity; but this may be corrected by the addition of a little lime. Too much calcination is also inconvenient; for by this the globule forms slowly, is somewhat spread, becomes knotty when warm, corrodes the charcoal, destroys the iron, and the copper does not precipitate distinctly. This defect is corrected by a small portion of crude ore. When the globule is properly melted, according to the directions already given, it ought to be thrown into cold water immediately on stopping the blast, in order to break it suddenly. If the copper contained in it is less than one-hundredth part, one end of the wire only has a cupreous appearance, but otherwise the whole.

Dr. Gahn has another method of examining the ores of copper, namely, by exposing a grain of the ore, well freed from sulphur by calcination, to the action of the

flame driven suddenly upon it by intervals. At those instances a cupreous splendour appears on the surface, which otherwise is black; and this splendour is more quickly produced in proportion as the ore is poorer. The flame is tinged green by cupreous pyrites on roasting.

Forged iron is calcined, but can scarcely be melted. It cannot be melted by borax, though it may by microcosmic salt, and then it becomes brittle. Calcined iron becomes magnetic by being heated on the charcoal, but melts in the spoon. The fluxes become green by this metal; but in proportion as the oxygen is more abundant, they grow more of a brownish yellow. On cooling, the tinge is much weakened, and when originally weak, vanishes entirely. By too much saturation the globule becomes black and opaque. The sulphureous pyrites may be collected into a globule by fusion, and is first surrounded by a blue flame; but as the metal is easily calcined, and changes into black scoriæ, neither by itself nor with fluxes does it exhibit a regulus. It grows red on roasting.

Tin easily melts before the blowpipe, and is calcined. The fluxes dissolve the calx sparingly; and when saturated, contract a milky opacity. Some small particles of this metal dissolved in any flux may be distinctly precipitated upon iron. Crystallized ore of tin, urged by fire upon the charcoal, yields its metal in a reguline state.

Bismuth presents nearly the same appearances as lead; the calx is reduced on the coal, and fused in the spoon. The calx, dissolved in microcosmic salt, yields a brownish yellow globule, which grows more pale upon cooling, at the same time losing some of its transparency. Too much calx renders the matter perfectly opaque. Borax produces a similar mass in the spoon, but on the coal a grey one, which can scarcely be freed from bubbles. On fusion the glass smokes, and forms a cloud about it. Bismuth is easily precipitated by copper and iron. Sulphurated bismuth is easily fused, exhibiting a blue flame and sulphureous smell. Cabalt, when added, by means of sulphur, enters the globule; but the scoria soon swells into distinct partitions; which, when further urged by fire, throw out globules of bismuth. Sulphurated bismuth, by the addition of borax, may be distinctly precipitated by iron or manganese.

Regulus of nickel when melted is calcined, but more slowly than other metals. The calx imparts an hyacinthine colour to fluxes, which grows yellow on cooling, and by long continued fire may be destroyed. If the calx of nickel is contaminated by ochre of iron, the latter is first dissolved. Nickel dissolved is precipitated on iron, or even on copper; an evident proof that it does not originate from either of these metals. Sulphurated nickel is no where found without iron and arsenic: the regulus is obtained by roasting, and fusing with borax, though it still remains mixed with some other metals.

Regulus of arsenic takes fire by a sudden heat, and not only deposits a white smoke on charcoal, but diffuses the same all around. The calx smokes with a smell of garlic, but does not burn. The fluxes grow yellow, without growing opaque, on adding a proper quantity of calx, which is dispelled by a long continuance of the heat. This semimetal is precipitated in a metallic form by iron and copper, but not by gold. Yellow arsenic liquefies, smokes, and totally evaporates: when heated by the external flame, so as neither to liquefy nor smoke, it grows red, and yellow again upon cooling. When it only begins to melt, it acquires a red colour, which remains after cooling. Realgar liquefies more easily, and is besides totally dissipated.

Regulus of cobalt melts, and may partly be depurated by borax, as the iron is first calcined and taken up. The smallest portion of the calx tinges the flux of a deep-blue colour, which appears of a violet by refraction, and this colour is very fixed in the fire. Cobalt is precipitated upon iron from the blue globule, but not upon copper. When calx of iron is mixed with that of cobalt in a flux, the former is dissolved. This semimetal take up about one-third of its weight of sulphur in fusion, after which it can hardly be melted again. It is precipitated by iron, copper, and several other metals. The common ore yields an impure regulus by roasting. The green cobalt, examined by our author, tinges the microcosmic salt blue; but at the same time shows red spots, indicating copper.

Zinc exposed to the blowpipe melts, takes fire, sending forth a beautiful blueish-green flame, which however is soon extinguished by a lanuginous calx; but if the reguline nucleus included in this lanuginous matter (commonly called flowers of zinc) is urged by the flame, it will be now and then inflamed, and as it were, explode and fly about. With borax it froths, and at first tinges the flame. It continually diminishes, and the flux spreads upon the charcoal; but in used microcosmic salt, it not only froths, but sends forth flashes with a crackling noise. Too great heat makes it explode with the emission of ignited particles. The white calx, or flower, exposed to the flame on charcoal, becomes yellowish, and has a kind of splendour which vanishes when the flame ceases. It remains fixed, and cannot be melted. The fluxes are scarcely tinged, but when saturated by fusion, they grow opaque and white on cooling. Clouds are formed around the globules, of a nature similar to those of the metallic calx. Dissolved zinc is not precipitated by any other metal. When mineralized by carbonic acid gas, it has the same properties as calcined zinc. In the pseudo galena sulphur and iron are present. These generally, on the charcoal, smell of sulphur, melt, and tinge the flame more or less, depositing a cloud all around. Those which have no matrix are tinged by those which contain iron, and acquire by saturation a white opaque colour, verging to brown or black, according to the variety of composition.

Regulus of antimony, fused and ignited on the charcoal, affords a beautiful object; for if the blast of air be suddenly stopped, a thick white smoke rises perpendicularly, while the lower part round the globule is condensed into crystalline spiculæ, similar to those called argentine flowers. The calx tinges fluxes of an hyacinthine colour; but on fusion smokes, and is easily dissipated, especially on the charcoal, though it also deposits a cloud on it. The dissolved metal may be precipitated by iron and copper, but not by gold. Crude antimony liquefies on the charcoal, spreads, smokes, penetrates it, and at last disappears entirely, except a ring which it leaves behind.

Regulus of manganese scarcely yields to the flame. The black calx tinges the fluxes of a blueish colour; bo-

rax, unless saturated, communicates more of a yellow colour. The colour may be gradually dissolved altogether by the interior flame, and again reproduced by a small particle of nitre, or the exterior flame alone. Combined with carbonic acid, it is of a white colour, which changes by ignitition to black. In other respects it shows the same experiments as the black calx.

Fixed alkalis, nitre, borax, tartar, and common salt, are the saline matters of which fluxes are generally composed. But the word flux is more particularly applied to mixtures of different proportions of only nitre and tartar; and these fluxes are called by particular names, according to the proportions of these ingredients, as in the following instances.

Flux, *white*, is made with equal parts of nitre and of tartar detonated together, by which they are alkalised. The residuum of this detonation is an alkali composed of alkalis of the nitre and of the tartar, both which are absolutely of the same nature. As the proportion of nitre in this mixture is more than is sufficient to consume entirely all the inflammable matter of the tartar, the alkali remaining after the detonation is perfectly white, and is therefore called white flux; and as this alkali is made very quickly, it is also called extemporaneous alkali. When a small quantity only of white flux is made, as a few ounces for instance, some nitre always remains undecomposed, and a little of the acid of the tartar, which gives a red, or even a black colour, to some part of the flux; but this does not happen when a large quantity of white flux is made, because then the heat is much greater. The small quantity of undecomposed nitre and tartar which remains in white flux is not hurtful in most of the metallic fusions in which this flux is employed; but if the flux is required perfectly pure, it might easily be disengaged from those extraneous matters by a long and strong calcination, without fusion.

Flux, *crude*. By crude flux is meant the mixture of nitre and tartar in any proportions, without detonation. Thus the mixture of equal parts of the two salts used in the preparation of the white flux, or the mixture of one part of nitre and two parts of tartar for the preparation of the black flux, are each of them a crude flux before detonation. It has also been called white flux, from its colour; but this might occasion it to be confounded with the white flux above described. The name, therefore, of crude flux is more convenient. Crude flux is detonated and alkalised during the reductions and fusions in which it is employed; and is then changed into white or black flux, according to the proportions of which it is composed. This detonation produces good effects in these fusions and reductions, if the swelling and extravasation of the detonating matters are guarded against. Accordingly, crude flux may be employed successfully in many operations; as, for instance, in the ordinary operation for procuring the regulus of antimony.

Flux, *black*. Black flux is produced from the mixture of two parts of tartar and one part of nitre detonated together. As the quantity of nitre which enters into the composition of this flux is not sufficient to consume all the inflammable matter of the tartar, the alkali which remains after the detonation contains much black matter, of the nature of coal, and is therefore called black flux. This flux is designedly so prepared, that it shall contain a certain quantity of inflammable matter; for it is thereby capable, not only of facilitating the fusion of metallic earths like the white flux, but also of reviving these metals. From this property it is also called reducing flux; the black flux, therefore, or crude flux made with such proportions of the ingredients as to be convertible into black flux, ought always to be used when considered as metallic matters are at once to be fused and reduced. See Fusion.

FLUXION, in mathematics, denotes the velocity by which the fluents or flowing quantities, increase or decrease; and may be positive or negative, according as it relates to an increment or decrement.

The doctrine of fluxions, first invented by sir Isaac Newton, is of great use in the investigation of curves, and in the discovery of the quadratures of curvilinear spaces, and their rectifications. In this method, magnitudes are conceived to be generated by motion, and the velocity of the generating motion is the fluxion of the magnitude. Thus, the velocity of the point that describes a line, is its fluxion, and measures its increase or decrease. When the motion of this point is uniform, its fluxion or velocity is constant, and may be measured by the space described in a given time. But when the motion varies, the fluxion or velocity at any given point is measured by the space that would be described in a given time, if the motion was to be continued uniformly from that term.

Thus let the point m be conceived to move from A,

A ———————— m ———————— m .... r
R

and generate the variable right line Am, by a motion any how regulated; and let its velocity, when it arrives at any proposed position or point R, be such as would, was it to continue uniform from that point, be sufficient to describe the line Rr, in the given time allotted for the fluxion, then will Rr be the fluxion of the variable line Am, in the term or point R. The fluxion of a plain surface is conceived in like manner, by supposing a given right line $m\,n$ (plate LXIV. Miscel. fig. 89) to move parallel to itself, in the plane of the parallel and immoveable lines AF and BG; for if, as above, Rr be taken to express the fluxion of the line Am, and the rectangle RrsS be completed: then that rectangle, being the space which would be uniformly described by the generating line mn, in the time that Am would be uniformly increased by mr, is therefore the fluxion of the generated rectangle Bm, in that position. If the length of the generating line mn continually varies, the fluxion of the area will still be expounded by a rectangle under that line, and the fluxion of the abciss or base; for let the curvilinear space Anm (fig. 90) be generated by the continual and parallel motion of the variable line mn; and let Rr be the fluxion of the base or absciss Am, as before; then the rectangle RrsS, will be the fluxion of the generated space Amn. Because, if the length and velocity of the generating line mn were to continue invariable from the position RS, the rectangle RrsS would then be uniformly generated with the very velocity wherewith it begins to be generated, or with which the space Amn is increased in that position.

Fluxions, *Notation of.* Invariable quantities, or those which neither increase or decrease, are represented by the first letters of the alphabet, as a, b, c, d, &c.

and the variable or flowing quantities by the last letters, as v, w, x, y, z; thus, the diameter of a given circle may be denoted by a; and the sine of any arch thereof, considered as variable, by x. The fluxion of a quantity represented by a single letter, is expressed by the same letter with a dot or full point over it: thus, the fluxion of x is represented by $\dot{x}$, and that of y by $\dot{y}$. And, because these fluxions are themselves often variable quantities, the velocities with which they either increase or decrease, are the fluxions of the former fluxions, which may be called second fluxions, and are denoted by the same letters with two dots over them, as $\ddot{x}$, $\ddot{y}$. In the same manner the fluxions of second fluxions are called third fluxions, and denoted by the same letters with three dots over them, as $\dddot{x}$, $\dddot{y}$; and so on for fourth, fifth, &c. fluxions.

The whole doctrine of fluxions consists in solving the two following problems, viz. 1. From the fluent, or variable flowing quantity given, to find the fluxion; which constitute what is called the direct method of fluxions. 2. From the fluxion given, to find the fluent, or flowing quantity; which makes the inverse method of fluxions.

Direct Method of Fluxions.—The doctrine of this part of fluxions is comprized in these rules:

1. To find the fluxion of any simple variable quantity, the rule is to place a dot over it: thus, the fluxion of x is $\dot{x}$, and of y, $\dot{y}$. Again, the fluxion of the compound quantity $x+y$, is $\dot{x}+\dot{y}$; also the fluxion of $x-y$, is $\dot{x}-\dot{y}$.

2. To find the fluxion of any given power of a variable quantity, multiply the fluxion of the root by the exponent of the power, and the product by that power of the same root, whose exponent is less by unity than the given exponent. This rule is expressed more briefly, in algebraical character, by $nx^{n-1}\dot{x}$ = the fluxion of x^n. Thus, the fluxion of x^3 is $\dot{x} \times 3 \times x^2 = 3x^2\dot{x}$; and the fluxion of x^5 is $\dot{x} \times 5 \times x^4 = 5x^4\dot{x}$. In the same manner the fluxion of $\overline{a+y}|^7$ is $7\dot{y} \times \overline{a+y}^6$; for the quantity a being constant, $\dot{y}$ is the true fluxion of the root $a+y$. Again, the fluxion of $a^2+z^2\ ^{\frac{3}{2}}$ will be $\frac{3}{2} \times 2z\dot{z} \times \overline{a^2+z^2}|^{\frac{1}{2}}$: for here, x being put $= a^2+z^2$, we have $\dot{x} = 2z\dot{z}$; and therefore $\frac{3}{2}x^{\frac{1}{2}}\dot{x}$, for the fluxion of $x^{\frac{3}{2}}$ (or $a^2+z^2\ ^{\frac{3}{2}}$) is $= 3z\dot{z}\sqrt{a^2+z^2}$.

3. To find the fluxion of the product of several variable quantities, multiply the fluxion of each, by the product of the rest of the quantities; and the sum of the products, thus arising, will be the fluxion sought. Thus, the fluxion of xy is $\dot{x}y + \dot{y}x$; that of xyz, is $\dot{x}yz + \dot{y}xz + \dot{z}xy$; and that of $vxyz$, is $\dot{v}xyz + \dot{x}vyz + \dot{y}vxz + \dot{z}vxy$. Again, the fluxion of $x + x \times b - y = ab + bx - ay - xy$, is $b\dot{x} - a\dot{y} - \dot{x}y - \dot{y}x$.

4. To find the fluxion of a fraction, the rule is, from the fluxion of the numerator multiplied by the denominator, subtract the fluxion of the denominator multiplied by the numerator, and divide the remainder by the square of the denominator. Thus the fluxion of $\frac{x}{y}$, is $\frac{y\dot{x} - x\dot{y}}{y^2}$; that of $\frac{x}{x+y}$, is $\frac{\dot{x} \times \overline{x+y} - \overline{\dot{x}+\dot{y}} \times x}{\overline{x+y}|^2} = \frac{y\dot{x} - x\dot{y}}{\overline{x+y}|^2}$; and that of $\frac{x+y+z}{x+y}$, or $1 + \frac{z}{x+y}$, is $\frac{\dot{z} \times \overline{x+y} - \overline{\dot{x}+\dot{y}} \times z}{\overline{x+y}|^2}$; and so of others.

In the examples hitherto given, each is resolved by its own particular rule: but in those that follow, the use of two or more of the above rules is requisite: thus (by rules 2. and 3.) the fluxion of x^2y^2 is found to be $2x^2y\dot{y} + 2y^2x\dot{x}$; that of $\frac{x^2}{y^2}$, is found (by rules 2. and 4.) to be $\frac{2y^2x\dot{x} - 2x^2y\dot{y}}{y^4}$; and that of $\frac{x^2y^2}{z}$, is (by rules 2. 3. and 4.) found to be $\frac{\overline{2x^2y\dot{y} + 2y^2x\dot{x}} \times z - x^2y^2\dot{z}}{z^2}$.

5. When the proposed quantity is affected by a co-efficient, or constant multiplicator, the fluxion found as above must be multiplied by that co-efficient or multiplicator: thus, the fluxion of $5x^3$, is $15x^2\dot{x}$; for the fluxion of x^3 is $3x^2\dot{x}$, which, multiplied by 5, gives $15x^2\dot{x}$. And, in the very same manner, the fluxion of ax^n will be $nax^{n-1}\dot{x}$.

Having thus explained the manner of determining the first fluxions of variable quantities, it remains to say something of second, third, &c. fluxions. We have already observed, that the second fluxion of a quantity is the fluxion of the first fluxion; and by the third fluxion is meant the fluxion of the second; the fourth, of the third, and so on. The fluxions, therefore, of every order, are only the measures of the velocities by which their respective flowing quantities, viz. the fluxions of the immediately preceding order, are generated. Hence it appears, that a second fluxion always shows the rate of the increase or decrease of the first fluxion; and that the third, fourth, &c. the fluxions differ in nothing, except their order and notation, from first fluxions; and therefore, are also determinable in the very same manner, by the rules already laid down: thus (by rule 4.) the (first) fluxion of x^3 is $3x^2\dot{x}$; and if $\dot{x}$ is supposed constant, that is, if the root x be generated with an equable or uniform velocity, the fluxion of $3x^2\dot{x}$ (or $3\dot{x} \times x^2$) again taken (by the same rule) will be $3\dot{x} \times 2x\dot{x}$, or $6x\dot{x}^2$; which, therefore, is the second fluxion of x^3. Again, the third fluxion of x^3, or the fluxion of $6x\dot{x}^2$, is found to be $6\dot{x}^3$; further than which we cannot go in this case, because the last fluxion, $6\dot{x}^3$, is here a constant quantity.

In the preceding example, the root x is supposed to be generated with an equable velocity: but if the velocity be an increasing or decreasing one, then $\dot{x}$, expressing the measure thereof, being variable, will also have its fluxion, which is denoted, as said above, by $\ddot{x}$; and the fluxion of $\ddot{x}$ by $\dddot{x}$, and so on with respect to the higher orders.

Here follow some examples, in which the root x (or y) is supposed to be generated with a variable velocity. Thus, the fluxion of x^3 being $3x^2\dot{x}$ (or $3x^2 \times \dot{x}$), the fluxion of $3x^2 \times \dot{x}$, considered as a rectangle, will (by rule 3.) be found to be $6x\dot{x} \times \dot{x} + 3x^2 \times \ddot{x} = 6x\dot{x}^2 + 3x^2\ddot{x}$; which is the second fluxion of x^3. Moreover, from the fluxion last found, we shall in like manner get $6\dot{x} \times x^2 + 6x \times$

$2\dot{x}\ddot{x} + 6x\dot{x} \times \ddot{x} + 3x^2 \times \dddot{x}$ (or $6\dot{x}^3 + 18x\dot{x}\ddot{x} + 3x^2\dddot{x}$) for the third fluxion of x^3. Thus also, if $\dot{y} = nx^{n-1}\dot{x}$, then will $\ddot{y} = n \times \overline{n-1} \times x^{n-2}\dot{x}^2 + n\ddot{x}x^{n-1}$; and if $\dot{z}^2 = \dot{x}\dot{y}$, then will $2\dot{z}\ddot{z} = \dot{x}\ddot{y} + \dot{y}\ddot{x}$: and so of others.

The reader is here desired, once for all, to take particular notice, that the fluxions of all kinds and orders whatever, are contemporaneous, or such as may be generated together, with their respective velocities, in one and the same time.

Inverse Method of Fluxions, or the manner of determining the fluents of given fluxions.

If what is already delivered, concerning the direct method, be duly considered, there will be no great difficulty in conceiving the reasons of the inverse method: though the difficulties that occur in this last part, upon another account, are indeed vastly greater. It is an easy matter, or not imposible at most, to find the fluxion of any flowing quantity whatever; but, in the inverse method, the case is quite otherwise; for, as there is no method for deducing the fluent from the fluxion *a priori*, by a direct investigation; so it is impossible to lay down rules for any other forms of fluxions, than those particular ones that we know, from the direct method, belong to such kinds of flowing quantities; thus, for example, the fluent of $2x\dot{x}$ is known to be x^2; because, by the direct method, the fluxion of x^2 is found to be $2x\dot{x}$: but the fluent of $y\dot{x}$ is unknown, since no expression has been discovered that produces $y\dot{x}$ for its fluxion. Be this as it will, the following rules are those used by the best mathematicians, for finding the fluents of given fluxions.

1. To find the fluent of any simple fluxion, you need only write the letters without the dots over them: thus, the fluent of $\dot{x}$ is x, and that of $a\dot{x} + b\dot{y}$, is $ax + by$.

2. To assign the fluent of any power of a variable quantity, multiplied by the fluxion of the root; first divide by the fluxion of the root, add unity to the exponent of the power, and divide by the exponent so increased; for, dividing the fluxion $nx^{n-1}\dot{x}$ by $\dot{x}$, it becomes nx^{n-1}; and adding 1 to the exponent $(n-1)$ we have nx^n; which, divided by n, gives x^n, the true fluent of $nx^{n-1}\dot{x}$. Hence, by the same rule, the fluent of $3x^2\dot{x}$ will $= x^3$; that of $2x^5\dot{x} = \frac{x^6}{3}$; that of $y^{\frac{1}{2}}\dot{y} = \frac{2}{3}y^{\frac{3}{2}}$; that of $ay^{\frac{5}{3}}\dot{y} = \frac{3ay^{\frac{8}{3}}}{8}$; and that of $y^{\frac{m}{n}}\dot{y} = \frac{y^{\frac{m}{n}+1}}{\frac{m}{n}+1} = \frac{ny^{\frac{m+n}{n}}}{m+n}$; that of $\frac{a\dot{x}}{x^n}$, or $a\dot{x}x^{-n}$ $= \frac{ax^{1-n}}{1-n}$; that of $\overline{a+z}|^3 \times \dot{z} = \frac{\overline{a+z}|^4}{4}$; and that of $\overline{a^m + z^m}|^n \times z^{m-1}\dot{z} = \frac{\overline{a^m + z^m}|^{n+1}}{m \times \overline{n+1}}$.

In assigning the fluents of given fluxions, it ought to be considered, whether the flowing quantity, found as above, requires the addition or subtraction of some constant quantity, to render it complete: thus, for instance the fluent of $nx^{n-1}\dot{x}$ may be either represented by x^n or by $x^n \pm a$; for a being a constant quantity, the fluxion of $x^n \pm a$, as well as of x^n, is $nx^{n-1}\dot{x}$.

Hence it appears, that the variable part of a fluent only can be assigned by the common method, the constant part being only assignable from the particular nature of the problem. Now to do this, the best way is to consider how much the variable part of the fluent first found, differs from the truth, when the quantity which the whole fluent ought to express is equal to nothing: then that difference, added to, or subtracted from, the said variable part, as occasion requires, will give the fluent truly corrected. To make this plainer by an example or two, let $\dot{y} = \overline{a+x}|^3 \times \dot{x}$. Here we first find $y = \frac{\overline{a+x}|^4}{4}$; but when $y = 0$, then $\frac{\overline{a+x}|^4}{4}$ becomes $= \frac{a^4}{4}$: since x, by hypothesis, is then $= 0$: therefore $\frac{\overline{a+x}|^4}{4}$ always exceeds y by $\frac{a^4}{4}$; and so the fluent, properly corrected, will be $y = \frac{\overline{a+x}|^4 - a^4}{4} = a^3x + \frac{3a^2x^2}{2} + ax^3 + \frac{x^4}{4}$. Again, let $\dot{y} = \overline{a^m + x^m}|^n \times x^{m-1}\dot{x}$: here we first have $y = \frac{\overline{a^m + x^m}|^{n+1}}{m \times \overline{n+1}}$; and making $y = 0$, the latter part of the equation becomes $\frac{\overline{a^m}|^{n+1}}{m \times \overline{n+1}} = \frac{a^{mn+m}}{m \times \overline{n+1}}$; whence the equation or fluent, properly corrected, is $y = \frac{\overline{a^m + x^m}|^{n+1} - a^{mn+m}}{m \times \overline{n+1}}$. Hitherto x and y are both supposed equal to nothing, at the same time; which will not always be the case: thus, for instance, though the sine and tangent of an arch are both equal to nothing, when the arch itself is so; yet the secant is then equal to the radius. It will therefore be proper to add some examples, in which the value of y is equal to nothing, when that of x is equal to any given quantity a. Thus, let the equation $\dot{y} = x^2\dot{x}$ be proposed; whereof the fluent first found is $y = \frac{x^3}{3}$; but when $y = 0$, then $\frac{x^3}{3} = \frac{a^3}{3}$, by the hypothesis; therefore the fluent, corrected, is $y = \frac{x^3 - a^3}{3}$. Again, suppose $(\dot{y} = \overline{-x^n\dot{x}})$; then will $y = -\frac{x^{n+1}}{n+1}$; which, corrected, becomes $y = \frac{a^{n+1} - x^{n+1}}{n+1}$. And, lastly, if $\dot{y} = \overline{c^3 + bx^2}|^{\frac{1}{2}} \times x\dot{x}$; then, first, $y = \frac{\overline{c^3 + bx^2}|^{\frac{3}{2}}}{3b}$; therefore, the fluent corrected, is $y = \frac{\overline{c^3 + bx^2}|^{\frac{3}{2}} - \overline{c^3 + ba^2}|^{\frac{3}{2}}}{3b}$.

3. To find the fluents of such fluxionary expressions as involve two or more variable quantities, substitute, instead of such fluxion, its respective flowing quantity; and, adding all the terms together, divide the sum by the number of terms, and the quotient will be the fluent. Thus, the fluent of $\dot{x}y + \dot{y}x = \frac{xy + yx}{2} = \frac{2xy}{2} = xy$; and the fluent of $\dot{x}yz + \dot{y}xz + \dot{z}yx = \frac{xyz + xyz + xyz}{3} = \frac{3xyz}{3} = xyz$. But it seldom happens that these kinds of fluxions, which involve two variable quantities in one term, and yet admit of known and perfect fluents, are to be met with in practice.

Having thus shown the manner of finding such fluents as can be truly exhibited in algebraic terms, it remains now to say something with regard to those other forms of expressions involving one variable quantity only; which yet are so affected by compound divisors and radical quantities, that their fluents cannot be accurately determined by any method whatsoever. The only method with regard to these, of which there are innumerable kinds, is to find their fluents by approximation, which, by the method of infinite series, may be done to any degree of exactness. See the article SERIES.

Thus, if it were proposed to find the fluent of $\frac{a\dot{x}}{a-x}$, it becomes necessary to throw the fluxion into an infinite series, by dividing $a\dot{x}$ by $a-x$: thus, $a\dot{x} \div \overline{a-x} = \dot{x} + \frac{x\dot{x}}{a} + \frac{x^2\dot{x}}{a^2} + \frac{x^3\dot{x}}{a^3} + \frac{x^4\dot{x}}{a^4} +$, &c. Now the fluent of each term of this series, may be found by the foregoing rules to be $x + \frac{x^2}{2a} + \frac{x^3}{3a^2} + \frac{x^4}{4a^3} + \frac{x^5}{5a^4} +$, &c.

Again, to approximate the fluent of $\frac{\overline{a^2-x^2}|^{\frac{1}{2}} \times x^n \dot{x}}{\overline{c^2-x^2}|^{\frac{1}{2}}}$, we first find the value of $\frac{\overline{a^2-x^2}|^{\frac{1}{2}}}{\overline{c^2-x^2}|^{\frac{1}{2}}}$, expressed in a series, to be $\frac{a}{c} + \overline{\frac{a}{2c^3} - \frac{1}{2ac}} \times x^2 + \overline{\frac{3a}{8c^5} - \frac{1}{4ac^3} - \frac{1}{8a^3c}} \times x^4 + \overline{\frac{5a}{16c^7} - \frac{3}{16ac^5} - \frac{1}{16a^3c^3} - \frac{1}{16a^5c}} \times x^6 +$, &c. which value being multiplied by $x^n\dot{x}$, and the fluent taken by the rules laid down, we get $\frac{ax^{n+1}}{\overline{n+1} \times c} + \overline{\frac{a}{2c^3} - \frac{1}{2ac}} \times \frac{x^{n+3}}{n+3} + \overline{\frac{3a}{8c^5} - \frac{1}{4ac^3} - \frac{1}{8a^3c}} \times \frac{x^{n+5}}{n+5} + \overline{\frac{5a}{15c^7} - \frac{3}{16ac^5} - \frac{1}{16a^3c^3} - \frac{1}{16a^5c}} \frac{x^{n+7}}{n+7} +$, &c.

In order to show the usefulness of fluxions, we shall give an example or two. Thus, suppose it were required, (1) To divide a given right line AB into two such parts, AC, CB, that their products or rectangles may be the greatest possible. Let $AB = a$, and let the part AC, considered as variable (by the motion of C towards B) be denoted by x. Then BC being $= a - x$, we have $AC \times BC = ax - x^2$, whose fluxion $a\dot{x} - 2x\dot{x}$ being put $= 0$, we get $a\dot{x} = 2x\dot{x}$; and, consequently, $x = \frac{1}{2}a$. Hence it appears that AC (or x) must be half of AB.

(2) To find the fraction which shall exceed its cube by the greatest quantity possible: Let x denote a variable quantity; then the excess of x above x^3, being represented by $x - x^3$, if the fluxion of it be taken, we shall have $\dot{x} - 3x^2\dot{x} = 0$; therefore $1 = 3x^2$, $x^2 = \frac{1}{3}$, and $x = \sqrt{\frac{1}{3}}$.

(3) To determine the greatest rectangle that can be inscribed in a given triangle. See Plate LXIV. Miscel. fig. 91. Put $AC = b$, and its altitude $BD = a$: let the altitude BS of the inscribed rectangle an, considered as variable, be denoted by x. Then, since AC and ac are parallel, it will be BD (a) : AC (b) : : DS $(a-x)$: $\frac{ab-bx}{a}$ = the line ac. And the area of the rectangle, or $ac \times BS = \frac{abx - bx^2}{a}$, the fluxion of which is $\frac{ab\dot{x} - 2bx\dot{x}}{a}$, and being put equal to 0, we have $a = 2x$, and $x = \frac{a}{2}$. Hence the greatest inscribed rectangle is that, the altitude of which is half the altitude of the triangle.

(4) Of all right-angled plain triangles, containing the same given area, to find that of which the sum of the legs AB + BC is the least possible. Let one leg AB be denoted by x, and the area of the triangle by a, then the other leg will be $\frac{2a}{x}$, the fluxion of the sum is $\dot{x} - \frac{2a\dot{x}}{x^2} = 0$: therefore $x^2 = 2a$, and $x = \sqrt{2a}$. Whence BC $= \left(\frac{2a}{x}\right) = \frac{2a}{\sqrt{2a}} = \sqrt{2a}$. Hence the triangle is isosceles.

(5) To determine the dimensions of the least isosceles triangle, ACD, fig. 92, that can circumscribe a given circle. Let the distance OD of the vertex of the triangle from the centre of the circle be called x, and the remaining part OB, or radius, be represented by a; then, if OS perpendicular to DC be drawn, we have $DS = \sqrt{x^2 - a^2}$: and since DS : OS : : DB : BC, we have $BC = \frac{a \times \overline{x+a}}{\sqrt{x^2-a^2}}$, which multiplied by BD or $x + a$, gives $\frac{a \times \overline{x+a}|^2}{\sqrt{x^2-a^2}}$ for the area of the triangle. Which being a minimum, its square is also a minimum, consequently $\frac{\overline{x+a}|^4}{x^2-a^2}$, or its equal $\frac{\overline{x+a}|^3}{x-a}$, a minimum also; the fluxion of which is $\frac{3\dot{x} \times \overline{x+a}|^2 \times \overline{x-a} - \dot{x} \times \overline{x+a}|^3}{\overline{x-a}|^2} = 0$; this being divided by $\frac{\dot{x} \times \overline{x+a}|^2}{\overline{x-a}|^2}$, we get $3 \times \overline{x-a} - \overline{x+a} = 0$, whence $2x = 4a$, and $x = 2a$. Therefore OD is equal

to 2OS, and DC = 2BC = AC; and so the triangle ACD, when the least pssible, is equilateral.

(6) Again, suppose it were required to find the solid content of a spheriod, AFBH (plate LXIV. Micel. fig. 93). Let the axis AB, about which the solid is generated, be $= a$, the radius $= p = 1$, and the other axis FH of the generating ellipsis $= b$; then, from the property of the ellipsis, we have $a^2 : b^2 :: AD \times BD\ (x \times \overline{a - x}) : DE^2\ (y^2)$. Hence $y^2 = \frac{b^2}{a^2} \times \overline{ax - xx}$; and the fluxion of the solid $\dot{s}\ (= py^2\dot{x}) = \frac{pb^2}{a^2} \times \overline{ax\dot{x} - x^2\dot{x}}$; and the solidity $s = \frac{pb^2}{a^2} \times \frac{1}{2}axx - \frac{1}{3}x^3 =$ the segment AIE; which, when AD $(x) =$ AB (a), becomes $\left(\frac{pb^2}{a^2} \times \frac{1}{2}a^3 - \frac{1}{3}a^3\right) \frac{1}{6}pab^2 =$ the content of the whole spheroid Where, if b (FH) be taken $= a$ (AB), we shall get $\frac{1}{6}pa^3$ for the true content of the sphere, whose diameter is a. Hence a sphere or spheriod is $\frac{2}{3}$ of its circumscribing cylinder: for the area of the circle FH being expressed by $\frac{pb^2}{4}$, the content of the cylinder, whose diameter is FH, and altitude AB, will be $\frac{pb^2a}{4}$; of which $\frac{1}{6}pab^2$ is evidently two-third parts.

[The preceding articles serve to show the general principles of the doctrine of fluxions; but the reader who is desirous of obtaining more information on the subject is referred to the following authors, viz. Woodhouse, Vince, and Simpson. It is often convenient for the mathematician to have a table of fluents which will serve for the more readily finding the fluents of other expressions. The following table exhibits the fluxions, and opposite to them the corresponding fluents.

N. B. The logarisms here used are of the hyperbolic kind.

FLUXIONS.	FLUENTS.
$\overline{a^n + bx^n}\rceil^m \times x^{n-1}\dot{x}.$	$\left.\frac{\overline{a^n + bx^n}\rceil^{m+1} - \overline{a^n + bc^n}\rceil^{m+1}}{bn . \overline{m+1}}\right\}$ $c = x$ when $fl = 0$.
$\frac{x^{nm-1}\dot{x}}{\overline{a^n + bx^n}\rceil^{m+1}}.$	$\left.\frac{1}{nma^n} \times \frac{x^{nm}}{\overline{a^n + bx^n}\rceil^m} - \frac{c^{nm}}{\overline{a^n + bc^n}\rceil^m}.\right\}$ $c = x$ when $fl = 0$.
$\frac{x^{n-1}\dot{x}}{(a^{2n} - x^{2n})^{\frac{1}{2}}}.$	$\left.C + \frac{1}{na^n} \times \text{circular arc. rad. } a^n\text{, sine } x^n.\right\}$ C is the correction to be applied.
$\frac{x^{n-1}\dot{x}}{a^{2n} + x^{2n}}.$	$C + \frac{1}{na^{2n}} \times \text{circ. arc. rad. } a^n\text{, tang } x^n.$
$\left.\frac{\dot{x}}{\overline{a + bx} \cdot \overline{d + ex}}\right\} \frac{d}{e} >$ or $< \frac{a}{b}$	$\left.\frac{1}{bd - ae} \times \log. \frac{d + ec}{a + bc} \times \frac{a + bx}{d + ex}\right\}$ $c = x$ when $fl = 0$.
$\dot{x}(dx - x^2)^{\frac{1}{2}}.$	$\frac{1}{2}$ circ. seg. to diameter d and versed sine x.
$\dot{x}y^x \log. y + xy^{x-1}\dot{y}.$	$y^x.$
$\frac{\dot{x}}{(a^2 + 2bdx - d^2x^2)^{\frac{1}{2}}}.$	$C + \frac{1}{d} \times \text{circ. arc. rad. 1. sine } \frac{dx - b}{(a^2 + b^2)^{\frac{1}{2}}}.$
$\frac{\dot{x}}{(a^2 + 2bdx + d^2x^2)^{\frac{1}{2}}}.$	$C + \frac{1}{d} \times \log. \overline{b + dx + (a^2 + 2bdx + d^2x^2)^{\frac{1}{2}}}.$
$c^{nx}\dot{x}.$	$\frac{c^{nx}}{n. \log. c}.$
$\frac{x^{\frac{1}{2}n - 1}\dot{x}}{(\pm a + x^n)^{\frac{1}{2}}}.$	$\frac{2}{n} \log. x^{\frac{n}{2}} + (\pm a + x^n)^{\frac{1}{2}}.$

FLUXIONS.	FLUENTS.
$\frac{x^3\dot{x}}{a-x}$.	$-\frac{1}{3}x^3-\frac{1}{2}ax^2-a^2x+a^3\times\log.\ (a-x)$.
$cx\dot{x}\times\frac{d^2x^2+2adhx+a^2h^2}{h^2}$.	$ch^2\times\frac{3d^2+8ad+6a^2}{12}\Big\}\ x=h$.
$(a+x^n)^m x^{2n-1}\dot{x}$.	$\frac{(a+x^n)^{m+1}}{n}\times\frac{(m+1)x^n-a}{m+1.\ m+2}$.
$5(\frac{1}{3}-z^2)^{\frac{1}{2}}z^{-8}\dot{z}$.	$\frac{-3(\frac{1}{3}-z^2)^{\frac{3}{2}}}{7z^7}\times(5+12z^2+24z^4)$. [r]

FLY, in zoology, a large order of insects, the distinguishing characteristic of which is, that their wings are transparent; by this they are distinguished from beetles, butter-flies, and grasshoppers. See MUSCA.

FLY, in mechanics, a cross with leaden weights at its ends, or rather a heavy wheel at right angles to the axis of a windlass, jack, &c.; by means of which the force of the power, whatever it may be, is not only preserved, but equally distributed in all parts of the revolution of the machine. See MECHANICS.

The fly may be applied to several sorts of engines, whether moved by men, horses, wind, or water, or any other animate or inanimate power; and is of great use in those parts of an engine which have a quick circular motion, and where the power or the resistance acts unequally in the different parts of a revolution. This has made some people imagine, that the fly adds a new power; but though it may be truly said to facilitate the motion, by making it more uniform, yet upon the whole it causes a loss of power, and not an increase; for as the fly has no motion of its own, it certainly requires a constant force to keep it in motion; not to mention the friction of the pivots of the axis, and the resistance of the air. The reason, therefore, why the fly becomes useful in many engines, is not that it adds a new force to them; but because, in cases where the power acts unequally, it serves as a moderator to make the motion of revolution almost every where equal: for as the fly has accumulated in itself a great degree of power, which it equally and gradually exerts, and as equally and gradually receives, it makes the motion in all parts of the revolution pretty nearly equal and uniform. The consequence of this is, that the engine becomes more easy and convenient to be acted on and moved by the impelling force; and this is the only benefit obtained by the fly.

The best form for a fly, is that of a heavy wheel or circle, of a fit size, as this will not only meet with less resistance from the air, but being continuous, and the weight every where equally distributed through the perimeter of the wheel, the motion will be more easy, uniform, and regular. In this form, the fly is more aptly applied to the perpendicular drill, which it likewise serves to keep upright by its centrifugal force: also to a windlass or common winch, where the motion is quick; for in pulling upwards from the lower part, a person can exercise more power than in thrusting forward in the upper quarter; where, of course, part of his force would be lost, was it not accumulated and conserved in the equable motion of the fly. Hence, by this means, a man may work all day in drawing up a weight of 40lb. whereas 30lb. would create him more labour in a day without the fly.

In order to calculate the force of the fly joined to the screw for stamping the image upon coins, let us suppose the two arms of the fly to be each fifteen inches long, measuring from the centre of the weight to the axis of motion, the weight to be fifty pounds each, and the diameter of the axis pressing upon the dye, to be one inch. If every stroke is made in half a second, and the weights describe an half-circumference, which in this case will be four feet, the velocity will at the instant of the stroke be at the rate of eight feet in a second, so that the momentum of it will be 800; but the arms of the fly being as levers, each fifteen inches long, whilst the semi-axis is only half an inch, we must increase this force thirty times, which will give 24000; an immense force equal to 100lb. falling 120 feet, or near two seconds in time; or to a body of 750lb. falling $16\frac{1}{12}$ feet, or one second in time. Some of the engines for coining crown-pieces have the arms of the fly five times as long, and the weights twice as heavy; so that the effect is ten times greater.

FLY, in the sea-language, that part of the mariner's compass, on which the several winds or points are drawn.

Let fly the sheet, is a word of command to let loose the sheet, in case of a gust of wind, lest the ship should overset, or spend her topsails and masts; which is prevented by letting the sheet go amain, that it may hold no wind.

FLY-BOAT, a large vessel with a double prow, carrying from seven to eight hundred weight of goods.

FLY, *vegetable*, a very curious natural production, chiefly found in the West Indies. Excepting that it has no wings, it resembles the drone both in size and colour more than any other British insect. In the month of May it buries itself in the earth, and begins to vegetate. By the end of July, the tree is arrived at its full growth, and resembles a coral branch; and is about three inches high, and bears several little pods, which dropping off become worms, and thence flies, like the British caterpillar. Such was the account originally given of this extraordinary production. But several

boxes of these flies having been sent to Dr. Hill for examination, his report was this: "There is in Martinique a fungus of the clavaria kind, different in species from those hitherto known. It produces soboles from its sides; I call it therefore clavaria sobolifera. It grows on putrid animal bodies, as our fungus ex pede equino, from the dead horse's hoof. The cicada is common in Martinique, and in its nympha state, in which the old authors call it tettigometra: it buries itself under dead leaves to wait its change; and when the season is unfavourable, many perish. The seeds of the clavaria find a proper bed in this dead insect, and grow. The tettigometra is among the cicadæ in the British museum; the clavaria is just now known. This is the fact, and all the fact; though the untaught inhabitants suppose a fly to vegetate, and though there is a Spanish drawing of the plants growing into a trifoliate tree, and it has been figured with the creature flying with this tree upon its back." Edwards has taken notice of this extraordinary production in his Gleanings of Natural History.

FLYERS, in architecture, such stairs as go straight, and do not wind round.

FLYING, the progressive motion of a bird, or other winged animal, in the liquid air. The parts of birds chiefly concerned in flying, are the wings, by which they are sustained or wafted along. The tail, Messrs. Willughby, Ray, and many others, imagine to be principally employed in steering and turning the body in the air, as a rudder; but Borelli has put it beyond all doubt, that this is the least use of it, which is chiefly to assist the bird in its ascent and descent in the air; and to obviate the vacillations of the body and wings: for, as to turning to this or that side, it is performed by the wings and inclinations of the body, and but very little by the help of the tail. The flying of a bird, in effect, is quite a different thing from the rowing of a vessel. Birds do not vibrate their wings towards the tail, as oars are struck towards the stern, but waft them downwards; nor does the tail of the bird cut the air at right angles, as the rudder does the water, but is disposed horizontally, and preserves the same situation what way soever the bird turns.

In effect, as a vessel is turned about on its centre of gravity to the right, by a brisk application of the oars to the left, so a bird in beating the air with its right wing alone, towards the tail, will turn its fore part to the left. Thus pigeons, changing their course to the left, would labour with their right wing, keeping the other almost at rest. Birds of a long neck alter their course by the inclinations of their head and neck, which altering the course of gravity, the bird will proceed in a new direction.

The manner of flying is thus: The bird first bends his legs, and springs with a violent leap from the ground; then opens and expands the joints of his wings, so as to make a right line perpendicular to the sides of his body: thus the wings, with all the feathers in them, constitute one continued lamina. Being now raised a little above the horizon, and vibrating the wings with great force and velocity perpendicularly against the subject air, that fluid resists those succussions, both from its natural inactivity and elasticity, by means of which the whole body of the bird is protruded. The resistance the air makes to the withdrawing of the wings, and consequently the progress of the bird, will be so much the greater, as the waft or stroke of the fan of the wing is longer; but as the force of the wing is continually diminished by this resistance, when the two forces come to be in equilibrio, the bird will remain suspended in the same place: for the bird only ascends so long as the arch of air the wing describes, makes a resistance equal to the excess of the specific gravity of the bird above the air. If the air, therefore, is so rare as to give way with the same velocity that it is struck with, there will be no resistance, and consequently the bird can never mount. Birds never fly upwards in a perpendicular line, but always in a parabola. In a direct ascent, the natural and artificial tendency would oppose and destroy each other, so that the progress would be very slow. In a direct descent they would aid one another, so that the fall would be too precipitate.

Artificial FLYING, that attempted by men, by the assistance of mechanics.

The art of flying has been attempted by several persons in all ages. The Leucadians, out of superstition, are reported to have had a custom of precipitating a man from a high cliff into the sea, first fixing feathers, variously expanded, round his body, in order to break his fall. Friar Bacon, who lived five hundred years ago, not only affirms the art of flying possible, but assures us, that he himself knew how to make an engine in which a man sitting might be able to convey himself through the air, like a bird; and further adds, that there was then one who had tried it with success; but this method, which consisted of a couple of large, thin, hollow, copper globes, exhausted of the air, and sustaining a person who sat thereon, Dr. Hook shows to be impracticable. The philosophers of king Charles the Second's reign, were exceedingly busied about this art. The famous bishop Wilkins was so confident of success in it, that he says, he does not question that, in future ages, it will be as usual to hear a man call for his wings, when he is going a journey, as it is now to call for his boots.

FLYING ARMY, a small body under a lieutenant or major-general, sent to harass the country, intercept convoys, prevent the enemy's incursions, cover its own garrisons, and keep the enemy in continual alarm.

FLYING PINION, is part of a clock, having a fly, or fan, whereby to gather air, and so bridle the rapidity of the clock's motion, when the weight descends in the striking part. See CLOCKWORK.

FOCUS, in geometry and conic sections, is applied to certain points in the parabola, ellipsis, and hyperbola, where the rays reflected from all parts of these curves concur and meet.

FOCI of an ellipsis, are two points in the longest axis, on which as centres the figure is described. If from the foci two right lines are drawn, meeting one another in the periphery of the ellipsis, their sum will be always equal to the longest axis; and therefore when an ellipsis and its two axis are given, and the foci are required, you need only take half the longest axis in your compasses, and setting one foot in the end of the shorter, the other foot will cut the longer in the focus required.

FOCUS of an hyperbola, is that point in the axis, through which the latus rectum passes; from whence if

any two right lines are drawn meeting in either of the opposite hyperbolas, their difference will be equal to the principal axis.

Focus *of a parabola*, a point in the axis within the figure, distant from the vertex one fourth part of the latus rectum.

Focus, in optics, is the point in which the rays are collected, after they have undergone reflection or refraction. See Optics.

FODDER, in the civil law, is used for a prerogative that the prince has, to be provided of corn, and other meats for his horses, by the subjects, in his warlike expeditions.

Fodder, or Fother, in mining, a measure containing twenty-two hundred and a half weight, though in London but twenty hundred weight.

FOETUS. See Physiology.

FOG, or Mist, a meteor, consisting of condensed vapours, floating near the surface of the earth. Mists, according to lord Bacon, are imperfect condensations of the air, consisting of a large proportion of the air, and a small one of the aqueous vapour: and these happen in the winter, about the change of the weather from frost to thaw, or from thaw to frost; but in the summer and in the spring, from the expansion of the dew. If the vapours, which are raised plentifully from the earth and waters, either by the solar or subterraneous heat, do at their first entrance into the atmosphere meet with cold enough to condense them to a considerable degree, their specific gravity is by that means increased, and thus they will be stopped from ascending; and either return back in form of dew or of drizzling rain, or remain suspended some time in the form of a fog. Vapours may be seen on the high grounds as well as the low, but more especially about marshy places. They are easily dissipated by the wind, as also by the heat of the sun. They continue longest in the lowest grounds, because those places contain most moisture, and are least exposed to the action of the wind. Hence we may easily conceive, that fogs are only low clouds, or clouds in the lowest region of the air; as clouds are no other than fogs raised on high. When fogs stink, then the vapours are mixed with putrid and offensive exhalations. Objects viewed through fogs appear larger and more remote than through the common air. Mr. Boyle observes that, upon the coast of Coromandel, and most maritime parts of the East Indies, there are, notwithstanding the heat of the climate, annual fogs, so thick, as to occasion people of other nations who reside there, and even the more tender sort of the natives, to keep their houses close shut up. Fogs are commonly pretty strongly electrified, as appears from Mr. Cavallo's experiments upon them. See Meteorology.

FOIL, among glass-grinders, a sheet of tin, with quicksilver, &c. laid on the back-side of a looking-glass, to make it reflect. See Foliating of Looking-glasses.

Foil, among jewellers, a thin leaf of metal placed under a precious stone, in order to increase its brilliancy, or give it an agreeable and different colour. These foils are made either of copper, gold, or gold and silver together; the copper foils are commonly known by the name of Nuremberg, or German foils; they are prepared as follows: Procure the thinnest copper-plates you can get; beat these plates gently upon a well-polished anvil, with a polished hammer, as thin as possible; and placing them between two iron plates as thin as writing-paper, heat them in the fire; then boil the foils, in a pipkin, with equal quantities of tartar and salt, constantly stirring them till by boiling they become white; after which, taking them out, and drying them, give them another hammering till they are made fit for your purpose; however, care must be taken not to give the foils too much heat, for fear of melting, nor must they be too long boiled, for fear of attracting too much salt.

The manner of polishing these foils is as follows: take a plate of the best copper, one foot long, and about five or six inches wide, polished to the greatest perfection; bend this to a long convex, fasten it upon a half roll, and fix it to a bench or table; then take some chalk, washed as clean as possible, and filtred through a fine linen-cloth, till it is as fine as you can make it; and having laid some on the roll, and wetted the copper all over, lay your foils upon it, and with a polishing stone and the chalk, polish your foils till they are bright as a looking-glass; after which they must be dried, and laid up secure from dust.

FOLD-net, among sportsmen, a sort of net with which small birds are taken in the night, of which there are two sorts; the least may be managed by one man only, but the greatest must be carried by two, and used thus: let the net be fixed on both sides to two strong, straight, and light poles about twelve feet long, each man holding one of them; let there be one behind them, at the distance of two yards, to carry lights: the nets must be carried between the wind and the birds, which all naturally roost on their perches with their breasts against the wind; in consequence of this, he that beats the bushes on the other side of the hedge, will drive them out that way towards the light.

FOLDING *of sheep*. See Husbandry.

FOLIAGE, in architecture, is used for the representations of such flowers, leaves, branches, rinds, &c. whether natural or artificial, as are used for enrichments on capitals, friezes, pediments, &c.

FOLIATE, in the higher geometry, a name given by Mr. de Moivre to a curve of the second order, expressed by the equation $x^3+y^3=axy$; being a species of defective hyperbolas with one asymptote, and consisting of two infinite legs crossing one another, and forming a sort of leaf.

FOLIATING *of looking-glasses*, the spreading the plates over, after they are polished, with amalgam, in order to reflect the image. It is performed thus: a thin blotting paper is spread on the table, and sprinkled with fine chalk; and then a fine lamina or leaf of tin, called foil, is laid over the paper; upon this mercury is poured, which is to be distributed equally over the leaf with a hare's foot, or cotton: over this is laid a clean paper, and over that the glass plate, which is pressed down with the right-hand, and the paper drawn gently out with the left: this being done, the plate is covered with a thicker paper, and loaden with a greater weight, that the superfluous mercury may be driven out, and the tin adhere more closely to the glass. When it is dried, the weight is removed, and the looking-glass is complete. Some add an ounce of marcasite, melted by the fire; and, lest the mer-

cury should evaporate in smoke, pour it into cold water; and when cooled, squeeze it through a cloth or through leather.

Some add a quarter of an ounce of tin and lead to the marcasite, that the glass may dry the sooner.

FOLIATING *of globe looking-glasses*, is done as follows: Take five ounces of quick-silver, and one ounce of bismuth; of lead and tin half an ounce each: first put the lead and tin into fusion, then put in the bismuth, and when you perceive that in fusion too, let it stand till it is almost cold, and pour the quick-silver into it; after this, take the glass globe, which must be very clean, and the inside free from dust; make a paper funnel, which put into the hole of the globe, as near to the glass as you can, so that the amalgam when you pour it in, may not splash, and cause the glass to be full of spots; pour it in gently, and move it about, so that the amalgam may touch every where. If you find the amalgam begin to get curdly and fixed, then hold it over a gentle fire, and it will easily flow again. And if you find the amalgam too thin, add a little more lead, tin, and bismuth to it. The finer and clearer your globe is, the better will the looking-glass be.

FOLKMOTE, or FOLCMOTE, according to Kennet, was the common-council of all the inhabitants of a city, town, or borough; though Spelman will have the folkmote to have been a sort of annual parliament or convention of the bishops, thanes, aldermen, and freemen, on every May-day. Dr. Brady, on the contrary, tells us, that it was an inferior court, held before the king's-reeve, or his steward, every month, to do folk right.

FOMAHAUT, in astronomy, a star of the first magnitude, in the constellation Aquarius. See ASTRONOMY.

FOMENTATION, in medicine, the bathing any part of the body with a warm liquor.

FONTEVRAUD, or order of Fontevraud, a religious order instituted about the latter part of the 11th century. By the rules of this order the nuns were to keep silence for ever, and their faces to be always covered with their veils; and the monks wore a leathern girdle, at which hung a knife and sheath.

FONTANESIA, a genus of the diandria monogynia class and order. The calyx is four-parted, inferior: petals two, two-parted: capsule membranaceous, not opening, two-celled, one-seeded. There is one species, an herb of Syria.

FONTINALIS, water-moss, a genus of the natural order of musci, in the cryptogamia class of plants. The anthera is hooded; the calyptra, or covering of the anthera, sessile, inclosed in a perichætium or empalement of leaflets different from those of the rest of the plant. There are six species, all of them natives of Britain. They grow on the brinks of rivulets, and on the trunks of trees. The most remarkable is the antipyretica, with purple stalks. The Scandinavians line the insides of their chimneys with this moss, to defend them against the fire; for, contrary to the nature of all other mosses, this is scarcely capable of burning.

FOOD. See MATERIA MEDICA.

FOOD of plants. See PLANTS.

FOOT, a part of the body of most animals whereon they stand, walk, &c.

Animals are distinguished with respect to the number of their feet, into bipedes, two-footed; such are men and birds: quadrupeds, four-footed; which are most land animals; and multipedes, or many-footed, as insects. The reptile kind, as serpents, &c. have no feet; the crab kind of fish have ten feet, but most other fishes have no feet at all: the spider, mites, and polypuses, have eight; flies, grasshoppers, and butterflies, have six feet. Animals destined to swim, and water-fowl, have their toes webbed together, as the phocæ, goose, duck, &c. The fore feet of the mole, rabbit, &c. are wonderfully formed for digging and scratching up the earth, in order to make way for their head.

FOOT, in the Latin and Greek poetry, a metre or measure composed of a certain number of long and short syllables. These feet are commonly reckoned twenty-eight, of which some are simple, as consisting of two or three syllables, and therefore called disyllabic or trisyllabic feet; others are compound, consisting of four syllables, and are therefore called tetrasyllabic feet.

FOOT is also a long measure, consisting of twelve inches. Geometricians divide the foot into ten digits, and the digit into ten lines.

FOOT, *square*, is the same measure both in breadth and length, containing 144 square or superficial inches.

FOOT, *cubic*, or *solid*, is the same measure in all the three dimensions, length, breadth, and depth or thickness, containing 1728 cubic inches. The foot is of different lengths in different countries. The Paris royal foot exceeds the English by nine lines; the ancient Roman foot of the capitol, consisted of 4 palms, equal to $11\frac{7}{10}$ inches English; Rhineland or Leyden foot, by which the northern nations go, is to the Roman foot as 950 to 1000. The proportions of the principal feet of several nations, compared with the English, are as follow.

The English foot being divided into 1000 parts, or into 12 inches, the other feet will be as follow:

	1000 parts.	feet.	inch.	lines.
London or American foot	1000	0	12	0
Amsterdam	942	0	11	3
Antwerp	946	0	11	2
Bologna	1204	1	2	4
Bremen	964	0	11	6
Cologne	954	0	11	4
Copenhagen	965	0	11	6
Dantzick	944	0	11	3
Dort	1184	1	2	2
Frankfort on the Maine	948	0	11	4
The Greek	1007	1	0	1
Lorrain	958	0	11	4
Mantua	1569	1	6	8
Mechlin	919	0	11	0
Middleburg	991	0	11	9
Paris royal	1068	1	0	9

Riga	1831	1	9	9
Roman	967	0	11	6
Old Roman	970	0	11	8
Scotch	1005	1	0	$\frac{5}{7}$
Strasburg	920	0	11	0
Toledo	899	0	10	7
Turin	1062	1	0	7
Venice	1162	1	1	9

Foot of the forest, pes forestæ, in our ancient customs, contained eighteen inches, or $1\frac{1}{2}$ of the common foot.

Foot-level, among artificers, an instrument that serves as a foot-rule, a square, and a level. See the articles Level, Rule, and Square.

Foot-pace, or Half-pace, among carpenters, a pair of stairs, whereon, after four or six steps, you arrive at a broad place, where you may make two or three paces before you ascend another step. The design of this is, to ease the legs in ascending the rest of the steps.

FORAMEN, in anatomy, a name given to several apertures or perforations in divers parts of the body.

FORCE, in mechanics, denotes the cause of the change in the state of a body when being at rest it begins to move, or has a motion which is either not uniform, or not direct. See Mechanics.

FORCE, in our common law, is most usually applied in its worst sense, signifying unlawful violence. Force is either simple or compound: simple force is that which is so committed, that it is accompanied by no other crime; as if one by force shall enter into another man's possession, without doing any other unlawful act; mixed or compound force, is that violence which is committed with such a fact, as of itself only is criminal; as if one by force enters into another man's possession, and kills a man, or ravishes a woman there, &c.

All force is against law; and it is lawful to repel force by force. 1 Inst. 267.

Where a crime, in itself capital, is endeavoured to be committed by force, it is lawful to repel that force, by the death of the party attempting. 4 Black. 181.

FORCEPS, in surgery, &c. a pair of scissars for cutting off, or dividing, the fleshy membranous parts of the body, as occasion requires. See Surgery.

FORCER, or Forcing-pump, in mechanics, is a kind of pump in which there is a force or piston without a valve. See Hydraulics, and Fire-engine.

FORCIBLE entry and detainer. Forcible entry is a violent actual entry into a house or land, &c. or taking a distress of any person weaponed, whether he offers violence or fear of hurt to any there, or furiously drives any out of the possession thereof. West. Symbol. p. 2.

Where one or more persons armed with unusual weapons, violently enter into the house or land of another; or where they do not enter violently, if they forcibly put another out of his possession; or if one enters another's house without his consent, although the doors be open, &c. these are all forcible entries punishable by the law. Co. Lit. 257. So when a tenant keeps possession of the land at the end of his term against the landlord, it is a forcible detainer. 1 Haw. 145.

If any person is put out or disseised of any lands and tenements in a forcible manner; or put out peaceably, and after holden out with strong hand; the party grieved shall have assize of novel disseisin, or writ of trespass against the disseisor; and if he recovers (or if any alienation is made to defraud the possessor of his right, which is also declared by the statute to be void), he shall have treble damages, and the defendant shall also make fine and ransom to the king. 8 H. VI. c. 9. But as this action is at the suit of the party, and only for the right, it lies only where the entry for the defendant was not lawful; for though a man enters with force, where his entry is lawful, he shall not be punished by way of action, but he may be indicted by the statute, for the indictment is for the force and for the king, and he shall make fine to the king, be his right ever so good. Dalt. c. 129. He shall recover treble damages, as well for the mesne occupation, as for the first entry; and though he shall recover treble damages, he shall recover costs which shall be treble also; for the word damages includes costs of suit. 1 Inst. 257.

An indictment will lie at common law for a forcible entry, though generally brought on the statutes; but it must show on the face of it sufficient actual force. 3 Bur. 1702.

If the party grieved will lose the benefit of his treble damages and costs, he may have the assistance of the justices at the general session, by way of indictment on the statute 8 H. VI. which being found there, he shall be restored to his possession by a writ of restitution granted out of the same court to the sheriff. Dalt. c. 129.

Forcible entry and detainer is also punishable under the statute, by one justice of peace, and by certiorari. Dalt. c. 44.

Forcible marriage. If any person shall take away any woman having lands or goods, or that is heir apparent to her ancestor, by force and against her will, and afterwards she be married to him, or to another by his procurement, or defiled; he and also the procurers and receivers of such a woman, shall be adjudged principal felons. And by 39 Eliz. c. 9, the benefit of clergy is taken away from the principals, procurers, and accessaries before. And by 4 and 5 P. et M. c. 8, if any person shall take or convey away any unmarried woman under the age of sixteen (though not attended with force), he shall be imprisoned two years, or fined at the discretion of the court; and if he deflower her, or contract matrimony without consent of parents or guardians, he shall be imprisoned five years or fined, and the marrying of any person under 21 without such consent is void.

FORCING, among gardeners, signifies the making trees produce ripe fruit before their usual time.

Forcing of wine. See Wine.

FORE-Castle, *of a ship*, that part where the foremast stands. It is divided from the rest by a bulk-head. See Ship.

Fore-closed, in law, signifies the being shut out, and excluded or barred, the equity of redemption on mortgages, &c. See Mortgage.

Fore-foot, in the sea-language, signifies one ship's lying, or sailing, across another's way; as if two ships being under sail, and in ken of one another, one of them lying in her course with her stem so much a weather the other that holding on their several ways, neither of them altering their courses, the windward ship will run ahead of the other; then it is said, such a ship lies with the other's forefoot.

FOREIGN *attachment*, is an attachment of the goods of foreigners, found within a city or liberty, for the satisfaction of some citizen to whom the foreigner is indebted; or it signifies an attachment of a foreigner's money in the hands of another person.

Foreign *courts*. Upon a principle of the law of nations, every state being free, independent, and uncon-

trolable, the sentence of any foreign court of competent jurisdiction, is not to be called in question, but is admitted as evidence of the fact upon which it is founded. If however in such sentence any foreign jurisdiction should state the evidence, upon which its sentence or device is founded, subsequent evidence may be admitted to disprove such evidence, and consequently the sentence or decree which is a deduction from it. But where it is peremptorily given as a sentence, it is conclusive evidence which the English courts will not allow to be questioned.

FOREIGNERS, are persons subject to a foreign state to which they owe an allegiance, and although made free denizens or naturalized in Great Britain, they are nevertheless expressly disabled by the act of settlement from bearing offices in the government, from being members of the privy council, or members of parliament. See ALIEN.

FOREIGN *opposer*, or *apposer*, an officer in the exchequer to whom all sheriffs, after they are apposed of their sums out of the pipe-office, repair to be apposed by him of their green wax. He examines the sheriff's estreats with the record, and apposes the sheriff, what he says to every particular sum therein.

FOREIGN *plantations:* a writ of error lies here upon any of the judgments in foreign plantations, or in any dominions belonging to England. Vaugh. 402.

FOREIGN *plea:* a foreign plea is where the action is carried out of the county where it is laid, and is to be sworn, which a plea to the jurisdiction is not. Carth. 402.

FOREIGN *service*, is that whereby a mesne lord holds over of another, without the compass of his own fee; or that which a tenant performs either to his own lord, or to the lord paramount out of the fee. Bracton, lib. 2. c. 16.

FOREIGN *state*, is the dominion of a foreign power. Thus, if any foreign subject purchase goods in London, and then depart privately to his own country, the owner of the goods may have a certificate from the lord-mayor of London, on an affidavit being made of the sale and delivery of the goods, upon which the proper court in that state, will execute a legal process upon the party. At the instance of an embassador also or consul, any criminal flying from justice to any foreign state, may be delivered up to the laws of the country where the crime was committed. Where any contract is made abroad if the party is resident in England, it may be recovered by the English courts.

FOREIGN *seamen*, serving two years on board British ships, whether of war, trade, or privateers, during the time of war, shall be deemed natural-born subjects.

FOREJUDGER, a judgment whereby a man is deprived, or put out, of the thing in question.

FOREJUDGED *the court*, is when an officer or attorney of the court of common pleas is expelled the same for some offence, or for not appearing to an action by bill filed against him; and in the latter he is not to be readmitted till he shall appear. By 2 H. IV. c. 8. he shall lose his office and be forejudged the court.

FORLORN-HOPE, in the military art, signifies men detached from several regiments, or otherwise appointed, to make the first attack in day of battle, or at a siege, to storm the counterscarp, mount the breach, &c.

FOREMAST of a ship, that which carries the foresail and fore-top-sail yards. Its length is usually $\frac{8}{9}$ of the mainmast; and the fore-top-gallant-mast is $\frac{1}{2}$ the length of the fore-top-mast.

FOREMAST-MEN, are those on board a ship that take in the top-sails, sling the yards, furl the sails, bowse, trice, and take their turn at the helm, &c.

FORE-REACH, in the sea-language: a ship is said to fore-reach upon another, when both sailing together, one sails better, or outgoes the other.

FORESTS, in England are waste grounds belonging to the king, replenished with all manner of beasts of chace or venery, which are under the king's protection, for the sake of his royal recreation and delight; and to that end, and for the preservation of the king's game, there are particular laws, privileges, courts and officers, belonging to the king's forests. 1 Black. 279.

The forest courts are, the courts of attachments, of regard, of swainmote, and of justice seat.

The court of attachments is to be held before the verderers of the forest, once in every forty days, to inquire of all offenders against the king's deer, or covert for the game, who may be attached by their bodies, if found in the very act of transgression, otherwise by their goods; and in this court the forests are to bring in their attachment, or presentments of vert and venison: and the verderers are to receive the same, and to enroll them, and to certify them under their seals, to the court of justice seat, or swainmote, for this court can only inquire of but not convict offenders.

The court of regard or survey of dogs is be holden every third year, for the lawing or expeditating of mastiffs, which is done by cutting of the claws of the forefeet, to prevent them from running after deer. No other dogs than mastiffs were permitted to be kept within the king's forests, it being supposed that the keeping of these, and these only, was necessary for the defence of a man's house.

The court of swainmote is to be holden before the verderers as judges, by the steward of the swainmote, thrice in every year, the swains or freeholders within the forest composing the jury. The jurisdiction of this court, is, to inquire into the oppressions and grievances committed by the officers of the forest, and to receive and try presentments certified from the court of attachments, against the offenders in vert and venison; and this court may not only inquire, but convict also, which conviction shall be certified to the court of justice seat, under the seals of the jury, for this court cannot proceed to judgment.

The court of justice seat, is the principal court; which is held before the chief justice in eyre, or chief itinerant judge, or his deputy, to hear and determine all trespasses within the forest, and all claims of franchises, liberties, and privileges, and all pleas and causes whatsoever therein arising. It may also proceed to try presentments made in the inferior courts of the forest, and to give judgment upon the convictions that have been made in the swainmote courts. It may be held every third year. This court may fine and imprison, it being a court of record: and a writ of error lies to the court of king's bench. 1 Black. 289. 2 Black. 38. 3 Black. 71. But the

forest laws have long ago ceased to be put in execution. 1 Black. 289.

Forest-trees. The planting of forest-trees is profitable as well as pleasing and respectable; and a young planter may live to reap much reward from his labour, or he may leave a valuable inheritance to his children. "The plantation and care of timber is like buying the reversion of an estate; for a little money expended, we become heirs to great sums. In countries scarce of firing, and where poles and rails are wanted, underwood will pay the proprietor triple more in value than the best fields of corn, and the oaks among it remain a great estate to succeeding generations." Poor land, that does not for corn, would be profitably cultivated in wood; but such ground should be sown, rather than planted. Wet places may be advantageously planted with the amphibious tribe, as willow, sallow, withy, osier, &c.

For those who may be disposed to plant forest-trees, the following directions are offered: The manual work proper to this business, is nearly the same as for fruit-trees and shrubs; and though plantations of forest-trees need not be so nicely attended to as fruit-trees, yet the better the work is performed, the fairer is the prospect in growing good timber: a check by an error at first planting is a loss of time, and a damage done to trees which is sometimes never recovered. To give an instance: the mould is often thrown on the root of a forest-tree in lumps, when if a little sifted earth was used, so as just to cover them with fine mould, the trouble would be amply repaid by the quick striking, and future strength of the tree.

Ground designed for planting should be prepared as long as it can beforehand, by the use of the plough or spade; and if some sort of previous cultivation, either in corn or vegetables, was adopted, the soil would be better fitted to receive the trees. At any rate, the places where the trees are to be set, should be previously dug somewhat deep, and cleared of rubbish, perennial weeds, tcouch, &c. If wet, let it be properly drained, for none but aquatics can do well in a cold and very moist soil.

In open planting for timber, to make only the holes good where the trees are set, is sufficient, if the soil is not strong (which generally speaking however it should be); and in such plantations the plough being used for corn, or some sort of crop to be carried off, the whole soil will be prepared for the trees' roots to spread. A plantation of this sort may be constantly under the plough, till the trees shade too much; and then it may be sown down for grass, which lying warm, and coming early, would be found useful. The opportunity given to improve a soil by this cultivation, would insure very fine timber.

But a plantation of trees being made (as suppose of oaks) at due distances, and the ground ploughed for two or three years, while they got a little ahead, then it might be sown profitably, with nuts, keys, and seeds for underwood, observing to thin the plants the second year, and again the third, till two or three feet asunder in poor ground, and to three or four feet distance if rich. In fourteen or fifteen years (or much sooner for some purposes), the ash-poles, &c. will be fine, and meet with a ready sale as useful stuff: afterwards the underwood will be fit to cut, in a strong state, every eleven or twelve years. In the management of underwood, some have thinned the plants while young, to three feet asunder, and cut them down at three years, to about six inches, in order to form stools, which in about ten years are cut, having produced several stems from each. Some persons have cut seedling trees down at this age to three inches for timber, leaving only one strong shoot to grow from each stool; and thus finer trees are frequently (or rather certainly) produced, than from seedlings not cut down.

The distances of the timber-plants, may be from twenty-five to thirty-five feet, according to the soil, or opinion of the planter. If no view to underwood, the above open planting may be made close, by setting first the principals (which should be fine plants), and then filling up with others that are worse, to within about eight or nine feet of one another. They will at this distance come to fair timber, or may be thinned at pleasure; and even among these, a small crop of underwood might be had which would shelter the timber-plants, and help to draw them up straight.

As to little plantations, of thickets, coppices, clumps, and rows of trees, they are to be set close according to their nature, and the particular view the planter has, who will take care to consider the usual size they attain, and their mode of growth. An advantage at home for shade or shelter, and a more distant object of sight, will make a difference. For some immediate advantage, very close planting may take place, but good trees cannot be thus expected; yet if thinned in time, a straight tall stem is thus procured, which afterwards is of great advantage.

For little clumps or groups of forest-trees (as elms), these may be planted three or four in a spot, within five or six feet of one another, and thus be easily fenced; having the air freely all round, and a good soil, such clumps produce fine timber.

Single trees of every sort grow off apace, and are more beautiful than when in the neighbourhood of others, and particularly firs, pines, larches, limes, walnuts, and chesnuts: the edible fruited chesnut is exceedingly good for timber; but the horse is only ornamental, flourishing most on high dry ground. As to rows of trees, whether single or double, when planted for a screen, they may be set about seven or eight feet asunder, upon an average, according to their nature, taking care to prune them occasionally, from too galling an interference.

Avenues are now seldom planted; but when they are, two good rows of elms, limes, chesnuts, &c. should be set at the width of the house, at full thirty feet distance in the rows: to thicken which, intermediate plants may be set; and also an inner row, to be removed when the principal trees are full grown. Avenues to prospects should be fifty or sixty feet wide.

The best season for planting the deciduous kinds of forest-trees, is toward the end of October, and for evergreen sorts, the end of March; though the soil, whether light and dry, or heavy and wet, should somewhat direct; evergreen trees being to be planted generally with safety, early in autumn, if the soil is warm; but in all cases trees should be planted in dry weather, that the mould may be loose to drop in, and lie close between the roots, which is a material thing: trees planted in rain or mists, are injured by the moisture moulding the roots.

Forest-trees for planting are generally preferred rather large, and being so, should not be taken up carelessly, but with as much of an uninjured spread of roots as possible; yet free-growing plants of about three or four feet high, promise in the end to make finer trees than those that are planted larger. Some say they are best at this size from the seed-bed; and others, to have been once planted out, having had their tap roots then cut: and generally speaking this is the case, as they have a more bushy and horizontal root.

In the act of planting, let every thing be done as for fruit-trees; *i. e.* the hole dug wide and deep, the ground well broken, or rather sifted, to lie immediately about the roots, &c. Let the trees be made fast by stakes, and litter laid about their roots to keep out frost and drought. It is of much consequence to take care that the roots (especially of evergreen trees) do not get withered before planted. Evergreens do best in a dry, but deciduous forest-trees (generally) in a moist soil, if it is not wet. Oaks, in particular, though at first they may appear to do poorly, grow well in strong moist ground, and make the best timber.

Fencing is the last thing to be considered. If trees are planted where cattle go, their stems must be protected from barking and rubbing. The common way of small posts and little rails is well known; but if large cattle are not led where the trees are, good thorns stuck round them, and tied to them, are sufficient, and indeed this might do in almost all cases. There are various ways, ordinarily known; but whatever mode is used, let it be at first well executed, and afterwards repaired in time, as often as there is need.

Whoever plants forest-trees, should take care to dress them by proper pruning, and suffering no suckers to remain about their roots. The tops should be kept equal, and not permitted to spread too much in heavy branches, but trained in a light and spiral way, always preserving the leading shoot, to encourage mounting, which is the perfection of a forest-tree. The stems of all trees designed for timber, should be constantly and timely attended to, as it is necessary to rub off buds, or to cut off the side shoots, except here and there a small one, which may serve to detain the sap to the swelling of the trunk; but branches being left on of any strength, keep the tree from mounting, and draw it crooked; and such branches, if cut off when large, occasion knots, and sometimes a decay at the part.

Plantations growing thick should be thinned in time, but not too much at once, especially in hilly situations; for those trees which remain, come suddenly to be exposed (after having been brought up under the shelter of others), and suffer much; getting crooked, stunted, and bushy, instead of having their desirable erect form, without which they are not adapted for superior uses, or agreeable to the eye.

Ornamental trees, as the crab, black cherry, mountain ash, &c. may prove profitable, as well as agreeable, here and there one amongst forest-trees, and should therefore not be omitted: the wood is good.

FORE-STAFF, or CROSS-STAFF, an instrument used at sea for taking the altitude of the sun, moon, or stars. It is called fore-staff, because the observer, in using it, turns his face towards the object; whereas in using Davis's quadrant, the back of the observer is towards the object; and hence its denomination of back-staff. See INSTRUMENTS ASTRONOMICAL.

FORESTALLING, is the buying or bargaining for any corn, cattle, or other merchandize, by the way, before it comes to any market or fair, to be sold; or by the way, as it comes from beyond the seas, or otherwise, towards any city, port, haven, or creek, of England, to the intent to sell the same at a higher price.

At the common law, all endeavours to enhance the price of any merchandize, and all practices which have an apparent tendency thereto, whether by spreading false rumours, or by purchasing things in a market before the accustomed hour, or by buying and selling again the same thing in the same market, or by any such-like devices, are highly criminal, and punishable by fine and imprisonment. 1 Haw. 234.

Several statutes have from time to time been made against these offences in general, which were repealed by 12 Geo. III. c. 71.

But though these offences are no longer combated by the statutes, they are still punishable upon indictment at the common law, by fine and imprisonment.

FORESTER, a sworn officer of the forest, appointed by the king's letters patent, to walk the forest at all hours, watch over the vert and venison; also to make attachments and true presentments of all trespasses committed within the forest.

FORFEITURE, is a punishment annexed by law, to some illegal act or negligence in the owner of lands, tenements, or hereditaments, whereby he loses all his interest therein, and they go to the party injured, as a recompense for the wrong which either he alone or the public together with him have sustained. 2 Black. 267.

The offences which induce a forfeiture of lands and tenements, are principally the following: treason, felony, misprison of treason, præmunire, drawing a weapon on a judge, striking any one in the presence of the king's court of justice, and popish recusancy, or non-observance of any certain laws enacted in restraint of papists.

By the common law, all lands of inheritance of which the offender is seised in his own right, and also all rights of entry to lands in the hands of a wrong-doer, are forfeited to the king on an attainder of high treason, although the lands are holden of another; for there is an exception in the oath of fealty, which saves the tenant's allegiance to the king; so that if he forfeits his allegiance, even the lands he held of another lord are forfeited to the king, for the lord himself cannot give of lands but upon that condition. Co. Lit. 8.

Also upon an attainder of petit treason or felony, all lands of inheritance of which the offender is seised in his own right, as also all rights of entry to lands in the hands of a wrong-doer, are forfeited to the lord of whom they are immediately holden: for this by the feudal law was deemed a breach of the tenant's oath of fealty in the highest manner; his body with which he had engaged to serve the lord being forfeited to the king, and thereby his blood corrupted, so that no person could represent him; and all personal estates, whether they are in action or possession, which the party has or is entitled to, in his own right, and not as executor or administrator to

another, are liable to such forfeiture in the following cases:

1st. Upon a conviction of treason or felony. But the lord cannot enter into the lands, holden of him upon an escheat for petit treason or felony, without a special grant, till it appears by due process that the king has had his due prerogative of the year, day, and waste. Stamf. P. C. 191.

As to forfeiture of goods and chattels, it seems agreed that all things whatever, which are comprehended under the notion of a personal estate, are liable to such forfeiture.

2nd. Upon a flight found before the coroner, on view of a dead body.

3d. Upon an acquittal of a capital felony, if the party is found to have fled. 2 Haw. 450.

4th. If a person indicted of petit larceny and acquitted is found to have fled for it, he forfeits his goods as in cases of grand larceny. 2 Haw. 451. But the party may in all cases, except that of the coroner's inquest, traverse the finding of the flight; and it seems agreed that the particulars of the goods found to be forfeited may also be traversed.

5th. Upon a presentment by the oaths of twelve men, that a person arrested for treason or felony fled from, or resisted, those who had him in custody, and was killed by them in the pursuit or scuffle. Id.

6th. If a felon waive, that is, leave any goods in his flight from those who either pursue him, or are apprehended by him so to do, he forfeits them, whether they are his own goods, or goods stolen by him; and at common law, if the owner did not pursue and appeal the felon he lost the goods for ever: but by 21 H. VIII. c. 11, for encouraging the prosecution of felons, it is provided, that if the party comes in as evidence on the indictment, and attaints the felon, he shall have a writ of restitution. 4 Inst. 134.

7th. If a man is felo de se, he forfeits his goods and chattels. 5 Co. 109.

8th. A convict within clergy forfeits all his goods, though he may be burnt in the hand; yet thereby he becomes capable of purchasing other goods. But, on burning in the hand, he ought to be immediately restored to the possession of his lands. 2 H. 388, 389.

The forfeiture upon an attainder of treason or felony shall have relation to the time of the offence for the avoiding all subsequent alienation of the lands; but to the time of conviction, or fugam fecit found, &c. only as to chattels, unless the party was killed in flying from, or resisting those who had arrested him: in which case it is said that the forfeiture shall relate to the time of the offence. Plowd. 488.

Forfeiture *in civil cases.* A forfeiture of copyhold by selling timber was relieved in equity; but the lord-keeper declared, that in case of a wilful forfeiture he would not relieve. Chan. Cas. 96. In case of a forfeiture equity can relieve, where they can give satisfaction. 1 Salk. 156.

Forfeiture *of marriage*, a writ which anciently lay against him, who by holding knight's service, and being under age, and unmarried, refused her whom the lord offered him without his disparagement, and married another. F. N. B. 141.

FORFICULA, *earwig*, an insect of the coleoptera order. The generic character is, antennæ setaceous; wing-sheaths halved; wings covered; tail forcipated. This is not a numerous genus. The forficula auricularia, or common earwig, is an insect so familiarly known, that a formal description might seem unnecessary: its structure, however, is highly curious, and its natural history well worthy of particular observation. The wings of this insect are remarkably elegant, and are convoluted beneath their small sheaths in so curious a manner that they cannot be viewed without admiration: they are very large in proportion to the animal, transparent, and slightly iridescent. The earwig flies only by night, and it is not without great difficulty that it can be made to expand its wings by day: it is even probable that they would receive injury by any long exposure to the diurnal air; the animal therefore keeps them completely covered; and indeed so unusual a circumstance is it to see them expanded, that sir Thomas Brown, in his Pseudodoxia Epidemica, has thought it necessary to confute the commonly received opinion, that the earwig is an "impennous insect."

The female earwig deposits her eggs, which are rather large for the size of the animal, of a white colour, and of an oval shape, under stones, or in any damp situation, where they may be secure from too much heat or drought. From these eggs are hatched the young larvæ, which are at first very small, but have very much the general aspect of the parent animal, except that they are of a white or whitish colour, and that the limbs of the forceps at the tip of the abdomen are not yet curved inwards. The parent insect, according to the observations of Degeer, guards and broods over her young nearly in the same manner as a hen does over her chickens; and they generally remain close to the sides, or under the abdomen of the parent, for several hours in the day. They change their skin at certain intervals during the earlier stages of their growth; and after each change acquire a darker colour and a greater degree of resemblance to the full-grown insect; till at length the wing-sheaths and wings are formed, and the animals may be considered as perfect.

The usual food of the earwig consists of decayed fruit, and other vegetable substances; and it does not seem to be naturally carnivorous, though, if kept without proper nourishment, it will, like many other animals, occasionally attack and even devour its own species.

The popular dread in which this insect is held, on a supposition of its sometimes entering the cavity of the ear, and piercing the tympanum, is considered by some as problematical, though we believe there are instances of earwigs, which naturally creep into holes and apertures of every kind, having accidentally taken shelter in the ears of persons asleep, and occasioning great pain. The best means of expelling them, we have heard, is to drop a small quantity of brandy or other spirit into the ear.

FORGE, properly signifies a small furnace, in which smiths and other artificers of iron or steel, &c. heat their metals red-hot, in order to soften and render them more malleable and manageable on the anvil.

The forge used by the several operators in iron is very simple: we shall instance that of the blacksmiths,

to which all the rest are reducible, the construction of which is as follows. The hearth or fireplace of the forge is to be built up from your floor with brick, about two feet and a half, or sometimes more, according to the purpose you design to forge for: if your forge is intended for heavy work, your hearth must lie lower than it need be for light work: the forge may be of what breadth is thought convenient. It may be built with hollow arches underneath, to set several things out of the way: the back of it is built upright to the top of the ceiling, and inclosed over the fireplace with a hovel, which ends in a chimney to carry away the smoke. In the back of the forge, against the fireplace, is fixed a thick iron plate, with a taper pipe in it, about five inches long, which pipe comes through the back of the forge. Into this taper pipe is placed the nose or pipe of the bellows: the office of this is to preserve the pipe of the bellows and the back of the forge about the fireplace, from burning. Right before the back is placed, at about two feet distance, the trough, which reaches commonly the whole breadth of the forge, and is as broad as is thought necessary. The bellows is placed behind the back of the forge, having one of its boards so fixed, that it can neither move upwards nor downwards. At the ear of the lower board is fastened a rope or chain, which reaches up to the rocker, and is fastened there to the further end of the handle. This handle is fastened across a rock-staff, which moves between two cheeks upon the centre pins, in two sockets; so that by drawing down this handle the moving board of the bellows rises; and by a considerable weight set on the top of its upper board, sinks down again, and by this agitation performs the office of a pair of bellows.

Forge is also used for a large furnace, in which iron ore, taken out of the mine, is melted down; or it is more properly applied to another kind of furnace, where the iron ore, melted down and separated in a former furnace, and then cast into sows and pigs, is heated and fused over again, and beaten afterwards with large hammers, and thus rendered more soft, pure, ductile, and fit for use.

Of these there are two kinds: the first is called the finery, where the pigs are worked into gross iron, and prepared for the second, which is called the chafery, where it is further wrought into bars fit for use.

FORGERY, is where a person counterfeits the signature of another with intent to defraud, which by the law of England is made a capital felony.

A receipt to a cash memorandum is not a receipt on acquittance for the payment of money within 2 Geo. II. c. 25, against forgery.

Forgery may be committed by making a mark in the name of another person. It may also be committed in the name of a person who had never had existence. And it may be committed of an instrument, though such an instrument as the one forged does not exist either in law or fact.

Indorsing a real bill of exchange with a fictitious name is forgery; although the use of a fictious name was not essential to the negotiation.

A forged bank-note (although the word pounds is omitted in the body of it), and there is no water-mark in the paper, is a counterfeit note for the payment of money.

Altering an entry of money received, made by a cashier of the bank, in the bank-book of a person keeping cash there, by prefixing a figure to increase the amount of the sum received, is forging a receipt for money.

A receipt indorsed on a bill of exchange in a fictitious name is forgery, although such name does not purport to be the name of any particular person.

If a person who has for many years been known by a name which was not his own, and afterwards assume his real name, in that name draws a bill of exchange, he will not be guilty of forgery, although such bill was drawn for fraudulent purposes.

If any person shall falsely make, forge, or counterfeit, or cause or procure to be falsely made, forged, or counterfeited, or willingly aid or assist in the false making or counterfeiting, any deed, will, bond, writing obligatory, bill of exchange, promissory note for payment of money, acquittance, or receipt, either for money or goods, with intent to defraud any person; or shall utter or publish the same as true, knowing the same to be false, forged, or counterfeited, he shall be guilty of felony without benefit of clergy; but not to work corruption of blood, or disherison of heirs. 2 Geo. II. c. 25.

Forging or imitating stamps to defraud the revenue is forgery by the several stamp acts; and the receiving of them is made single felony, punishable with seven years transportation. 12 Geo. III. c. 48.

FORGING, in smithery, the beating or hammering iron on the anvil, after having first made it red-hot in the forge, in order to extend it into various forms, and fashion it into works.

There are two ways of forging and hammering iron; one is by the force of the hand, in which there are usually several persons employed, one of them turning the iron and hammering likewise, and the rest only hammering. The other way is by the force of a water-mill, which raises and works several huge hammers beyond the force of man; under the strokes of which the workmen present large lumps or pieces of iron, which are sustained at one end by the anvils, and at the other by iron chains fastened to the ceiling of the forge.

This last way of forging is only used in the largest works, as anchors for ships, &c. which usually weigh several thousand pounds. For the lighter works, a single man serves to hold, heat, and turn with one hand, while he hammers with the other.

Each purpose the work is designed for requires its proper heat; for if it is too cold, it will not feel the weight of the hammer, as the smiths call it, when it will not batter under the hammer; and if it is too hot, it will redsear, that is, break or crack under the hammer.

The several degrees of heats the smiths give their irons, are, first, a blood-red heat; secondly, a white flame heat; and, thirdly, a sparkling or welding heat.

FORISFAMILIARI. A son is properly said to be forisfamiliari when he accepts of his father's part of his lands, and is contented with it in the life-time of his father, so that he cannot claim any more.

FORM, *printer's*, an assemblage of letters, words and lines, ranged in order, and so disposed into pages by the compositor; from which, by means of ink and a press, the printed sheets are drawn. Every form is inclosed in an iron chase, wherein it is firmly locked by a number

of pieces of wood; some long and narrow, and others of the form of wedges. There are two forms required for every sheet, one for each side; and each form consists of more or fewer pages, according to the size of the book. See PRINTING.

FORM *of a series*, in algebra, that affection of an undeterminate series, which arises from the different values of the indices of the unknown quantity.

FORM, is required in law proceedings, otherwise the law would be no art; but it ought not to be used to ensnare or entrap. Hob. 232. The formal part of the law, or method of proceeding, cannot be altered but by parliament: for if once those outworks were demolished, there would be an inlet to all manner of innovation in the body of the law itself. 1 Black. 142.

FORMA PAUPERIS, is when any person has cause of suit, and is so poor that he cannot support the usual charges of suing at law or in equity. In this case, upon his making oath that he is not worth five pounds his debts being paid, and bringing a certificate from some lawyer that he has just cause of suit, the judge admits him to sue in forma pauperis, that is, without paying fees to counsellor, attorneys, or clerk; and he shall have original writs and subpœnas gratis. 11 H. VII. c. 12.

And he shall when plaintiff be excused from costs, but shall suffer other punishment at the discretion of the judge. And it was formerly usual to give such paupers, if nonsuited, their election either to be whipped or pay the costs, though the practice is now disused. 3 Black. 400.

It seems agreed that a pauper may recover costs, though he pay none; for although the counsel and clerks are bound to give their labour to him, yet they are not bound to give it to his antagonist. Id.

FORMEDON, in law, a writ that lies for a person who has a right to lands or tenements, by virtue of any entail, arising from the statute of Westm. 2 Ch. II.

This writ is of three kinds, viz. a descender, remainder, and reverter. Formedon in descender lies where a tenant entail infeoffs a stranger, or is disseised and dies, the heir may bring this writ to recover the land. Formedon in remainder lies where a man gives lands, &c. to a person in tail, and for default of issue of his body, the remainder to another in tail: here if the tenant in tail dies without issue, and a stranger abates and enters into the land, he in remainder shall have this writ. Formedon in reverter lies where lands are entailed on certain persons and their issue, with remainder over for want of issue, and on that remainder failing, then to revert to the donor and his heirs: in this case, if the tenant in tail dies without issue, and also he in remainder, the donor and his heirs, to whom the reversion returns, may have this writ for the recovery of the estate, though the same be aliened, &c. Writs of formedon are now scarcely ever brought, the title to lands being commonly tried upon an ejectment.

FORMIC ACID, in chemistry, an acid that exists abundantly in the formica rufa, or red ant. The existence of this acid was first made known by Mr. Ray, in a correspondence with Dr. Hulse. The doctor informed him that these insects, when irritated, give out a clear liquid, which tinges blue flowers red: a fact which had been observed by others. Hence it was found to be an acid, which was obtained by bruising the insects, by distilling them, and by infusing them in water. The French chemists obtained the acid by bruising ants, and macerating them in alcohol. When the alcohol was distilled over, an acid liquor remained, which saturated with lime, mixed with sulphuric acid, and distilled, yielded a liquid that possessed all the properties of acetic acid. This acid was formerly considered as possessing peculiar properties, and then denominated formic acid; but it has lately been ascertained to consist of a mixture of acetic and malic acids.

FORMICA, *ant*, an insect of the hymenoptera class. The generic character is, head large, with diffracted filiform antennæ; mouth with large jaws, and four unequal feelers; thorax narrowed behind, and furnished with an upright scale; abdomen subglobose; males and females winged; neutrals apterous; females and neutrals furnished with a concealed sting. According to Linnæus there are 18 species. The insects of this genus live in large societies, somewhat in the manner of bees and wasps, and are like them divided into males, females, and neutrals, which latter constitute the great or general assortment, and appear to conduct the business of the nest, which is usually placed at a small distance from the surface in some slight elevation either prepared by the insects themselves, or previously formed by some other animals, as moles, &c. They feed both on animal and vegetable substances, devouring the smaller kinds of insects, caterpillars, &c. as well as fruits of different kinds. They are particularly attracted by sweets; and for this reason they ascend such trees as are infested with aphides, in order to obtain the saccharine substance discharged by those animals; and hence seems to have arisen the idea of their enmity against the genus aphis. Some species of ants are furnished with a sting, while others are destitute of that part.

The largest of the European ants is the formica herculanea, or great wood-ant, of a chesnut colour, with the abdomen measuring two lines or more in length. This species is chiefly found in dry woods of pine or fir, where it inhabits a large conical nest or hillock, composed of dry vegetable fragments, chiefly of fir-leaves: the nest is internally distributed into several paths or tubes, converging towards the central part, and opening externally: in the middle or centre reside the young, or larvæ, which are nursed by the neutral ants, and are occasionally brought to the surface, in order to be more within the influence of the air and sunshine for a certain time, after which they are again conveyed to the bottom or centre. When full-grown, they envelop themselves in oval, white, silken cases, in which they undergo their change into chrysalis, and at length emerge in their complete form. The males and females are winged, and the females are much larger than the males.

The common or black ant, formica nigra Lin. is a well-known inhabitant of our fields and gardens, residing in great numbers beneath mole-hills and other elevated spots. It is of a brownish-black colour, and of a glossy or polished surface. The eggs of this species are deposited early in the spring, and are extremely small, and of a white colour. From these are hatched the larvæ, which are of a thickish form, destitute of legs, and somewhat resemble in miniature the maggots of wasps and bees. They are carefully nourished by the neutral or labouring ants till they are arrived at their full growth, when they enclose themselves in smooth, oval, pale-yel-

low, silken webs or cases, in which state they are popularly known by the mistaken title of ant-eggs; the real eggs, as before observed, being white, and extremely small. It is generally in the months of June and July that the larvæ thus enclose themselves. The chrysalis, if taken out of its silken case, is of a white colour, and exhibits all the limbs of the future animal in an imperfect or contracted state. During the time of their remaining as chrysalis, the neutral ants attend them with the same care as when in their larva state, frequently shifting their situation, and placing them at greater or smaller elevations, according to the different state of the atmosphere. This care of the ants in conveying their pupæ from place to place, seems to have been often mistaken for a sedulous industry in collecting grains of wheat, which the pupæ, on a cursory review much resemble.

About the beginning of August the males and females may be observed in the nests: these differ from the neutrals in being furnished with wings, and the female is far larger than the male, the body equalling in size that of the common window-fly, and the upper wings being very long and large. At this time of the year the males and females emigrate in vast numbers; sometimes flying at a considerable height, and sometimes creeping along the surface. It is not uncommon to see them enter houses at this period, attracted by sweets in particular, either moist or dry. After the breeding season the males live but a very short time, and the females return to their nests in order to deposit their eggs. During the winter this species, like the rest of the European ants, remains in a state of torpor, without laying up provisions for that season, as erroneously supposed; and during the spring emerges from its concealment, and recommences its labours.

Ants feed both on animal and vegetable substances of various kinds. Their addiction to animal substances is often turned to good account by anatomists, who, when they wish to obtain the skeleton of any animal too small or delicate to admit of being prepared the usual way, dispose the animal in a proper position in a small box, with perforations in the lid, and deposit it in a large ant-hill; in consequence of which, after a certain space, the whole of the softer parts are eaten away by these insects, and the skeleton remains in its proper position. It is thus that very elegant skeletons of frogs, snakes, &c. may be obtained.

This addiction to animal food in the insects of the genus formica can hardly be said to be productive of any mischief in the European regions; but in various parts of America and the West Indian islands the ravages committed by ants are incredible. One of the chief of these destroyers is the formica omnivora of Linnæus, a very small species, of a brown or chesnut colour: it is extremely voracious, attacking every animal substance to which it can gain access. It occurs in various parts of Africa as well as in America and in the West Indies; and it is said to be so numerous in some districts, that a deer, hog, &c. being killed, and left on the ground by night, will by the next morning have the flesh entirely cleared from the bones, and be reduced to a complete skeleton.

The formica rufa is black; thorax compressed; and with legs ferruginous. See Plate LX. Nat. Hist. fig. 208.

FORRAGE, in the military art, denotes hay, oats, barley, wheat, grass, clover, &c. brought into the cam by the troopers for the sustenance of their horses.

FORSKOHLEA, a genus of the pentagynia order, in the decandria class of plants. The calyx is pentaphyllous, and longer than the corolla. There are ten petals spatulated, *i. e.* roundish before, with a linear base. There are three species, two of them annuals, natives of Egypt, the Cape, and Teneriffe.

FORSTERA, a genus of the triandria order, in the gynandria class of plants. The perianthium is double; the exterior one beneath, three-leaved; the interior one above, and six-cleft; the corolla tubular. There is one species, an herbaceous plant of New Zealand.

FORT, in the military art, a small fortified place, environed on all sides with a moat, rampart, and parapet. Its use is to secure some high ground, or the passage of a river, to make good an advantageous post, to defend the lines and quarters of a siege, &c.

Forts are made of different figures and extents, according as the ground requires. Some are fortified with bastions, others with demi-bastions. Some again are in form of a square, others of a pentagon. A fort differs from a citadel, as this last is built to command some town. See FORTIFICATION.

FORTIFICATION, may be defined the science of military architecture; and when applied to a city, town, or other place, it consists in the art of putting any of these in such a posture of preparation, by means of ramparts, parapets, ditches, and outworks, that each individual part defends, and is defended by, some other parts, so that a small number of men can hold out for a considerable time against a multitude.

When scattered families, abandoning a wandering and pastoral life, settled in communities for mutual support, and built towns for common advantage, it became necessary to think of the means of defence: the trunks and branches of trees, and then walls and ditches, rudely constructed, were accordingly the first elements of fortification; and as the art of war was also in its infancy, these were sufficient to defeat hasty attacks, and prevent sudden incursions. At length offensive weapons were invented; and as the assailants had thus acquired a decided advantage, it became necessary to employ new means to frustrate them. Loop-holes, through which the arrows of the besieged might be directed with almost unerring certainty, were accordingly recurred to; and at length square towers were made to project from the walls, so as to enable the men placed within them to scour the ditches and defend the walls. In the progress of improvement the outer line of these quadrangular masses was made to assume a curvilinear direction; and at the present day there still remain numerous traces of this mode in all the ancient castles in the kingdom.

But as the science advanced towards perfection new advantages were obtained; and instead of presenting a large semicircular portion of masonry to the enemy, an angle only was projected, and such a fortunate disposition of the works thereby produced, that no part could be attacked with impunity. In process of time ramparts were added; and the ancient towers, which had been changed into bastions, were provided with ravelins, horn-works, and outworks of all kinds, so as to resist the violence of cannon and mortar batteries; and defy, at least

for a time, the efforts of the besiegers, provided with all the various implements of modern warfare.

Fortification is either regular or irregular. The regular is that built in a polygon, the sides and angles of which are all equal, being commonly about a musket-shot from each other. Irregular fortification, on the contrary, is where the sides and angles are not uniform, equidistant, or equal.

I. Of regular Fortification.

Authors in general agree as to the form, but they differ in respect to the construction of the parts. The chief of those who have written on this art, are Pagan, Blondel, Vauban, Coehorn, Scheiter, and Muller: in addition to these the names of Robins, Belidor, Folard, le Blond, marshal Saxe, Tielke, and Belair, ought also to be enumerated, as they have greatly contributed to the general knowledge of the science.

It must be constantly recollected by every engineer, that his views are not to be confined to the mere art of fortification. He must be able to take advantage of natural strength and position. Chains of mountains and streams of water, together with the influence of climate, should constitute a part of the natural system to which he should direct his application.

According to count Pagan, fortification consists of three different sorts, viz. the great, the mean, and the little, the principal dimensions of which are contained in the following Table.

	The Great Fortification.		The Mean.		The Little.	
	For Squares.	For all other Polygons	For Squares	For all other Polygons	For Squares	For all other Polygons
Exterior side	200	200	180	180	160	160
The perpendicular	27	30	24	30	21	30
The face -	60	60	55	55	45	50
The flank -	22	24-2	19-1	24	18-3	23-2
The curtin -	73-2	70-5	63-4	60-4	63-5	50-4
The line of defence	141-4	141-2	126-1	126-5	115-5	112-3

Blondel fortifies within the given polygon: he establishes two sorts of fortification; the great one, whose exterior side is 200 toises, and the lesser one, 170; because he will not have the line of defence exceed 140 toises, which is the greatest musket-shot, nor less than 120 toises, not to increase the number of bastions. He begins by the diminishing angle, which may be found by taking 90 degrees from the angle of the polygon, and by adding 15 degrees to the third of the remainder.

Vauban's method is divided into little, mean, and great; the little is chiefly used in the construction of citadels; the mean, in that of all sorts of towns; and the great, in particular cases only.

	Forts.						Little.				Mean.		Great.	
Side of polygon	80	90	100	110	120	130	140	150	160	170	180	190	200	260
Perpendicular	10	11	12½	14	15	16	20	21	23	25	30	31	25	22
Faces bastion	22	5	28	30	33	35	40	42	45	47	50	53	55	60
Cap. of ravel.	25	28	30	35	38	40	45	50	50	52	55	55	60	50

In the first vertical column are the numbers expressing the lengths of the exterior sides from 80 to 260.

In the second, the perpendiculars answering to these sides.

In the third, the lengths of the faces of the bastions; and in the fourth, the lengths of the capitals of the ravelins.

Belidor's method is divided also into little, mean, and great; and in all three the exterior side is 200 toises; the perpendicular of the little is 50, that of the mean 55, and the great 40; the faces of the first 70, the second 70, and the third 55 toises.

Scheiter's method is divided into the great, mean, and small sort. The exterior side of the polygon for the great sort is 200 toises, the mean sort 180, and the small 160. The line of defence in the first is 140 to toises, the second 130, and the third 120. This line is always razant. All the other lines are fixed at the same length for all poly-

gons, whose structure chiefly depends upon the knowledge of the exterior side, of the capital, or of the flanked angle, the rest being easily finished.

TABLE of CAPITALS and FLANKED ANGLES.

Capital for the small sort	39	41½	42½	45	46	47½	48½	50	50½

Errard, of Bois-le-Duc, who was employed by Henry IV. and was the first that laid down rules in France respecting the best method of fortifying a place so as to cover its flank, constructs that flank perpendicular to the face of the bastion; but by endeavouring to cover it effectually, he makes the gorges too exiguous, the embrazures too oblique, and leaves the ditch almost defenceless.

The chevalier de Ville, who succeeded Errard, draws the flank line perpendicular to the curtin; but here again the embrasures are too oblique, especially in the polygons, and the ditch is necessarily ill guarded. This engineer's method of fortifying is styled by most authors, the French method. His favourite maxim is, to make the flank angle straight, and the flank equal to the demigorge.

Count Pagan makes the flank perpendicular to the line of defence, which method seems to agree perfectly with this maxim, because by that means the flank so raised covers as much as possible the face of the opposite bastion; but notwithstanding this apparent advantage, the flank becomes too small, and is too much exposed to the enemy's batteries. This engineer acquired great reputation during the several sieges which he assisted in conducting under Louis XIII. His system has been improved upon by Alain Marrison Mallet, and his construction in fortification is to this day esteemed the most perfect. It differs very little from marshal Vauban's first system. Count Pagan has pointed out the method of building casements in a manner peculiar to himself.

Marshal Vauban has judiciously steered between these different methods. He has drawn his flank in such a manner, that it does not stand too much exposed, nor does its collateral line of defence extend too far from the direct line of defence. He has effected this by lengthening out his flank, and giving it a circular form.

It cannot be disputed that large and extensive flanks and demigorges are superior to narrow and confined ones. The more capacious the flank is, the better calculated will it prove for the disposition of a formidable train of artillery. From this conviction many writers, in their proposed system of fortification, have added a second flank, in order to augment the line of defence; but they did not foresee that this second flank is not only incapable of covering the face of the opposed bastion, except in a very oblique and insecure direction; but that the right flank or the flank of the bastion, is thereby more exposed to the enemy's batteries, which, it must be acknowledged on all sides, is a great fault.

The prevailing system of the present day is, to make the flanks of the bastion as wide as possible, without having recourse to a second flank, unless it be absolutely necessary. Those gorges are likewise best which are most capacious, because they afford space and ground in the bastion for the construction of entrenchments within, should the enemy have effected a practicable breach.

All parts of a fortification which stand exposed to the immediate attacks of a besieging enemy, must be strong enough to bear the boldest attempts, and the most vigorous impressions. This is a self-evident maxim, because it must be manifest to the most common understanding, that works are erected round a place for the specific purpose of preventing an enemy from getting possession of it. It consequently follows, that flanked angles are extremely defective when they are too acute, since their points may be easily flanked and destroyed by the besiegers' cannon.

The Dutch construct at sixty degrees; but according to Vauban's method, no work should be under seventy-five degrees, unless circumstances and situation should particularly require it.

The diagram annexed, together with the explanation that follows, will convey an idea of M. Vauban's method, in respect to the fortification of towns. See Plate LVI. Farriery, &c.

Inscribe in a circle a polygon of as many sides as the fortification is designed to have fronts; let AB, fig. 9, be one of the sides of half an hexagon, which bisect by the perpendicular CD; divide half of it AC into nine equal parts, and one of these into ten others; then these divisions will serve as a scale to construct all the parts of the fortification, and each of them supposed to be a toise or fathom, that is, six French feet; and therefore the whole side AB is supposed to be 180 toises. As the dividing a line into so many equal parts is troublesome and tedious, it is more convenient to have a scale of equal parts, by which the works may be constructed.

If therefore, in this case, the radius is taken equal to 180 toises, and the circle described with that radius being divided into six equal parts, or the radius being carried six times round, you will have an hexagon inscribed; AB being bisected by the perpendicular CD as before,

set off 30 toises from C to D, and draw the indifinite lines ADG, BDF; in which take the parts AE, BH, each equal to 50 toises; from the centre E describe an arc through the point H, meeting AD in G, and from the centre H describe an arc through the point E, meeting BD in F; or, which is the same, make each of the lines EG, HF, equal to the distance EH; then the lines joining the points A, E, F, G, H, B, will be the principal or outline of the front.

If the same construction be performed on the other sides of the polygon, you will have the principal or outline of the whole fortification. If, with a radius of 20 toises, there be described circular arcs from the angular points B, A, M, T, and lines are drawn from the opposite angles E, H, &c. so as to touch these arcs, their parts *ab*, *bc*, &c. together with these arcs, will present the outline of the ditch.

Definitions.

1. The part FEALN is called the bastion.
2. AE, AL, the faces of the bastion.
3. EF, LN, the flanks.
4. FG, the curtin.
5. FN, the gorge of the bastion.
6. AG, BF, the lines of defence.
7. AB, the exterior side of the polygon.
8. CD, the perpendicular.
9. Any line which divides a work into two equal parts is called the capital of that work.
10. *a*, *b*, *c*, the counterscarp of the ditch.
11. A, M, the flanked angles.
12. H, E, L, the angles of the shoulder, or shoulder only.
13. G, F, N, the angles of the flank.
14. Any angle whose point turns from the place is called saliant angle, such as A, M: and any angle whose point turns towards the place, re-entering angle, such as *b*, F, N.
15. If there be drawn two lines parallel to the principal or outline, the one at 3 toises distance, and the other at 8 from it, then the space *yx* included between the principal one and that farthest distant is called the rampart.

And the space *x*, contained by the principal line and that near to it, and which is generally stained black, is called the parapet.

16. There is a fine line drawn within four feet of the parapet, which expresses a step called banquette.

All works have a parapet of three toises thick, and a rampart of from 8 to 10, besides their slopes. The rampart is elevated more or less above the level of the place, from 10 to 20 feet, according to the nature of the ground, and the particular constructions of engineers.

The parapet is a part of the rampart elevated from 6 to $7\frac{1}{2}$ feet above the rest, in order to cover the troops which are drawn up there from the fire of the enemy in a siege; and the banquette is two or three feet higher than the rampart, or about four feet lower than the parapet; so that when the troops stand upon it, they may just be able to fire over the parapet.

17. The body of the place is all that which is contained within this first rampart; for which reason it is often said to construct the body of the place: which means, properly, the construction of the bastions and curtins.

18. All the works which are constructed beyond the ditch, before the body of the place, are called outworks.

II. Of irregular Fortification.

The most essential principle in fortification consists in making all the fronts equally strong, so that the enemy may find no particular advantage in attacking either of the sides. But this can only occur in a regular work, situated in a plain, or even ground; consequently there are but few places which are not irregular: and the great art here is, to remedy the defects and inconveniences occasioned by this circumstance.

If the situation to be fortified is an old town, inclosed by a wall or rampart, the engineer ought to consider well all the different circumstances of the figure, position, and nature of the ground, and to regulate his plan accordingly, so as to avoid as many disadvantages, on one hand, and to obtain as many advantages, on the other, as possible. If there is a rampart without towers, it must be decided whether bastions ought not to be added, and revelins and counter-guards constructed. Special care must be taken to make all the sides of the polygon nearly equal, and that the length of the lines of defence do not exceed the reach of musket-shot. Wherever the sides are inaccessible, either on account of a precipice, or marshy ground, they may be made much larger than those which are easy of access.

If the place to be fortified is new, and the situation will not admit of a regular construction, particular care must be taken to choose such a spot of ground as is most advantageous. All hills, or rising grounds, should be avoided, as these might command some parts of the works; marshes, because such situations are unwholesome, and lakes and standing waters for the same reason, except they can be rendered navigable.

Places built on mountains or rocks should never be large; for their use is generally to guard passes or inlets into a country, and it is difficult to provide for a large garrison under such circumstances. When fortifications are to be placed in the neighbourhood of the sea, for the purposes of protecting trade, the first thing to be considered is their situation, which ought to afford a good harbour for shipping. When M. Vauban fortified near rivers, he always made the exterior side next to the water much longer than any of the others; for as that part is not so liable to be attacked, great and manifest advantages were of course derived from this circumstance.

To illustrate this method of M. Vauban's, we shall give the plan of Hunninghen. That place was built for the sake of having a bridge over the Rhine, for which reason he made it only a pentagon; the side AB (fig. 10) next to the river is 200 toises, and each of the others but 180.

About the space *abc*, which lies before the front AB, is a stone wall: and the passages, are shut up with sluices, to retain the water in the ditches in dry seasons; and to prevent an enemy from destroying the sluice near the point *c*, whereby the water would run out and leave the ditches dry, the redoubt *y* was built in the little island hard by, in order to cover that sluice; without which precaution the place might be insulated from the river side, where the water is shallow in dry seasons.

The hornwork K, beyond the Rhine, was built to cov-

er the bridge; but as this work cannot be well defended across the river, the hornwork H was made to support the other.

Before finishing the description of this plan, we shall show how to find the long side AB. After having inscribed the two sides GE, GF, in a circle, draw the diameter CD, so as to be equally distant from the line joining the points EF that is parallel to it. On this diameter set off 100 toises on each side of the centre; from these points draw two indefinite perpendiculars to the diameter; then if from the points, EF, as centres, two arcs are described with a radius of 180 toises, their intersections A and B, with the said perpendiculars, will determine the long side AB, as likewise the other two FB and EA. In like manner may be found the long or short side of any polygon whatsoever.

When a place near a river is to be fortified for the safety of commerce, particular care should be taken in leaving a good space between the houses and the waterside, to have a quay or landing-place for goods brought by water; it should also be contrived to have proper places for ships and boats to lie secure in stormy weather, and in time of a siege; and as water-carriage is very advantageous for transporting goods from one place to another, as likewise for bringing the necessary materials, not only for building the fortifications, but also the place itself, the expenses will be lessened considerably when this convenience can be had; for which reason places should never be built any where but near rivers, lakes, or the sea, excepting in extraordinary cases, where it cannot be avoided.

The principal maxims of fortification are these, viz.

1. That every part of the works be seen and defended by other parts, so that the enemy cannot lodge any where without being exposed to the fire of the place.

2. A fortress should command all places round it; and therefore all the outworks should be lower than the body of the place.

3. The works furthest from the centre should always be open to those that are nearer.

4. The defence of every part should always be within the reach of musket-shot, that is, from 120 to 150 fathoms, so as to be defended both by ordnance and small fire-arms; for if it is only defended by cannon, the enemy may dismount them by the superiority of their own, and then the defence will be destroyed at once; whereas, when a work is likewise defended by small-arms, if the one is destroyed, the other will still subsist.

5. All the defences should be as nearly direct as possible; for it has been found by experience, that the soldiers are too apt to fire directly before them, without troubling themselves whether they do execution or not.

6. A fortification should be equally strong on all sides; otherwise the enemy will attack it in the weakest part, whereby its strength will become useless.

7. The more acute the angle at the centre is, the stronger will be the place.

8. In great places dry ditches are preferable to those filled with water, because sallies, retreats, succours, &c. are necessary; but, in small fortresses, wet ditches, that can be drained, are the best, as standing in need of no sallies

Field-Fortification is the art of constructing all kinds of temporary works in the field, such as redoubts, field-forts, star-forts, triangular and square forts, heads of bridges, and various sorts of lines, &c. An army entrenched, or fortified in the field, produces, in many respects, the same effect as a fortress; for it covers a country, supplies the want of numbers, stops a superior enemy, or at least obliges him to engage at a disadvantage.

The knowledge of a field-engineer being founded on the principles of fortification, it must be allowed, that the art of fortifying is as necessary to an army in the field as in fortified places; and though the maxims are nearly the same in both, yet the manner of applying and executing them with judgment, is very different.

The materials used in the field are such as can be readily obtained, viz. sand-bags, earth, and fascines ten feet long and one foot thick, which are fastened to the parapet, by means of five pickets driven obliquely into the bank.

When wood cannot be obtained for the fascines, the parapet must be clothed with turf, four inches thick, and a foot and a half square.

The palisades for fortifying the ditch ought to be nine or ten feet long and six inches thick.

The beams belonging to chevaux-de-frize should be twelve feet long, and six inches broad; the spokes seven feet long, four inches thick, and six inches distant from each other.

Gabions must be three or four feet high, and two or three feet in diameter.

FORTIN, Fortlet, or *field-fort*, a sconce or little fort, whose flanked angles are generally distant from one another 120 fathoms.

FORTS, *vitrified*, a very singular kind of structures found in the Highlands and northern parts of Scotland, in which the walls have the appearance of being melted into a solid mass, so as to resemble the lava of a volcano, for which indeed they have been taken by several persons who have visited them.

These walls were taken notice of by Mr. Williams, an engineer, who wrote a treatise on the subject, and was the first who supposed them to be the works of art; other naturalists having attributed them to a volcanic origin. These works are commonly situated on the tops of small hills, commanding an extensive view of the adjacent valley or low country. The area on the summit, varying, as is supposed, according to the number of cattle the proprietor had to protect, or the dependants he was obliged to accommodate, is surrounded with a high and strong wall, of which the stones are melted, most of them entirely; while others, in which the fusion has not been so complete, are sunk in the vitrified matter in such a manner as to be quite inclosed with it; and in some places the fusion has been so perfect, that the ruins appear like masses of coarse glass. Mr. Williams had not only determined the walls in question to be the works of art, but has even hazarded a conjecture as to the manner in which they were constructed, and which, according to him, was as follows. Two parallel dikes of earth or soil being raised, in the direction of the intended wall, with a space between them sufficient for its thickness, the fuel was put in, and set on fire. The stones best adapted for the purpose, called the plum-pudding stone, are every where to be found in the neighbourhood. These

were laid on the fuel, and, when melted, were kept by the frame of earth from running off; and by repeating the operation, the wall was raised to a sufficient height. This opinion of the stones being thrown in without any order, is thought to be confirmed by the circumstance of there not being any where a large one to be seen, nor a stone laid in any particular direction, nor one piece which has not in some degree been affected by the fire. Mr. Williams mentions a fact tending to confirm his hypothesis, viz. of a brick-kiln situated on the declivity of an eminence, so as to be exposed to the wind, which, happening to rise briskly one time when the kiln was burning, so increased the heat, that the bricks were melted, and ran like a lava, for a considerable way down the hill.

This opinion of Mr. Williams has been embraced by several other authors; particularly Mr. Freebairn and Dr. Anderson, the latter having published two treatises upon the buildings in the Archæologia. In the same work, however, we meet with a paper by the hon. Daines Barrington, in which the author expresses quite different sentiments. He observes, that Mr. Williams and the other antiquaries, who suppose the walls in question to be the works of art, imagine that the reason of their being constructed in this manner was the ignorance of cement, which in these remote ages prevailed in Scotland: but with respect to this circumstance he says, that if one side of the wall only was heated, and that to any considerable height, the matter in fusion would in all likelihood drop down to the bottom, without operating as any cement to the loose stones thrown in amongst it. This circumstance of the walls being vitrified only on one side is indeed remarkable, and takes place in most of the forts of this kind to be met with at present; but with regard to it Mr. Barrington observes that he himself has been twice in the Highlands of Scotland, and has found very few hills of any height which were clothed with wood: the trouble therefore of carrying it up to the top of such a mountain would be very considerable.

According to Mr. Cardonnel, the largest of the vitrified forts is situated on the hill of Knockfarril, to the south of the valley of Strathpeffer, two miles west from Dingwall in Ross-shire. The inclosure is 120 feet long and 40 broad within the walls; strengthened on the outside with works at each end. The fort next in consequence to that of Knockfarril is situated on the hill of Craig-Phadric near Inverness.

Besides these fortifications, the hill of Noth affords a remarkable appearance of the same kind: of which Mr. Cordiner gives the following description, not from his own observation, but those of a gentleman of credit who visited the place. "On the top of the hill there is an oblong hollow, as I could guess, of about an English acre, covered with a fine sward of grass: in the middle towards the east end of this hollow is a large and deep well. The hollow is surrounded on all sides with a thick rampart of stones. On three sides of this rampart, from eight to twelve feet thick, is one compact body of stones and minerals which have been in a state of fusion, resembling a mixture of stone and iron-ore, all vitrified, calcined, and incorporated. On the north side, the rampart consists of broken pieces of rock, which have the appearance of having been torn to pieces by some extraordinary violence. If the calcined compact wall exists under them, it is not at present visible."

In the Phil. Trans. of the Royal Society of London for 1777, part II. is an account of Creek Faterick, there termed a volcanic hill near Inverness, in which the writer does not hesitate to pronounce this hill an extinguished volcano: and, having sent specimens of the burnt matter for the inspection of the Royal Society, the secretary subjoins a note to the paper, intimating that these specimens, having been examined by some of the members well acquainted with volcanic productions, were by them judged to be real lava.

Mr. Tytler agrees with those who think the vitrified structures to be artificial works; but he differs from Mr. Williams and others who think that they were vitrified on purpose for cementing the materials together. His reason for this is, that the number of forts that show marks of vitrification is inconsiderable when compared with those that do not. He therefore considers the vitrification as accidental, and describes the manner in which he conceives it must have been accomplished. Among other observations in confirmation of his opinion, he urges, that in the fortification on Craig-Phadric, a large portion of the outward rampart bears no marks of vitrifications. Mr. Cordiner, on the other hand, is of opinion that the vitrifications in question cannot have been the works of art, and ridicules the contrary hypothesis, though without adducing any argument against it.

Mr. Tytler concludes his dissertation with a conjecture, which indeed seems well supported, that the forts in question were constructed, not only before the Roman invasion, but before the introduction of the rites of the Druids into Britain; as "there appears no probability that the inhabitants either lived under such a government as we know to have prevailed under the influence of the Druids, or had any acquaintance with those arts which it is certain they cultivated." On a view of the disputes which have agitated the learned on this obscure subject, we can only observe, that their arguments seem to have placed it in a state of equiponderance, and that the fact remains open to the investigation of future speculators.

FOSS, in fortification, a hollow place, commonly full of water, lying between the scarp and counterscarp, below the rampart; and turning round a fortified place or a post that is to be defended.

FOSSA, in ancient English customs, was used to signify a ditch full of water, wherein women, convicted of felony, were drowned.

Foss-way, one of the four principal highways of England, that anciently led through the kingdom; supposed to be made by the Romans, having a ditch upon one side.

FOSSARII, in antiquity, a sort of officers in the Eastern church, whose business it was to inter the dead.

FOSSIL, in natural history, denotes in general all things dug out of the earth: whether they be natives thereof, as metals, stones, salts, earths, and other minerals; or extraneous, reposited in the bowels of the earth by some extraordinary means, as earthquakes, the deluge, &c. See Metal, Stone, &c.

Native fossils, according to Dr. Hill, are substances

found either buried in the earth, or lying on its surface, of a plain simple structure, and showing no signs of having contained vessels or circulating juices. These are subdivided by the same author, 1. Into fossils naturally and essentially simple. Of these some are neither inflammable, nor soluble in water; as simple earths, talcs, fibrariæ, gypsum, selenitæ, crystals, and spars: others, though uninflammable, are soluble in water; as all the simple salts: and others, on the contrary, are inflammable, but not soluble in water; as sulphur, auripigmentum, zarnich, amber, ambergris, gagates, asphaltum, ampelites, lithanthrax, naphtha, and pissasphalta. 2. The second general subdivision of fossils comprehends all such as are naturally compound, but unmetallic. Of these some are neither inflammable, nor soluble in water; as compound earths, stone, septariæ, siderochita, semipellucid gems, &c.: others are soluble in water, but not inflammable; as all the metallic salts: and, lastly, some are inflammable, but not soluble in water; as the marcasites, pyritæ, and phlogonia. 3. The third and last general division of fossils comprehends all the metallic ores; which are bodies naturally hard, remarkably heavy, and fusible in fire. Of these some are perfectly metallic, as being malleable when pure; such are gold, lead, silver, copper, iron, and tin: others are imperfectly metallic, as not being malleable even in their purest state; such are antimony, bismuth, cobalt, zinc, &c. Of all these substances the reader will find a particular description under their respective heads.

Extraneous fossils are bodies of the vegetable or animal kingdoms accidentally buried in the earth. Of the vegetable kingdom there are principally three kinds, trees or parts of them, herbaceous plants, and corals; and of the animal kingdom there are four kinds, sea-shells, the teeth or bony palates and bones of fishes, complete fishes, and the bones of land-animals. See Bones, Tree, Wood, Plant, Shell, &c. These adventitious, or extraneous fossils, thus found buried in great abundance in divers parts of the earth, have employed the curiosity of several of our latest naturalists, who have each a different system to account for the surprizing appearances of petrified sea-fishes, in places far remote from the sea, and on the tops of mountains; shells in the middle of quarries of stone; and of elephants' teeth, and bones of various animals, peculiar to the southern climates, and plants only growing in the East, found fossil in our northern and western parts.

Some will have these shells, &c. to be real stones, and stone plants, formed after the usual manner of other figured stones; of which opinion is the learned Dr. Lister. Another opinion is, that these fossil shells, with all their foreign bodies found within the earth, as bones, trees, plants, &c. were buried therein at the time of the universal deluge; and that, having been penetrated by the calcareous or siliceous matter abounding chiefly in watery places, and then in a state of solution they have been preserved entire, and sometimes petrified. Others think, that those shells, found at the tops of the highest mountains, could never have been carried thither by the waters, even of the Deluge; inasmuch as most of these aquatic animals, on account of the weight of their shells, always remain at the bottom of the water, and never move but close along the ground. They imagine, that a year's continuance of the waters of the Deluge, intermixed with the salt waters of the sea, upon the surface of the earth, might well give occasion to the production of shells of various kinds in different climates; and that the universal saltness of the water was the real cause of their resemblance to the sea-shells, as the lakes formed daily by the retention of rain or spring water produce different kinds. Others think, that the waters of the sea and the rivers, with those which fell from heaven, turned the whole surface of the earth upside down; after the same manner as the waters of the Loire, and other rivers, which roll in a sandy bottom, overturn all their sands, and even the earth itself, in their swellings and inundations; and that in this general subversion, the shells came to be interred here, fishes there, trees in another place, &c.

Dr. Woodward, in his Natural History of the Earth, pursuing and improving the hypothesis of Dr. Burnet, maintains the whole mass of earth, with every thing belonging to it, to have been so broken and dissolved at the time of the Deluge, that a new earth was then formed on the bosom of the water, consisting of different strata, or beds of terrestrial matter, ranged over each other usually according to the order of their specific gravity. By this means plants, animals, and especially fishes and shells, not yet dissolved among the rest, remained mixed and blended among the mineral and fossil matters; which preserved them, or at least assumed and retained their figures and impressions either indentedly, or in relievo.

FOTHER, or *fodder*, in mining. See Fodder.

FOTHERGILLA, a genus of the polyandria and digynia class and order. The calyx is an ament ovate; scales one-flowered; corolla calyx-form, one-petalled, five-cleft. There is one species, a tree of Caroline resembling the alder.

FOUL, in the sea-language, is used when a ship has been long untrimmed, so that the grass, weeds, or barnacles, grow to her sides under water. A rope is also foul when it is either tangled in itself, or hindered by another, so that it cannot run, or be overhawled.

Foul, imports, also, the running of one ship against another. This happens sometimes by the violence of the wind, and sometimes by the carelessness of the people on board, to ships in the same convoy, and to ships in port by means of others coming in. The damages occasioned by running foul, are of the nature of those in which both parties must bear a part. They are usually made half to fall upon the sufferer, and half upon the vessel which did the injury: but in cases where it is evidently the fault of the master of the vessel, he alone is to bear the damage.

Foul-water. A ship is said to make foul-water, when being under sail, she comes into such shoal-water, that though her keel does not touch the ground, yet it comes so near it, that the motion of water under her raises the mud from the bottom.

FOUNDATION, in architecture, is that part of a building which is under ground. See Architecture.

FOUNDER, in a general sense, the person who lays a foundation, or endows a church, school, religious-house, or other charitable institution. The founder of

a church may preserve to himself the right of patronage or presentation to the living.

Founder, also implies an artist who casts metals, in various forms, for different uses, as guns, bells, statues, printing characters, candlesticks, buckles, &c. whence they are denominated gun-founders, bell-founders, figure-founders, letter-founders, founders of small works, &c. See Foundery.

The most common implements used by the founder are, several different sized pairs of open frames, fig. 1, called flasks; two or three single-handed ladles, fig. 4; a large double-handed ladle, fig. 5; a wooden bar, fig. 6, called a striker; a flat iron rammer, fig. 7; several hand screws, fig. 8; a small trowel with a square end, fig. 9; also, a great quantity of damp loamy sand, and a small quantity of the same, which has been burnt in the furnace, and is kept dry. An exact pattern of the thing to be cast is, in most cases, to be made in wood: the workmen selects a pair of flasks, whose size is best adapted to the size of the article, sets it on a board, H, fills the under one with sand, rams it in with the rammer, fig. 7, and scrapes off the loose sand with the striker, fig. 6; he then with his trowel, fig. 9, digs out a space large enough to contain the pattern for the article (which we will in this case suppose to be a crow for a mill-stone, see Flour-mill, and Figs 2 and 3,) into this space the pattern is placed, and the sand is laid close round it, and pressed and flattened down with the trowel, so as to bury the lower half of it, as shown in the flask GI; a thin layer of dry sand is then sprinkled over it, and the other empty flask, EF, is put upon the under one, its place being determined by the points, *h i k*, in the upper flask EF, which enter the holes, *m n*, in the under flask GI; a round stick is then held upright upon the pattern, and the sand filled and rammed round it; the stick is then withdrawn, which leaves a hole, *d*, through the sand, through which the metal is to be poured. The upper flask, with the sand in it, is then lifted off, and laid upon its side, as shown in fig. 1, the dry sand making the separation at the proper place, so as to leave an impression, *o p q r*, in the upper flask, of the same size and shape as the upper half of the pattern: the sand around the pattern, *s t v w*, in the flask GI is then slightly damped, with a sponge, to make it adhere better together, and the pattern is lifted out, by screwing one or more of the screws, fig. 8, into it, leaving an impression of the lower half of the pattern, so that when the two flasks are put together again, the cavity of the whole article is formed, into which the metal is poured, through the hole *d*. For small work, the metal is melted in a furnace, blown by bellows; it has a small hole near its bottom, which is stopped with clay: when the metal is melted, this clay is poked out, and the metal which runs out, is caught in the ladle, fig. 5; when this is nearly full, it is taken up by two men (one of whom walks first, between the handles, *a b*, and another at the end, *d*,) and is distributed to the different flasks: for still smaller work, this is done by one man, who uses the ladle, fig. 4. For large works, the metal is melted in an air or draft furnace; and is conveyed to the moulds, which are in that case sunk in the ground, by little channels made in the sand, of which the floor of the foundery is composed. When the article that has been cast, is first taken out of the sand, it has a knob or runner sticking to it, in the hole, *d*, fig. 1, and has usually thin pieces sticking out from the sides of it, where the two flasks did not exactly fit: these are all taken off with a chisel, the sand is shook off the surface by knocking, and the founder's business is done.

For some articles which have one side a plain surface, as square bars, &c. no flasks are used, but the pattern is laid in a space large enough to bury it, which is made in the sand on the ground, and, the sand is banked up round it; it is then taken out as above, and the metal is poured into the cavity formed by it, till the same is full enough. The mould for large articles, as bells, boilers, cylinders, pipes, &c. are made of wet tempered loam, and dried.

Founder, in the sea-language, a ship is said to founder, when by an extraordinary leak, or by a great sea breaking in upon her, she is so filled with water, that she cannot be freed of it; so that she can neither veer nor steer, but lies like a log; and not being able to swim along, will at last sink.

FOUNDERY or *foundry*, the art of casting all sorts of metals into different forms. It likewise signifies the work-house, or smelting-hut, in which these operations are performed.

Foundery *in small works, or cutting in sand.* The sand used for casting small works is, at first, of a pretty soft, yellowish, and clammy nature; but it being necessary to strew charcoal dust in the mould, it at length becomes of a quite black colour. This sand is worked over and over, on a board, with a roller, and a sort of knife; being placed over a trough to receive it, after it is by these means sufficiently prepared.

This done, they take a wooden board of a length and breadth proportioned to the things to be cast, and putting a ledge round it, they fill it with sand, a little moistened, to make it duly cohere. Then they take out either wood or metal models of what they intend to cast, and apply them so to the mould and press them into the sand, as to leave their impression there. Along the middle of the mould is laid half a small brass-cylinder, as the chief canal for the metal to run through, when melted into the models, or patterns; and from this chief canal are placed several others, which extend to each model or pattern placed in the frame. After this frame is finished they take out the patterns, by first loosening them all round, that the sand may not give way.

Then they proceed to work the other half of the mould with the same patterns in just such another frame, only that it has pins, which, entering into holes that correspond to it in the other, make the two cavities of the pattern fall exactly on each other.

The frame thus moulded, is carried to the melter, who, after extending the chief canal of the counterpart, and adding the cross canals to the several models in both, and strewing mill-dust over them, dries them in a kind of oven for that purpose.

Both parts of the mould being dry, they are joined together by means of the pins; and to prevent their giving way, on account of the melted metal passing through the chief cylindrical canal, they are screwed or wedged up like a kind of press.

While the moulds are thus preparing, the metal is fus-

ing in a crucible of a size proportioned to the quantity of metal intended to be cast.

FOUNDERY *of statues.* See BRONZE and STATUE.

FOUNDERY OF BELLS. The metal, it is to be observed, is different for bells, from what it is for statues; there being no tin in the statue-metal: but there is a fifth, and sometimes more, in the bell metal.

The dimensions of the core, and the wax, for bells, (if a ring of bells especially) are not left to chance, but must be measured on a scale, which gives the height, aperture, and thickness necessary for the several tones required.

It is on the wax that the several mouldings and other ornaments are formed to be represented in relievo, on the outside of the bell.

The business of bell-foundry is reducible to three particulars. 1. The proportion of a bell. 2. The forming of the mould; and, 3. The melting of the metal.

The proportions of our bells differ much from those of the Chinese; in ours the modern proportions are to make the diameter fifteen times the thickness of the brim, and twelve times in height.

There are two kinds of proportions, viz. the simple and the relative; the former are those proportions only that are between the several parts of a bell. to render it sonorous; the relative proportions establish a requisite harmony between several bells.

The particulars necessary for making the mould of a bell, are, 1. The earth: the most cohesive is the best: it must be well ground and sifted, to prevent any chinks. 2. Brick-stone; which must be used for the mine, mould, or core, and for the furnace. 3. Horse-dung, hair, and hemp, mixed with the earth, to render the cement more binding. 4. The wax for inscriptions, coats of arms, &c. 5. The tallow equally mixed with the wax, in order to put a slight lay of it upon the outer mould, before any letters are applied to it. 6. The coals to dry the mould.

For making the mould, they have a scaffold consisting of four boards, ranged upon tressels. Upon this, they carry the earth, grossly diluted, to mix it with horse-dung, beating the whole with a large spatula.

The compasses of construction is the chief instrument for making the mould, which consists of two different legs joined by a third piece. And last of all, the founders shelves on which are the engravings of the letters, cartridges, coats of arms, &c.

They first dig a hole, of a sufficient depth to contain the mould of the bell, together with the case or cannon, under-ground; and about six inches lower than the terreplain, where the work is performed. The whole must be wide enough for a free passage between the mould and walls of the hole; or between one mould and another, when several bells are to be cast. At the centre of the hole is a stake erected, that is strongly fastened in the ground. This supports an iron peg, on which the pivot of the second branch of the compasses turns. The stake is encompassed with a solid brick work, perfectly round, about half a foot high, and of the proposed bell's diameter. This they call a mill-stone. The parts of the mould are the core, the model of the bell, and the shell. When the outer surface of the core is formed, they begin to raise the core, which is made of bricks that are laid in courses of equal height upon a lay of plain earth. At the laying of each brick they bring near it the branch of the compasses, on which the curve of the core is shaped, so that there may remain between it and the curve the distance of a line, to be afterwards filled up with layers of cement. The work is continued to the top, only leaving an opening for the coals to bake the core. This work is covered with a layer of cement, made of earth and horse-dung, on which they move the compasses of construction, to make it of an even smoothness every where.

The first layer being finished, they put the fire to the core, by filling it half with coals, through an opening that is kept shut, during the baking, with a cake of earth, that has been separately baked. The first fire consumes the stake, and the fire is left in the core half, and sometimes a whole day; the first layer being thoroughly dry, they cover it with a second, third, and fourth; each being smoothed by the board of the compasses, and thoroughly dried before they proceed to another.

The core being completed, they take the compasses to pieces, with intent to cut off the thickness of the model, and the compasses are immediately put in their place, to begin a second piece of the mould. It consists of a mixture of earth and hair, applied with the hand on the core, in several cakes that close together. This work is finished by several layers of a thinner cement of the same matter, smoothed by the compasses, and thoroughly dried before another is laid on. The first layer of the model is a mixture of wax and grease spread over the whole. After which are applied the inscriptions, coats of arms, &c. besmeared with a pencil dipt in a vessel of wax in a chaffing-dish: this is done for every letter. Before the shell is begun, the compasses are taken to pieces, to cut off all the wood that fills the place of the thickness to be given to the shell.

The first layer is the same earth with the rest, sifted very fine; whilst it is tempering in water, it is mixed with cow's hair, to make it cohere. The whole being a thin cullis, is gently poured on the model, that fills exactly all the sinuosities of the figures, &c. and this is repeated till the whole is two lines thick over the model. When this layer is thoroughly dried, they cover it with a second of the same matter, but something thicker: when this second layer becomes of some consistence, they apply the compasses again, and light a fire in the core, so as to melt off the wax of the inscriptions, &c.

After this, they go on with other layers of the shell, by means of the compasses. Here they add to the cow's hair a quantity of hemp, spread upon the layers, and afterwards smoothed by the board of the compasses. The thickness of the shell comes to four or five inches lower than the mill-stone before observed, and surrounds it quite close, which prevents the extravasation of the metal. The wax should be taken out before the melting of the metal.

The ear of the bell requires a separate work, which is done during the drying of the several incrustations of the cement. It has seven rings, the seventh is called the bridge, and unites the others, being a perpendicular support to strengthen the curves. It has an aperture at the top, to admit a large iron-peg bent at the bottom; and

this is introduced into two holes in the beam, fastened with two strong iron-keys. There are models made of the rings, with masses of beaten earth, that are dried in the fire, in order to have the hollow of them. These rings are gently pressed upon a layer of earth and cow's hair, one half of its depth; and then taken out, without breaking the mould. This operation is repeated twelve times for twelve half-moulds, that two and two united make the hollows of the six rings: the same they do for the hollow of the bridge, and bake them all, to unite them together.

Upon the open place left for the coals to be put in, are placed the rings that constitute the ear. They first put into this open place the iron-ring to support the clapper of the bell; then they make a round cake of clay, to fill up the diameter of the thickness of the core. This case after baking, is clapped upon the opening, and soldered with a thin mortar spread over it, which binds the cover close to the core.

The hollow of the model is filled with an earth, sufficiently moist, to fix on the place which is strewed, at several times, upon the cover of the core; and they beat it gently with a pestle, to a proper height; and a workman smooths the earth at top with a wooden trowel dipped in water.

Upon this cover, to be taken off afterwards, they assemble the hollows of the rings. When every thing is in its proper place, they strengthen the outside of the hollows with mortar, in order to bind them with the bridge, and keep them steady at the bottom, by means of a cake of the same mortar which fills up the whole aperture of the shell. This they let dry, that it may be removed without breaking. To make room for the metal they pull off the hollows of the rings, through which the metal is to pass, before it enters into the vacuity of the mould. The shell being unloaded of its ear, they range under the mill-stone five or six pieces of wood, about two feet long, and thick enough to reach almost the lower part of the shell; between these and the mould they drive in wooden wedges with a mallet, to shake the shell of the model whereon it rests, so as to be pulled up and got out of the pit.

When this and the wax are removed, they break the model and layer of earth, through which the metal must run, from the hollow of the rings, between the shell and the core. They smoke the inside of the shell, by burning straw under it that helps to smooth the surface of the bell. Then they put the shell in the place, so as to leave the same interval between that and the core; and before the hollows of the rings or the cap are put on again, they add two vents, that are united to the rings, and to each other, by a mass of baked cement. After which they put on this mass of the cap, the rings, and the vent, over the shell, and solder it with thin cement, which is dried gradually by covering it with burning coals. Then they fill up the pit with earth, beating it strongly all the time round the mould.

The furnace has a place for the fire, and another for the metal. The fire-place has a large chimney with a spacious ash-hole. The furnace which contains the metal, is vaulted, the bottom is made of earth, rammed down; the rest is built with brick. It has four apertures; the first, through which the flame reverberates; the second is closed with a stoppel that is opened for the metal to run; the others are to separate the dross or scoriæ, of the metal by wooden rakes: through these last apertures passes the thick smoke. The ground of the furnace is built sloping, for the metal to run down.

Foundery *of great guns and mortar pieces.* The method of casting these pieces is little different from that of bells: they are run massy, without any core, being determined by the hollow of the shell; and they are afterwards bored with a steel trapan, which is worked either by horses, or a water-mill.

For the metal parts, proportions, &c. of these pieces. See Cannon.

Foundry, *letter*, or casting of printing letters. See Type.

FOUNT, or *font*, among printers, a set or quantity of letters, and all the appendages belonging thereto, as numeral characters, quadrates, points, &c. cast by a letter-founder, and sorted. Founts are large or small, according to the demand of the printer, who orders them by the hundred weight, or by sheets. When a printer orders a fount of five hundred, he means that the fount, consisting of letters, points, spaces, quadrates, &c. shall weigh 500lb. When he demands a fount of ten sheets, it is understood, that with that fount he shall be able to compose ten sheets, or twenty forms, without being obliged to distribute, that is, take them to pieces. The founder proceeds accordingly; he reckons 120lb. for a sheet, including the quadrates, &c. or 60lb. for a form, which is only half a sheet: not that the sheet always weighs 120lb. or the form 60lb. on the contrary it varies according to the size of the form: besides, it is always supposed that there are letters left in the cases. As therefore every sheet does not comprehend the same number of letters, nor the same sort of letters, we must observe, that, as in every language some sounds recur more frequently than others, some letters will be in much more use, and oftener repeated than others, and consequently their cells or cases should be better stored than those of the letters which do not recur so frequently: thus, a fount does not contain an equal number of *a* and *b*, or of *b* and *c*, &c. the letter-founders have therefore a list or tariff, or, as the French call it, a police, by which they regulate the proportions between the different sorts of characters that compose a fount; and it is evident that this tariff will vary in different languages, but will remain the same for all sorts of characters employed in the same language. See Printing.

FOUNTAIN, or *artificial fountain* in hydraulics, called also a jet d'eau, is a contrivance by which water is violently spouted upwards. See Hydraulics.

FOURCHE'E, or fourchy, in heraldry, an appellation given to a cross forked at the ends.

Fourche'e, or *fourching*, in law, signifies the delaying or putting off an action, which might have been brought to determination in a shorter time.

FOURTEENTH, in music, the octave, or replicate, of the seventh. A distance comprehending thirteen diatonic intervals.

FOURTH, in music, a distance comprising three diatonic intervals: *i. e.* two tones and a half. The fourth is the third of the consonances in the order of their generation.

Lesser Fourth, an interval consisting of five semitones.

Greater or sharp Fourth, an interval consisting of six semitones.

FOX. See Canis.

Fox-glove See Digitalis.

FRACTION. See Algebra and Arithmetic.

FRACTURE, in surgery, a rupture of a bone, or a solution of a continuity in a bone, when it is crushed or broken by some external cause. See Surgery.

FRAGARIA, the strawberry; a genus of the polygynia order, in the icosandria class of plants; and in the natural method ranking under the 35th order, senticosæ. The calyx is decemfid; the petals five; the receptacle of the seeds ovate, in the form of a berry and deciduous. There are three species, but only one is deserving of particular notice, viz. I. the vesca, or cultivated strawberry. The principal varieties are, 1. The sylvestris, or wood strawberry, with oval sawed leaves, and small round fruit. 2. The Virginian scarlet, or Virginia strawberry with oblong oval sawed leaves, and a roundish scarlet coloured fruit. 3. The moschatta, or hautboy, or musky strawberry, having oval, lanceolate rough leaves, and large pale red fruit. 4. The chiloensis, or Chili strawberry, of which the carolina is a variety with large, oval, thick, downy leaves, large flowers, and very large firm fruit. 5. The alpina, alpine, or monthly strawberry, having small oval leaves, small flowers, and moderate-sized, oblong, pointed fruit. All these varieties are hardy, low, perennials, durable in root; but the leaves and fruit-stalks are renewed annually in spring. They flower in May and June, and their fruit comes to perfection in June, July, and August; the alpine kind continuing till the beginning of winter. They all thrive in any common garden soil, producing abundant crops annually without much trouble. They increase exceedingly every summer, both by off-sets or suckers from the sides of the plants, and by the runners or strings, all of these rooting and forming plants at every joint, each of which separately planted bears a few fruit the following year, and bear in great perfection the succeeding summer. Those of the alpine kind will even bear fruit the same year that they are formed. All the sorts are commonly cultivated in kitchen-gardens, in beds or borders of common earth, in rows lengthwise 15 or 18 inches distance; the plants the same distance from one another in each row. Patches of the different sorts, disposed here and there in the fronts of the different compartments of the pleasure-ground, will appear ornamental both in their flowers and fruit, and make an agreeable variety. Strawberries, eaten either alone, or with sugar and cream, are universally esteemed a most delicious fruit. They are grateful, cooling, subacid, and juicy. Though taken in large quantities, they seldom disagree. They promote perspiration, impart a violet smell to the urine, and dissolve the tartareous incrustations on the teeth. People afflicted with the gout or stone have found relief by using them very largely; and Hoffman says, he has known consumptive people cured by them. The bark of the root is astringent. Sheap and goats eat the plant; cows are not found of it; horses and swine refuse it.

II. The monophylla, or simple leaved strawberry, produces also esculent fruit, and differs from the former species only in the leaf.

III. The sterilis, or barren strawberry, is destitute of fruit, though it perfects seed.

FRÆNUM, in anatomy, a term applied to some membranous ligaments of the body.

Frænum linguæ, the ligament under the tongue, which sometimes ties it down too close to the bottom of the mouth; and then requires to be incised or divided, in order to give this organ its proper and free motion.

FRAISE, in fortification, a kind of defence consisting of pointed stakes, six or seven feet long, driven parallel to the horizon into the retrenchments of a camp, a half-moon, &c. and to prevent any approach or scalade. See Fortification.

FRANCHISE, in a general sense, a privilege or exemption from ordinary jurisdiction; as that for a corporation to hold pleas among themselves to such a value, or the like.

Franchises and liberties being usually held by charter, are all said to be derived from the crown, but some lie in prescription without the help of any charter.

Farnchise royal, seems to be that where the king's writ does not run; but Bracton says, that a franchise royal is where the king grants to one and his heirs an exemption of toll, &c.

Franchise of quarters, a certain place or district at Rome, wherein are the houses of the ambassadors of the princes of Europe; and where such as retire cannot be arrested or seized by the shirri or serjeants, nor prosecuted at law. Several of the popes published their bulls and ordinances against the abuse made of this privilege, which rescued so considerable a part of the city, by the enlargement of these places, from their authority, and rendered them a retreat for the most abandoned persons. At last Innocent XI. expressly refused to receive any more ambassadors, but such as would make a formal renunciation of the franchise of quarters.

FRANCISCAN MONKS, Friars' Minor, or Grey Friars, religious of the order of St. Francis, founded by him in the year 1209.

The rule of the Franciscans, as established by St. Francis himself, is briefly this: they are to live in common, to observe chastity, and to pay obedience to the pope and their superiors. Before they can be admitted into the order they are obliged to sell all they have, and give it to the poor: they are to perform a year's noviciate, and when admitted, never to quit the order on any account. They are to fast from the feast of All Saints to the Nativity. This order has produced four popes, forty-two cardinals, and an infinite number of patriarchs. The Franciscans had sixty-three monasteries in England, one of which was in the parish of St. Nicholas in London. It is said this order possessed (before the French revolution) 40,000 monasteries, hermitages, or chapels, in the different quarters of the globe.

FRANK ALMOIGN, signifies a tenure by spiritual service, where lands or tenements were held by an ecclesiastical corporation, sole or aggregate, to them and their successors, of some lord and his heirs, in free and perpetual alms.

Frank fee, signifies the same thing as holding lands and tenements in fee simple; that is, to any person and his heirs, and not by such services as is required by ancient demesne, but is pleaded at common law.

Frank ferm, anciently signified lands charged in the nature of the fee by feoffment, &c. out of the knight's service for other certain yearly services.

Frank fold, is where the lord has the liberty of folding his tenants' sheep within his manor.

Frank incense, in chemistry. It is well known that a resinous juice exudes from the pinus sylvestris, or common Scotch fir, which hardens into tears. The same, or a similar exudation, appears in the spruce fir. These tears constitute the substance called *thus*, or common frankincense. See Resin and Pinus.

Franklanguage, or *lingua franca*, a kind of jargon spoken on the Mediterranean, and particularly throughout the coasts and parts of the Levant, composed of Italian, Spanish, French, vulgar Greek, and other languages.

Frank law, a word applied to the free and common law of the land, or the benefit a person has by it.

Frank marriage, is where a person, seized in fee of lands or tenements, has given them to another with his daughter, sister, or some women otherwise of kin to him, in free marriage, by virtue of which the husband and wife have an estate in special tail, and shall hold the land of the donor, discharged of all services, except fealty, to the fifth degree.

Frank pledge, in English law, signifies a pledge or surety for the behaviour of freemen. According to the ancient custom of England, for the preservation of the public peace, every free-born man, at the age of 14, except religious persons, clerks, knights, and their eldest sons, was obliged to give security for his truth and behaviour towards the king and his subjects, or else be imprisoned. Accordingly, a certain number of neighbours became interchangeably bound for each other, to see each person of their pledge forthcoming at all times, or to answer for the offence of any one gone away; so that whenever any person offended, it was presently inquired in what pledge he was; and there the persons bound either produced the offender in 31 days, or made satisfaction for his offence.

Frank, or Franc, an ancient coin, either of gold or silver, struck and current in France. The value of the gold frank was somewhat more than that of the gold crown; the silver frank was a third of the gold one: this coin is long out of use, though the term is still retained as the name of a money of account; in which sense it is equivalent to the livre, or 20 sols.

FRANKENIA, *sea-heath*, or *sea-chick-weed*, a genus of the hexandria monogynia class of plants, the flower of which consists of five petals, with a plain limb: the fruit is an oval, unilocular capsule, covered by the cup, and containing a great many ovated very small seeds. There are three species of this weed.

FRATERNITY, in the Roman catholic countries, signifies a society for the improvement of devotion.

Fraternity, in a civil sense, a company or guild of certain artificers or traders.

FRATRICELLI, *little brothers*, in church history, a sect of heretics who appeared in Italy about the year 1298, and afterwards spread all over Europe. They wore the habit of the Franciscan order, and pretended that ecclesiastics ought to have no possessions of their own.

FRATRIAGE, the partition among brothers or coheirs, coming to the same inheritance or succession. It more particularly signifies a younger brother's inheritance; or whatever the younger sons possess of the father's estate, which, in our ancient law, they are said to enjoy ratione fratriagii; and were to do homage for the same to the elder brother, he being bound to do homage to the superior lord for the whole.

FRAUD, in law. All deceitful practices in defrauding or endeavouring to defraud another of his own right, by means of some artful device, contrary to the plain rules of common honesty, are condemned by the common law, and punishable according to the heinousness of the offence. Co. Lit, b. 3.

The distinction laid down as proper to be attended to in all cases of this kind, is this, that in such impositions or deceits, where common prudence might guard persons from the offence, it is not indictable, but the party is left to his civil remedy; but where false weights or measures are used, or false tokens produced, or such measures taken to defraud or deceive, as people cannot by any ordinary care or prudence be guarded against, there it is an offence indictable. Burr. 1120.

Persons convicted of obtaining money or goods by false pretences, or sending threatening letters to extort money or goods, may be punished by fine and imprisonment, or by pillory, whipping, or transportation. 30 G. II. c. 24.

A fraudulent conveyance of lands or goods to deceive creditors, as to creditors is void in law. And a fraudulent conveyance in order to defraud purchasers, is also to such purchasess void; and the persons justifying or putting off such grants as good, shall forfeit a year's value of the lands, and the full value of the goods and chattels, and likewise shall be imprisoned. When, however, conveyances are fraudently made, they are not void to all persons, but only to those that afterwards come to the land as purchasers on good consideration. A general gift made of all the goods of a person may be reasonably suspected to be by fraud, even though a true debt is owing to the party to whom made; and it is void against other creditors of the donor. Here the several marks of fraud in a gift or grant of goods, are as follow, viz. 1. If it is general, without any exception of some things of necessity. 2. If the donor continues to possess and use the goods. 3. If the deed is made in secret. 3. If there is a trust between the parties; or, 5. If made whilst the action is depending. Where a person is party to a fraud, all that follows thereupon will be intended to be done by him, though fraud shall not be presumed or adjudged to be so, until found by jury.

By the statute of frauds, 29 Car. II. agreements for the sale of lands, leases, &c. are required to be in writing. See 3 and 4 Will. and Mary, c. 14.

FRAXINUS, the *ash*, a genus of the diœcia order, in the polygamia class of plants, and in the natural method ranking under the 44th order, sepiariæ. There is no hermaphrodite calyx, or it is quadripartite; and there is either no corolla, or it is tetrapetalous; there are two stamina, one pistil, one lanceolated seed, and the pistil of the female is lanceolated. There are four species, of which the most useful is the common ash, which is so well known that it needs no description. If a wood of these trees is rightly managed, it will turn

greatly to the advantage of the owner: for by the underwood, which will be fit to cut every eight or ten years, there will be a continual income, more than sufficient to pay the rent of the ground and all other charges; and still there will be a stock preserved for timber, which in 23 years will be worth 114*l.* per acre. This tree flourishes best in groves, but grows very well in rich soil in open fields. It bears transplanting and lopping. In the north of Lancashire they lop the tops of these trees to feed the cattle in autumn when the grass is on the decline, the cattle peeling off the bark as food. The wood has the singular property of being nearly as good when young as when old. It is hard and tough, and is much used to make the tools employed in husbandry. The ashes of the wood afford very good potash. The bark is used in tanning calf-skin. A slight infusion of it appears of a pale yellowish colour, when viewed betwixt the eye and the light; but when looked down upon, or placed betwixt the eye and an opaque object, appears blue. This blueness is destroyed by the addition of an acid, but recovered by alkalies. The seeds are acrid and bitter. In the church-yard of Lochabar in Scotland, Dr. Walker measured the trunk of a dead ash-tree, which, at five feet from the surface of the ground, was 58 feet in circumference.

FREE, among seamen. The pump is said to free the ship, when it throws out the water faster than it leaks into her. To free the boat, is bailing or lading out the water therein.

Free-bench, signifies that estate in copyhold which the wife, being espoused a virgin, has after the decease of her husband for her dower, according to the custom of the manor. In regard to this free-bench, different manors have different customs, and in the manor of east and west Enbourne in the county of Berks, and in other parts of England, there is a custom, that when a copyhold tenant dies, the widow shall have her free-bench in all the deceased husband's lands, dum sola et casta fuerit, while she lives single and chaste; but if she is found to be guilty of incontinency, she shall forfeit her estate. Nevertheless, upon her coming into the court of the manor riding backwards on a black ram, with his tail in her hand, rehearsing a certain form of words, the steward is bound by custom to restore her to her free-bench.

FREEDOM of a corporation, the right of enjoying all the privileges and immunities belonging to it.

The freedom of cities, and other corporations, is regularly obtained by serving an apprenticeship of seven years; but it is also sometimes purchased with money, and sometimes conferred by way of compliment.

FREEHOLD, may be in deed or in law. A freehold in deed is actual seisin of lands or tenements in fee-simple, fee-tail, or for life. A freehold in law is a right to such lands or tenements before entry or seizure.

So there is a seisin in deed, and a seisin in law. A seisin in deed is when a corporal possession is taken; and a seisin in law is where lands descend before entry, or where something is done which amounts in law to an actual seisin. 1 Inst. 31.

Tenant in fee-simple, or fee-tail for life, is said to have a freehold, so called because it distinguishes it from terms of years, chattels upon uncertain interests, lands in villenage, or customary or copyhold lands. 1 Inst. 43.

A freehold cannot be conveyed to pass in future; for then there would be want of a tenant against whom to bring a præcipe; and therefore, notwithstanding such conveyance, the freehold continues in the vendor: but if livery of seisin is afterwards given, the freehold thence passes to the vendee. 2 Wils. 165.

A man is said to be seised of freehold, but to be possessed of other estates, as of copyhold lands, leases for years, or goods and chattels. See Estate and Fee simple.

FREEHOLDERS, such as hold any freehold estate.

FREESTONE, a whitish stone dug up in many parts of England, that works like alabaster, but is more hard and durable, being of excellent use in building, &c. It is a variety of the gritstone, but finer sanded, and a smoother stone, and is called free, from its being of such a constitution as to cut freely in any direction: such is the Portland-stone, and the freestone of Kent.

FREEZE, or Frieze, in commerce, a coarse kind of woollen stuff, or cloth, for winter wear; so called as being freezed or naped on one side.

Freezing, in philosophy, the same with congelation, or the fixing a fluid body into a firm or solid mass by the action of cold. See Cold.

In general cold contracts most bodies, and heat expands them: though there are some instances to the contrary, especially in the extreme cases or states of these qualities of bodies. Thus, though iron, in common with other bodies, expands with heat, yet, when melted, it is always found to expand in cooling again. So also, though water always is found to expand gradually as it is heated, and to contract as it cools, yet in the act of freezing it suddenly expands again, and that with a most enormous force, capable of rending rocks, or bursting very thick shells of metal, &c. A computation of the force of freezing water has been made by the Florentine academicians, from the bursting of a very strong brass globe or shell, by freezing water in it; when, from the known thickness and tenacity of the metal, it was found that the expansive power of a spherule of water only one inch in diameter was sufficient to overcome a resistance of more than 27,000lbs. or 13 tons and a half. See the experiments on bursting thick bomb-shells, by freezing water in them, by major Edward Williams, of the royal artillery, in the Edin. Philos. Trans. vol. ii.

Such a prodigious power of expansion, almost double that of the most powerful steam engines, and exerted in so small a mass, seemingly by the force of cold, was thought a very material argument in favour of those who supposed that cold, like heat, is a positive substance. Dr. Black's discovery of latent heat, however, has now afforded a very easy and natural explication of this phenomenon. He has shown that, in the act of congelation, water is not cooled more than it was before, but rather grows warmer: that as much heat is discharged, and passes from a latent to a sensible state, as, had it been applied to water in its fluid state, would have heated it to 135°. In this process the expansion is occasioned by a great number of minute bubbles suddenly produced. Formerly these were supposed to be cold in the abstract; and to be so subtile that, insinuating themselves into the substance of the fluid, they augmented its bulk, at the same time that, by impeding the motion of its particles upon each other, they changed it from a fluid to a solid. But Dr. Black shows, that these are only air extricated during the

congelation; and to the extrication of this air he ascribes the prodigious expansive force exerted by freezing water. The only question, therefore, now remaining is, by what means this air is extricated, and to take up more room than it naturally does in the fluid? To this it may be answered, that perhaps part of the heat, which is discharged from the freezing water, combines with the air in its unelastic state, and, by restoring its elasticity, gives it that extraordinary force, as is seen also in the case of air suddenly extricated in the explosion of gunpowder.

Cold also usually tends to make bodies electric, which are not so naturally, and to increase the electric properties of such as are so. And it is farther found, that all substances do not transmit cold equally well; but that the best conductors of electricity, viz. metals, are likewise the best conductors of cold. It may farther be added, that when the cold has been carried to such an extremity as to render any body an electric, it then ceases to conduct the cold so well as before. This is exemplified in the practice of the Laplanders and Siberians; where, to exclude the extreme cold of the winters from their habitations the more effectually, and yet to admit a little light, they cut pieces of ice, which in the winter time must always be electric in those countries, and put them into their windows; which they find to be much more effectual in keeping out the cold than any other substance.

Cold, or rather the absence of heat, is the destroyer of all vegetable life, when increased to an excessive degree. It is found that many garden plants and flowers, which seem to be very stout and hardy, go off at a little increase of cold beyond the ordinary standard. And, in severe winters, nature has provided the best natural defence for the cornfields and gardens, namely, a covering of snow, which preserves such parts green and healthy as are under it, while such as are uncovered by it are either killed or greatly injured.

Although the thermometer in England hardly ever descends so low as 0, yet, in the winter of 1780, Mr. Wilson, of Glasgow, observed, that a thermometer laid on the snow sunk to 25° below 0; and Mr. Derham, in the year 1708, observed in England that the mercury stood within one-tenth of an inch of its station when plunged into a mixture of snow and salt. At Petersburgh, in 1732, the thermometer stood at 28° below 0; and when the French academicians wintered near the polar circle, the thermometer sunk to 33° below 0; and in the Asiatic and American continents still greater degrees of cold are often observed.

The effects of these extreme degrees of cold are very surprising. Trees are burst, rocks rent, and rivers and lakes frozen several feet deep: metallic substances blister the skin like red-hot iron: the air, when drawn in by breathing, hurts the lungs, and excites a cough: even the effects of fire, in a great measure, seem to cease; and it is observed, that though metals are kept for a considerable time before a strong fire, they will still freeze water when thrown upon them. When the French mathematicians wintered at Tornea, in Lapland, the external air, when suddenly admitted into their rooms, converted the moisture of the atmosphere into whirls of snow; their breasts seemed to be rent when they breathed it, the contact of it was intolerable to their bodies; and the spirit of wine, which had not been highly rectified, burst some of their thermometers by the congelation of the aqueous part.

Extreme cold too often proves fatal to animals in those countries where the winters are very severe: thus 7000 Swedes perished at once in attempting to pass the mountains which divide Norway from Sweden. But it is not necessary that the cold, in order to prove fatal to human life, should be so very intense as has just been mentioned; it is only requisite to be a little below 32° of Fahrenheit, or the freezing point, accompanied with snow or hail, from which shelter cannot be obtained. The snow which falls upon the cloths, or the uncovered parts of the body, then melts, and by a continual evaporation carries off the animal heat to such a degree, that a sufficient quantity is not left for the support of life. In such cases, the person first feels himself extremely chill and uneasy; he turns listless, unwilling to walk or use exercise to keep himself warm, and at last turns drowsy, sits down to refresh himself with sleep, but wakes no more.

With regard to the term congelation, it is applied to water when it freezes into ice; to metals, when they resume their solid form after being melted by heat; or to glass, wax, pitch, tallow, &c. when they harden again after having been rendered fluid by heat. But it differs from crystallization, which is rather a separation of the particles of a solid from a fluid in which it had been dissolved more by the moisture than the action of heat.

The process of congelation is always attended with the emission of heat, as is found by experiments on the freezing of water, wax, spermacceti, &c.; for in such cases it is always found that a thermometer dipt into the fluid mass keeps continually descending as this cools, till it arrives at a certain point; being the point of freezing, which is peculiar to each fluid, where it is rather stationary, and then rises for a little, while the congelation goes on.

Freezing-point, denotes the point or degree of cold, shown by a mercurial thermometer, at which certain fluids begin to freeze, or, when frozen, at which they begin to thaw again. On Fahrenheit's thermometer this point is at + 32 for water, and at — 40 for quicksilver, these fluids freezing at those two points respectively. It would also be well if the freezing points for other fluids were ascertained, and the whole arranged in a table. See Thermometer.

Freezing-rain, or *raining ice*, a very uncommon kind of shower, which fell in the west of England, in December 1762, of which we have various accounts in the Philosophical Transactions. This rain, as soon as it touched any thing above ground, as a bough, &c. immediately settled into ice; and, by multiplying and enlarging of the icicles, broke all down with its weight. The rain that fell on the snow immediately froze into ice, without sinking in the snow at all. It made an incredible destruction of trees, beyond any thing in all history. "Had it concluded with some gust of wind (says a gentleman on the spot), it might have been of terrible consequence. I weighed the sprig of an ash-tree, of just three-quarters of a pound, the ice on which weighed 16 pounds. Some were frightened with the noise in

the air, till they discerned it was the clatter of icy boughs, dashed against each other." This phenomenon, however, is not uncommon in a less degree, and depends wholly on the nice balance of temperatures in the rain and atmosphere. Dr. Beale observes, that there was no considerable frost observed on the ground during the whole; whence he concludes, that a frost may be very intense and dangerous on the tops of some hills and plains; while in other places it keeps at two, three, or four feet distance above the ground, rivers, lakes, &c. and may wander about very furious in some places, and remiss in others not far off. The frost was followed by glowing heats, and a wonderful forwardness of flowers and fruits.

Freezing mixture. See Cold.

FREIGHT, or Fraight, in navigation and commerce, is the consideration of money agreed to be paid for the use of hire of a ship, or, in a larger sense, the burthen of such ship.

The freight is most frequently determined for the voyage, without respect to time: sometimes it depends on time; in the former case it is either fixed at a certain sum for the whole cargo, or so much per ton, barrel bulk, or other weight or measure, or so much per cent. on the value of the cargo.

If a certain sum is agreed on for the freight of the ship, it must all be paid, although the ship when measured should prove less, unless the burthen is warranted. If the ship is freighted for transporting cattle or slaves at so much per head, and some of them die on the passage, freight is only due for such as are delivered alive; if for lading them, it is due for all put on board.

When a whole ship is freighted, if the master suffers any goods besides those of the freight to be put on board, he is liable for damages.

If the voyage is completed according to the agreement, without any accident, the master has a right to demand the freight before the delivery of the goods; but if such delivery is prevented by negligence or accidents, the parties will be reciprocally responsible in the following manner.

If the merchant should not load the ship within the time agreed on, the master may engage with another, and recover damages.

If the merchant recals the ship after she is laden and sailed, he must pay the whole freight; but if he unloads before the ship has actually sailed, he will in such case only be responsible for damages.

If the merchant loads goods which are not lawful to export, and the ship is prevented from proceeding on that account, he must nevertheless pay the freight.

If the master is not ready to proceed on the voyage at the time stipulated, the merchant may load the whole or part of the cargo on board another ship, and recover damages; but any real casualties will release the master from all damages.

If an embargo is laid on the ship before she sails, the charterparty is dissolved, and the merchant pays the expense of loading and unloading; but if the embargo is only for a short limited time, the voyage shall be performed when it expires; and neither party is liable for damages.

If the master sails to any other port than that agreed on, without necessity, he must sail to the port agreed on at his own expense, and is also liable for any damages in consequence of it.

If a ship is taken by the enemy, and retaken or ransomed, the charterparty continues in force.

If the master transfers the goods from his own ship to another, without necessity, and they perish, he is responsible for the full value, and all charges; but if his own ship is in imminent danger, the goods may be put on board another ship at the risk of the owner.

If a ship is freighted out and home, and a sum agreed on for the whole voyage, nothing becomes due until the return of such ship.

If a certain sum is specified for the homeward voyage, it is due, although the correspondent abroad should have no goods to send home.

A ship was freighted to a particular port and home, a particular freight agreed upon for the homeward voyage, with an option reserved for the correspondent to decline it, unless the ship arrived before a certain day. The master did not go to the port agreed on, and therefore became liable to damages; the obligation being absolute on his part, and conditional only on the part of the freight.

If the goods are damaged without fault of the ship or master, the owner is not obliged to receive them and pay the freight, but he must either receive or abandon the whole; he cannot receive those that are not damaged, and reject the others.

If the goods are damaged through the insufficiency of the ship, the master is liable for the same; but if it is owing to stress of weather he is not accountable.

If part of the goods are thrown overboard, or taken by the enemy, the part delivered pays freight.

The master is accountable for all the goods received on board by himself and mariners, unless they perish by the act of God, or the king's enemies.

The master is not liable for leakage of liquors, nor accountable for contents of packages, unless packed in his presence.

FRESCO, a method of painting in relievo on walls, so as to endure the weather.

It is performed with water-colours on fresh plaster; or a wall laid with mortar not yet dry. This sort of painting has a great advantage by its incorporating with the mortar, and drying along with it, becomes very durable.

The ancients painted on stucco; and we may remark in Vitruvius, what infinite care they took in making the incrustations or plastering of their buildings, to render them beautiful and lasting; though the modern painters find a plaster of lime and sand preferable to it. See Painting.

FRESHES, in sea language, denote the impetuosity of an ebb-tide, increased by heavy rains, and flowing out into the sea, often discolouring it to a considerable distance, and forming a line that separates the two colours, and which may be distinctly perceived for a great length along the coast.

FRET, Frette, in architecture, a kind of knot, or ornament, consisting of two lists or small fillets variously interlaced or interwoven, and running at parallel distances equal to their breadth. See Architecture.

Fret, in heraldry, a bearing composed of six bars, crossed, and variously interlaced. Some call it the true-lover's knot.

Fret, in music, signifies a kind of stop on some instruments, particularly bass-viols and lutes. Frets consists of strings tied round the neck of the instrument, at certain distances, within which such and such notes are to be found.

Fret-work. See **Architecture.**

FRETTY, in heraldry, an appellation given to bearings made up of six, eight, or more bars laid across each other in the manner of frets.

FRIAR, or **Frier**, from the French *frere*, a brother, a term common to monks of all orders, founded on this, that there is a kind of fraternity, or brotherhood, between the several religious persons of the same convent or monastery. Friars are generally distinguished into these four principal branches, viz. 1. Minors, grey friars, or franciscans. 2. Augustines. 3. Dominicans, or black friars. 4. White friars, or carmelites. From these four the rest of the orders descend. See the articles **Franciscans, Augustines**, &c.

Friar observant, is a branch of the franciscan friars; thus called, because they are not combined together in any cloister, convent, or corporation, as the conventuals are; but have bound themselves only to observe the rules of their order more strictly than the conventuals do, from whom they separated, out of a singularity of zeal, living in certain places of their own choosing.

FRICTION, in mechanics, is the resistance which a body meets with from the surface on which it moves.

It is hardly possible to lay down general rules concerning the quantity of friction; since it depends upon a multiplicity of circumstances, as the structure, firmness, elasticity, &c. of the bodies rubbing against each other. Some authors make friction upon an horizontal plane, equal to one third of the weight to be moved; whilst others have found it to be considerably less.

Two objects must however be observed, viz. the loss of power which is occasioned by it, and the contrivances which have been made, and are in use, for the purpose of diminishing its effects.

A body on an horizontal plane should be capable of being moved by the application of the least force; but this is not the case, and the principal causes which render a greater or less quantity of force necessary for it are, 1st, the roughness of the contiguous surfaces; 2dly, the irregularity of the figure, which arises either from the imperfect workmanship, or from the pressure of one body upon the other; 3dly, an adhesion or attraction which is more or less powerful according to the nature of the bodies in question; and 4thly, the interposition of extraneous bodies; such as moisture, dust, &c.

Innumerable experiments have been made for the purpose of determining the quantity of obstruction, or of friction, which is produced in particular circumstances. But the results of apparently similar experiments, which have been made by different experimenters, do not agree; nor is it likely they should, since the least difference of smoothness or polish, or of hardness, or, in short. of any of the various concurring circumstances, produces a different result. Hence no certain and determinate rules can be laid down with respect to the subject of friction.

Mr. Vince, who has made many experiments on friction, infers,

1st, That friction is an uniformly retarding force in hard bodies, not subject to alteration by the velocity; except when the body is covered with cloth, woollen, &c. and in this case the friction increases a little with the velocity.

2dly, Friction increases in a less ratio than the quantity of matter or weight of the body. This increase, however, is different for the different bodies, more or less; nor is it yet sufficiently known, for any one body, what proportion the increase of friction bears to the increase of weight.

3dly. The smallest surface has the least friction, the weight being the same. But the ratio of the friction to the surface is not yet accurately known.

Mr. Vince's experiments consisted in determining how far the sliding bodies would be drawn in given times, by a weight hanging freely over a pulley. This method would both show him if the friction was a constant retarding force, and the other conclusions above stated. For as the spaces described by any constant force, in given times, are as the squares of the times, and as the weight drawing the body is a constant force, if the friction, which acts in opposition to the weight, should also be a constant force, then their difference, or the force by which the body is urged, will also be constant, in which case the spaces described ought to be as the squares of the times, which happened accordingly in the experiments.

Mr. Vince adds some remarks on the nature of the experiments which have been made by others. These, he observes, the authors "have instituted to find what moving force would just put a body at rest in motion, and they concluded thence that the accelerative force was then equal to the friction; but it is manifest, that any force which will put a body in motion must be greater than the force which opposes its motion, otherwise it could not overcome it: and hence, if there were no other objections than this, it is evident that the friction could not be very accurately obtained; but there is another objection, which totally destroys the experiment, so far as it tends to show the quantity of friction, which is the strong cohesion of the body to the plane when it lies at rest." This he confirms by several experiments, and then adds: "From these experiments, therefore, it appears how very considerable the cohesion was in proportion to the friction when the body was in motion; it being in one case almost $\frac{1}{3}$, and in another it was found to be very nearly equal to the whole friction. All the conclusions, therefore, deduced from the experiments which have been instituted to determine the friction, from the force necessary to put a body in motion, (and I have never seen any described but upon such a principle) have manifestly been totally false; as such experiments only show the resistance which arises from the cohesion and friction conjointly." Philos. Trans. vol. 75, pa. 165.

If a body is laid upon another body, and soon after is moved along the surface of it, a less force will be found sufficient for the purpose, than if the body be left some

time at rest before it be moved. This arises principally from an actual change of figure, which is produced in a longer or shorter time, according to the nature of the bodies. Thus the maximum of adhesion between wood and wood takes place in a few minutes' time; between metal and metal it takes place almost immediately. A hard and heavy body laid upon a softer one will sometimes continue to increase its adhesion for days and weeks.

When a cubic foot of soft wood of eight pounds weight is to be moved upon a smooth horizontal plane of soft wood, at the rate of three feet per second, the power which is necessary to move it, and which is equivalent to the friction, amounts to between 1-4th and 1-3d of the weight of the cube. When the wood is hard, the friction amounts to between 1-7th and 1-8th of the weight of the cube.

In general the softer or the rougher the bodies are, the greater is their friction. Yet when two pieces of metal, extremely well polished, are laid one upon the other with an ample surface of contact, they adhere to each other much more forcibly than when they are not so well polished.

Iron or steel moves easiest in brass. Other metals acting against each other produce more friction.

The friction, cæteris paribus, increases with the weight of the superincumbent body, and almost in the same proportion.

The friction or obstruction which arises from the bending of ropes about machines, is influenced by a variety of circumstances, such as their peculiar quality, the temperature of the atmosphere, and the diameter or curvature of the surface to which they are to be adapted. But when other circumstances remain the same, the difficulty of bending a rope increases with the square of its diameter, as also with its tension, and it decreases according as the radius of the curvature of the body to which it is adapted, increases.

Of the simple mechanical powers the lever is the least subject to friction.

In a wheel, the friction upon the axis is, as the weight that lies upon it, as the diameter of the axis, and as the velocity of the motion. But upon the whole, this sort of friction is not very great, provided the machine is well executed. In common pulleys, especially those of a small size, the friction is very great. It increases in proportion as the diameter of the axis increases, as the velocity increases, and as the diameter of the pulley decreases. With a moveable tackle, or block of five pulleys, a power of 150 pounds will barely be able to draw up a weight of 500 pounds.

The screw is subject to a great deal of friction; so much so that the power which must be applied to it, in order to produce a given effect, is at least double that which is given by the calculation independent of friction. But the degree of friction in the screw is influenced considerably by the nature of the construction; for much of it is owing to the tightness of the screw, to the distance between its threads, and to the shape of the threads; the square threads producing upon the whole, less friction than those which are sharp.

The friction which attends the use of the wedge, exceeds in general that of any other mechanical power. Its quantity depends so much upon the nature of the body upon which the wedge acts, besides other circumstances, that it is impossible to give even an approximate estimate of it.

The friction of mechanical engines not only diminishes the effect, or, which is the same thing, occasions a loss of power; but is attended with the corrosion and wear of the principal parts of the machine, besides producing a considerable degree of heat, and even actual fire; it is therefore of great importance in mechanics to contrive means capable of diminishing, if not of quite removing, the effects of friction.

In compound engines, the obstruction which arises from friction can be ascertained only by means of actual experiments. An allowance, indeed, may be made for each simple component mechanical power; but the error in estimating the friction of any one single power is multiplied and increased so fast by the other parts, that the estimate generally turns out very erroneous. Besides, much depends on the execution of the work; the quality of which cannot be learned but by experience. Novices are generally apt to expect too much or too little from any mechanism. In general it can only be said, that in compound engines, at least one-third of the power is lost on account of the friction.

The methods of obtaining the important object of diminishing the friction, are of two sorts, viz. either by the interposition of particular unctuous or oily substances between the contiguous moving parts, or by particular mechanical contrivances.

Olive-oil is the best, and perhaps the only substance that can be used in small works, as in watches and clocks, when metal works against metal. But in large works the oil is liable to drain off, unless some method is adopted to confine it. Therefore for large works tallow is mostly used, or grease of any sort; which is useful for metal, as well as for wood. In the last case tar is also frequently used.

In delicate works of wood, viz. when a piece of wood is to slide into or over wood, and when a wooden axis is to turn into wood, the fine powder of what is commonly called black-lead, when interposed between the parts, eases the motion considerably, and is at the same time a clean and durable substance.

Though olive-oil is the best and the only substance that is used for delicate mechanisms; yet it is far from being free from objections. Oil, when in contact with brass, is liable to grow rancid, in which state it slowly corrodes the brass. In different temperatures it becomes more or less fluid; but upon the whole it grows continually thicker, and of course less fit to ease the motion of the parts, &c. Trifling as those defects may at first sight appear, they are however of such moment in delicate works, that in the greatly improved state to which watchwork has been brought, the changeable quality of the oil seems at present to be the principal, if not the only impediment to the perfection of chronometers.

The mechanical contrivances which have been made, and are in use, for the purpose of diminishing the effects of friction, consist either in avoiding the contact of such bodies as produce much friction, or in the interposition of rollers, viz. cylindrical bodies, between the moving parts of machines, or between moving bodies in general. Such cylinders derive, from their various size and ap-

plication, the different names of rollers, friction-wheels, and friction-rollers.

Thus in mill-work and other large machines, the wooden axes of large wheels terminate in iron gudgeons, which turn in wood, or more frequently in iron or brass, which construction produces less friction than the turning of wood in wood. In the finest sort of watch-work the holes are jewelled, viz. many of the pivots of the wheels, &c. move in holes made in rubies, or topazes, or other hard stone, which, when well finished, are not liable to wear, nor do they require much oil.

In order to understand the nature of rollers, and the advantage with which their use is attended, it must be considered, that when a body is dragged over the surface of another body, the inequalities of the surfaces of both bodies meet and oppose each other, which is the principal cause of the friction or obstruction; but when one body, such as a cask, a cylinder, or a ball, is rolled upon another body, the surface of the roller is not rubbed against the other body, but is only successively applied to, or laid on, the other, and is then successively lifted up from it. Therefore, in rolling, the principal cause of friction is avoided, besides other advantages: hence a body may be rolled upon another body, when the shape admits of it, with incomparably less exertion than that which is required to drag it over the surface of that other body. In fact, we commonly see large pieces of timber, and enormous blocks of stone, moved upon rollers, that are laid between them and the ground, with ease and safety, when it would be almost impossible to move them otherwise.

The form and disposition of friction-wheels is represented by fig. 94, Plate LXIV. Miscel. which exhibits a front view of the axis of a large wheel, which moves between the friction-wheels A, B, C. Here the end of the axis (and the same thing must be understood of the opposite extremity of the axis) instead of moving in a hole, moves between the circumferences of three wheels, each of which is moveable upon its own axis, and is unconnected with the others. Now if the end of the axis turned in a hole, the surface of the hole would stand still, and the surface of the axis would rub against it; whereas, when the axis moves between the circumferences of the wheels A, B, C, its surface does not rub against, but is successively applied to the circumferences of those wheels; so that this sort of motion has the same advantage over the turning of the axis in a hole, that the moving of a heavy body upon rollers has over the simple method of dragging it upon the ground. In this construction the contact of the axis moves the wheels A, B, C, round their axis, where indeed some friction must unavoidably take place, but that friction is very trifling; for if the circumference of the axis be to that of each wheel as 1 to 20, the axis must make 20 revolutions whilst the friction-wheels will turn round once only.

A few years ago the same principle was applied in a very ingenious manner, by Mr. J. Garnett, then of Bristol, to pulleys, and other sorts of circular motion round an axis, for which he obtained a patent. The use of this application has proved very advantageous, especially on board of ships, where it has been found, that with a set of Mr. Garnett's pulleys, three men were able to draw as much weight as five men were barely able to accomplish with a similar set of common pulleys.

One of these pulleys is represented by fig. 95, Plate LXIV. Miscel. where the shaded part B B B is the pulley, A is the axis, round which are the cylindrical rollers, which are situated between the axis and the inside cavity of the pulley. The ends of the axis A are fixed in a block, after the usual manner. Every one of the rollers has an axis, the extremities of which turn in holes made in two brass or iron flat rings.

After having given a general explanation of the action of rollers, the advantage which Mr. Garnett's pulleys must have over those of the common sort, needs no farther illustration. We shall, however, only observe, that the friction of the pivots of each roller in the holes of the brass rings is very inconsiderable; for those holes are made rather large, the use of the axes to the rollers being only to prevent their running one against the other. Nor does the addition of weight upon the pulley increase that friction, for the addition of weight upon the pulley will press the rollers harder upon the axis A, but not upon their own axes, as may be easily understood by inspecting the figure. See Brewster's edition of Ferguson's Lectures.

Friction may be considered chemically as a source of caloric. Fires are often kindled by rubbing pieces of dry wood smartly against one another. It is well known that heavy loaded carts sometimes take fire by the friction between the axle-tree and the wheel. Now in what manner is the caloric evolved or accumulated by friction? Not by increasing the density of the bodies rubbed against each other, as happens in cases of percussion, for heat is produced by rubbing soft bodies against each other, the density of which therefore cannot be increased by that means, as any one may convince himself by rubbing his hand smartly against his coat. It is true, indeed, that heat is not produced by the friction of liquids; but then they are too yielding to be subjected to strong friction. It is not owing to the specific caloric of the rubbed bodies decreasing; for Count Rumford found that there was no sensible decrease, nor, if there was a decrease, would it be sufficient to account for the vast quantity of heat which is sometimes produced by friction.

Count Rumford took a cannon cast solid and rough, as it came from the foundery; he caused its extremity to be cut off, and formed, in that part, a solid cylinder attached to the cannon $7\frac{3}{4}$ inches in diameter, and $9\frac{8}{10}$ inches long. It remained joined to the rest of the metal by a small cylindrical neck. In this cylinder a hole was bored 3.7 inches in diameter and 7.2 inches in length. Into this hole was put a blunt steel borer, which by means of horses was made to rub against its bottom: at the same time a small hole was made in the cylinder perpendicular to the bore, and ending in the solid part a little beyond the end of the bore. This was for introducing a thermometer to measure the heat of the cylinder. The cylinder was wrapt round with flannel to keep in the heat. The borer pressed against the bottom of the hole with a force equal to about 10,000lbs. avoirdupois, and the cylinder was turned round at the rate of 32 times in a minute. At the beginning of the experiment the tempera-

ture of the cylinder was 60°; at the end of 30 minutes, when it had made 960 revolutions, its temperature was 130°. The quantity of metallic dust or scales produced by this friction amounted to 837 grains. Now if we were to suppose that all the caloric was evolved from these scales, as they amounted to just $\frac{1}{941}$ part of the cylinder, they must have given out 948° to raise the cylinder 1°, and consequently 66360° to raise it 70° or to 130°, which is certainly incredible.

Neither is the caloric evolved during friction, owing to the combination of oxygen with the bodies themselves, or any part of them. By means of a piece of clock-work, Mr. Pictet made small cups (fixed on the axis of one of the wheels), to move round with considerable rapidity, and he made various substances rub against the outsides of these cups, while the bulb of a very delicate thermometer placed within them marked the heat produced. The whole machine was of a size sufficiently small to be introduced into the receiver of an air-pump. By means of this machine a piece of adamantine spar was made to rub against a steel cup in air: Sparks were produced in great abundance during the whole time, but the thermometer did not rise. The same experiment was repeated in the exhausted receiver of an air-pump (the manometer standing at four lines); no sparks were produced, but a kind of phosphoric light was visible in the dark. The thermometer did not rise. A piece of brass being made to rub in the same manner against a much smaller brass cup in air, the thermometer (which almost filled the cup) rose 0.3°, but did not begin to rise till the friction was over. This shows us that the motion produced in the air carried off the caloric as it was evolved. In the exhausted receiver it began to rise the moment the friction began, and rose in all 1.2°. When a bit of wood was made to rub against the brass cup in the air, the thermometer rose 0.7°, and on substituting also a wooden cup, it rose 2.1°, and in the exhausted receiver 2.4°, and in air condensed to $1\frac{3}{4}$ atmospheres it rose 0.5°.

If these experiments should not be thought conclusive, there are others, which will not leave a doubt that the heat produced by friction is not connected with the decomposition of oxygen gas. Count Rumford contrived, with his usual ingenuity, to inclose the cylinder above described in a wooden box filled with water, which effectually excluded all air, as the cylinder itself and the borer were surrounded with water, and at the same time did not impede the motion of the instrument. The quantity of water amounted to 18.77lbs. avoirdupois, and at the beginning of the experiment was at the temperature of 60°. After the cylinder had revolved for an hour at the rate of 32 times in a minute, the temperature of the water was 107°; in 30 minutes more it was 178°; and in two hours and 30 minutes after the experiment began, the water actually boiled. According to the computation of Count Rumford, the caloric produced would have been sufficient to heat 26.58lbs. avoirdupois of ice-cold water boiling hot; and it would have required nine wax candles of a moderate size, burning with a clear flame all the time the experiment lasted, to have produced as much heat. In this experiment all access of water into the hole in the cylinder where the friction took place was prevented. But in another experiment, the result of which was precisely the same, the water was allowed free access.

The caloric then, which appears in consequence of friction, is neither produced by an increase of the density, nor by an alteration in the specific caloric of the substances exposed to friction, nor is it owing to the decomposition of the oxygen of the atmosphere. Whence then is it derived? This question cannot at present be answered: but this is no reason for concluding with count Rumford, that there is no such substance as caloric at all, but that it is merely a peculiar kind of motion; because other facts demonstrate the existence of caloric as a substance. Was it possible to prove that the accumulation of caloric by friction is incompatible with its being a substance, in that case count Rumford's conclusion would be a fair one; but this surely has not been done. We are certainly not yet sufficiently acquainted with the laws of the motion of caloric, to be able to affirm with certainty that friction cannot cause it to accumulate in the bodies rubbed. This we know at least to be the case with electricity. Nobody has been hitherto able to demonstrate in what manner it is accumulated by friction; and yet this has not been thought a sufficient reason to deny its existence.

Indeed there seems to be a very close analogy between caloric and electric matter. Both of them tend to diffuse themselves equally, both of them dilate bodies, both of them fuse metals, and both of them kindle combustible substances. See ELECTRICITY.

Mr. Achard has proved, that electricity can be substituted for caloric even in those cases where its agency seems peculiarly necessary; for he found that by constantly supplying a certain quantity of the electric fluid, eggs could be hatched just as when they are kept at the temperature of 103°. An accident indeed prevented the chickens from actually coming out, but they were formed and living, and within two days of bursting their shell. Electricity has also a great deal of influence on the heating and cooling of bodies. Mr. Pictet exhausted a glass globe, the capacity of which was 1200.199 cubic inches, till the manometer within it stood at 1.75 lines. In the middle of this globe was suspended a thermometer, which hung from the top of a glass rod fixed at the bottom of the globe, and going almost to its top. Opposite to the bulb of this thermometer two lighted candles were placed, the rays of which, by means of two concave mirrors, were concentrated on the bulb. The candles and the globe were placed on the same board, which was supported by a non-conductor of electricity. Two feet and a half from the globe there was an electrifying machine, which communicated with a brass ring at the mouth of the globe by means of a metallic conductor. This machine was kept working during the whole time of the experiment; and consequently a quantity of electric matter was constantly passing into the globe, which, in the language of Pictet, formed an atmosphere not only within it, but at some distance round, as was evident from the imperfect manner in which the candles burned. When the experiment began the thermometer stood at 49.8°. It rose to 70.2° in 732″. The same experiment was repeated, but no electric matter thrown in; the thermometer rose from 49.8° to 70.2° in 1050″; so that the electricity hastened the heating almost a third. In the first experiment the thermometer rose only to 71.3°, but in the second it rose to 77°. This difference was doubtless

owing to the candles burning better in the second than first experiment; for in other two experimects made exactly in the same manner, the maximum was equal both when there was and was not electric matter present. These experiments were repeated with this difference, that the candles were now insulated, by placing their candlesticks in vessels of varnished glass. The thermometer rose in the electrical vacuum from 52.2° to 74.7° in 1050″; in the simple vacuum in 965″. In tbe electrical vacuum the thermometer rose to 77°; in the simple vacuum to 86°. It follows from these experiments, that when the globe and the candles communicated with each other, electricity hastened the heating of the thermometer; but that when they were insulated separately, it retarded it. One would be apt to suspect the agency of electricity in the following experiment of Mr. Pictet: into one of the brass cups formerly described, a small quantity of cotton was put to prevent the bulb of the thermometer from being broken. As the cup turned round, two or three fibres of the cotton rubbed against the bulb, and without any other friction the thermometer rose five or six degrees. A greater quantity of cotton being made to rub against the bulb, the thermometer rose 15°.

FRIDSTOL, mentioned in our ancient writers among the immunities granted to churches, signifies a seat, chair, or place of peace and security, where criminals might find safety and protection: of these there were many in England, but the most famous was at Beverley, and that in St. Peter's church at York, granted by charter of king Henry I.

FRIEND, or Quaker. A society of dissenters from the church of England, obtained the latter appellation in the middle of the seventeenth century; the former they had before applied, and continue to apply, to themselves. The first preacher of this society was George Fox, a man of humble birth, and illiterate. The undertaking to which he considered himself called, that of promulgating a more simple and spiritual form of christianity than any of those which prevailed, and of directing the attention of christians to immediate Revelation, required little more reading than that of the Bible. A constant reference to the scriptures, with great zeal, courage, and perseverance, in preaching and suffering. did more than literature could have done, to spread his doctrine among the middle and lower classes. By those who treated religion scientifically, it was, with a few exceptions, more warmly opposed than sufficiently investigated. Arguments of civil coercion, of which the Friends bad a full, and from their stiffness more than a common share, have been found to recommend, instead of repressing dissent. A more liberal and laudable treatment of conscientious scruples has succeeded; and it may be now said, in a better sense, respecting religion, Sub judice lis est.

The most prominent feature in the Friends' view of christianity is this: seeing, no man knoweth the Father but the Son, and he to whomsoever the Son will reveal him, and seeing the revelation of the Son is in and by the Spirit; therefore the testimony of the Spirit is that alone by which the true knowledge of God is revealed. In this doctrine they agree in substance with the church of England, and all others who acknowledge the efficacy of grace. For in whatever way this is afforded to christians, it is powerfully given to know and to do the will of God; and the communication of grace may be termed, in strict consistency with the sense of the New Testament, a revelation of Christ in the Spirit. The Friends receive the Holy Scriptures as having proceeded from the revelations of the Holy Spirit; they account them the secondary rule for christians, subordinate to the word, and therefore not the word of God. According to these they profess their belief in one God, as Father, Word, and Holy Spirit; in one mediator, the word made flesh, Jesus Christ; in the conception, birth, life, miracles, death, resurrection, and ascension of Jesus; and in the remission of sins thereby purchased for the whole world of fallen mankind. Christ's redemption they believe to be perfected in us by his second coming in Spirit; in which they who obey him are, through the obedience of faith, restored from their state of alienation, and reconciled to God. They affirm, that for this end there is given to every man a measure of the light of Christ, (called by their early preachers the light within) a manifestation of the spirit to profit withal; which discovers sin, reproves for it, leads out of it, and if not resisted, will save from it, and lead on the christian to perfection. In public worship they profess to wait on God in this gift, in order to have their conditions made manifest, in silence and retirement of mind. They look for an extraordinary motion of it for vocal worship, and considering the qualification of a minister as a further gift which God confers, and of which the church ought to judge in the same spirit, they do not limit its exercise to any description of persons. They suffer some inconvenience hereby, as they acknowledge, but they prefer bearing this to the establishing of any form of worship, save the forementioned, waiting in silence. They do not baptize formally, or use the sign of the communion; they say the one has ceased as to obligation, and that the true administration of the other is by the spirit alone.

They deem it unlawful for christians to swear at all; and their affirmation in civil causes is made legal, instead of an oath. They refuse to "learn war or to lift up the sword," as well as to contribute directly to military proceedings. Yet as they inculcate implicit submission, actively or passively, to Cæsar, they neither resist nor evade the legal appropriation of their substance by him, as well to these as to ecclesiastical purposes. Against the claims of the clergy, as well as many other things apparently lawful, they say in their phraseology they have a testimony to bear.

Some peculiarities, well enough known, mark them out from their fellow citizens. Simplicity in dress, in some instances, nearly amounting to an adherence to their original, though not prescribed, costume; simplicity of language, *thou* to one person, and without compliments; simplicity in their manners of living; the non-observance of fasts and feasts; the rejection of those which they call the unchristian names of days and months; and the renunciation of the theatres and other promiscuous amusements, gaming, and the usual outward signs of mourning and rejoicing, may be considered as their Shibboleth.

They marry among themselves by a ceremony or contract, religiously conducted. and bury their dead in the most simple manner. They maintain their poor, and enforce their own rules, by means of an excellent system of discipline, founded by G. Fox. They receive ap-

proved applicants into their society by an act of monthly meeting, or particular congregation, and without subscription of articles. They disown in the same manner, after repeated admonition, not officially only, but actually extended, to offenders against morality, or their peculiar rules. The latter may be seen in a book entitled, "Extracts from the Minutes and Advices of the Yearly Meeting of Friends, held in London, from its first institution:" their principles and doctrines in Barclay's Apology, and their history in a large work by William Sewel.

FRIEZE, FREEZE, or FRIZE. See ARCHITECTURE.

FRIGATE, among seamen, a ship of war, light built, and that is a good sailer. A frigate has commonly two decks, whence that called a light frigate is a frigate with only one deck. All ships of war that carry from 20 guns to 50 guns are called frigates.

FRIGATOON, a Venetian vessel, commonly used in the Adriatic sea, with a square stern, and carrying only a mainmast, mizen, and bowsprit.

FRILAZIN, the name of a class or rank of people among the Anglo-Saxons, consisting of those who had been slaves, but had either purchased, or by some other means obtained, their liberty. Though these were in reality free men, they were not considered as of the same rank and dignity with those who had been born free, but were still in a more ignoble condition, and dependent either on their former masters or on some new patrons. This custom the Anglo Saxons seem to have derived from their ancestors in Germany, among whom those who had been made free did not differ much in point of dignity or importance in the state from those who continued in servitude. This distinction between those who have been made free, and those who enjoy freedom by descent from a long race of free men, still prevails in many parts of Germany; and particularly in the original seats of the Anglo-Saxons. Many of the inhabitants of towns and cities in England, in this period, seem to have been of this class of men, who were in a kind of middle state between slaves and freemen.

FRINGELLA, in ornithology, a genus belonging to the order of passeres. The bill is conical, straight, and sharp-pointed. There are no less than 108 species comprehended under this genus, distinguished principally by varieties in their colour. The following are the most remarkable.

1. The carduelis, or goldfinch, with the quill feathers red forwards, and the outermost without any spots; the two outermost are white in the middle, as the rest are at the point. The young bird, before it moults, is grey on the head; and hence it is termed by the bird-catchers a grey-pate. There is a variety of goldfinches called by the London bird-catchers a cheverel, from the manner in which it concludes its jerk. It is distinguished from the common sort by a white streak, or by two, sometimes three, white spots under the throat. The note of the goldfinch is very sweet, and they are much esteemed on that account, as well as for their great docility. Towards winter, they assemble in flocks, and feed on seeds of different kinds, particularly those of the thistle. They are fond of orchards, and frequently build in an apple or pear-tree; the nest is very elegantly formed of fine moss, liverworts, and bents, on the outside; lined first with wool or hair, and then with the goslin or cotton of the sallow. The goldfinch lays five white eggs, marked with deep purple spots on the upper end, and has two broods in the year. When kept in cages, they are commonly fed much on hemp-seed, which they eat freely, but which is said to make them grow black, and lose both their red and yellow. The goldfinch is a long-lived bird, often attaining the age of 20 years. This species is numerous throughout Europe; it is also met with both in Asia and Africa, but less common in those countries.

2. The cælebs, or chaffinch, has black limbs, and the wings white on both sides; the three first feathers of the tail are without spots, but two of the chief are obliquely spotted. It has its name from delighting in chaff. This species entertains us agreeably with its song very early in the year, but towards the end of the summer assumes a chirping note. Both sexes continue with us the whole year. What is very singular in Sweden, the female quits that country in September, migrating in flocks into Holland, leaving their mates behind: in the spring they return. In Hampshire Mr. White has observed sometimes vast flocks of females with scarcely any males among them. Their nest is as elegantly constructed as that of the goldfinch, and of much the same materials, only the inside has the addition of some large feathers. They lay four or five eggs of a dull white colour, tinged and spotted with deep purple. They are caught in plenty in flight-time.

3. The montifringilla, or brambling, has a yellow bill tipt with black; the head, hind part of the neck, and back, are black; the throat, fore part of the neck, and breast, pale rufous orange; lower part of the breast and belly white; the quill feathers brown, with yellowish edges; the tail a little forked; the legs grey. This species migrates into England at certain seasons, but does not build there. It is frequently found among chaffinches, and sometimes comes in vast flocks. They are also seen at certain times in vast clouds in France, insomuch that the ground has been quite covered with their dung, and more than 600 dozen were killed each night. They are said to be particularly fond of beech mast, but will also eat seeds of various other kinds. Their flesh is eaten by many, but is apt to prove bitter. They are said to breed about Luxemburgh, making their nests on the tall fig-trees, composed of long moss without, and lined with wool and feathers within; the eggs are four or five in number, yellowish, and spotted; and the young are fledged at the end of May. This species is found more or less throughout Europe, and is common in the pine forests of Russia and Siberia, but those of the last are darker in colour and less in size.

4. The domestica, or sparrow, has the prime feathers of the wings and tail brown, the body variegated with grey and black, and a single white streak on the wings. These well-known birds are proverbially salacious, and have three broods in a year. They are every where common about our houses, where they build in every place they can find admittance to; under the roof, at the corner of the brick-work, or in holes of the wall. They make a slovenly nest; generally a little hay ill put together, but lined well with feathers, where they lay five or six eggs of a reddish white colour spotted with brown. They will sometimes build in the neighbouring trees, in which case they take more pains with the nest; and not

unfrequently they expel the martins from theirs, to save the trouble of constructing one of their own. The sparrow, from frequenting only habitations and parts adjacent, may be said to be chiefly fed from human industry; for, in spite of every precaution, it will partake with the pigeons, poultry, &c. in the food thrown out to them, grain of all kinds being most agreeable to its taste, though it will eat refuse from the kitchen of most kinds. It is a familiar but crafty bird, and will not so easily come into a snare as many others. In autumn they often collect into flocks, and roost in numbers on the neighbouring trees, when they may be shot by dozens, or at night caught in great numbers by a bat fowling-net.

5. The spinus, or siskin, has the prime feathers of the wings yellow in the middle, and the four first chief tail-feathers without spots; but they are yellow at the base, and black at the points. Mr. Willoghby tells us, that this is a song-bird; that in Sussex it is called the barley-bird, because it comes to them in barley-seed time. We are informed that it visits these islands at very uncertain times, like the gross-beak, &c. It is to be met with in the bird-shops in London; and being rather a scarce bird, sells at a higher price than the merit of its song deserves: it is known there by the name of the aberdavine. It is a very tame and docile species, and is often kept and paired with the Canary-bird, with which it breeds freely. The bird-catchers have a notion of its coming out of Russia. Dr. Kramer informs us, that this bird conceals its nest with great art; and though there are infinite numbers of young birds in the woods on the banks of the Danube, which seem just to have taken flight, yet no one could discover the nest.

6. The linota, or linnet, has the bottom of the breast of a fine blood-red, which heightens as the spring advances. These birds are much esteemed for their song. They feed on seeds of different kinds, which they peel before they eat; the seed of the linum or flax is their favourite food; whence the name of the linnet tribe. They breed among furze and white thorn; the outside of their nest is made with moss and bents, and lined with wool and hair. They lay five whitish eggs, spotted like those of the goldfinch.

7. The cannabina, or greater red-pole, is less than the common linnet, and has a blood-coloured spot on the forehead, and the breast of the male is tinged with a fine rose-colour. It is a common fraud in the bird-shops in London, when a male bird is digtinguished from the female by a red-breast, as in the case of this bird, to stain or paint the feathers, so that the deceit is not easily discovered, without at least close inspection. These birds are frequent on the coasts of Britain, and are often taken in flight-time near London: it is a familiar bird, and is chereful in five minutes after it is caught.

8. The linaria, or lesser red-pole, is about half the size of the last, with a rich spot of purplish red on the forehead; the breast is of the same colour, but less bright. Mr. Pennant mentions an instance of this bird being so tenacious of her nest, as to suffer herself to be taken off by the hand, and that when released she would not forsake it. This species is known about London by the name of stone red-pole. Linnæus, Kramer, and others, mention its being very fond of the seeds of alder. Whole flocks of them, mixed with the siskin, frequent places where alders grow, for the sake of picking the catkins: they generally hang like the titmouse, with the back downwards; and in this state are so intent on their work, that they may be entangled one after another by dozens, by means of a twig, smeared with bird-lime, fastened to the end of a fishing-rod or other long pole. This species seems to be in plenty throughout Europe, from the extreme parts of Russia on the one hand to Italy on the other; is very common in Greenland, and was also met with by our late voyagers at Aoonalashka. In America it is likewise well known. Hence it seems to be a bird common to the whole of the northern part of the globe without exception.

9. The montium, or twite, is about the size of a linnet. It has the feathers of the upper part of the body dusky, those on the head edged with ash-colour, the others with brownish red: the rump is pale crimson; the wings and tail are dusky, the tips of the greater coverts and secondaries whitish; the legs pale brown. The female wants the red mark on the rump. Twites are taken in the flight-season near London, along with other linnets. It is probable that the name has been taken from their twittering note, having no music in it; and indeed the bird-catchers will tell, at some distance, whether there are any twites mixed among linnets merely from this circumstance. The twite is supposed to breed in the more northern parts of England.

10. The amandava, or amaduvade bird, is about the size of a wren. The colour of the bill is of a dull red; all the upper parts are brown, with a mixture of red: the under the same, but paler, the middle of the belly darkest; all the feathers of the upper wing-coverts, breast, and sides, have a spot of white at the tip: the quills are of a grey brown; the tail is black, and the legs are of a pale yellowish white. It inhabits Bengal, Java, Malacca, and other parts of Asia.

11. The senagala, or Senegal finch, is a species very little larger than a wren. The bill is reddish, edged all round with brown, and beneath the under mandible a line of brown quite to the tip: the same also is seen on the ridge of the upper mandible; the upper parts of the body are of a vinaceous red colour; the lower parts, with the thighs and under tail-coverts, of a greenish brown; the hind part of the head and neck, the back, scapulars, and wing-coverts, are brown; the tail is black; and the legs are pale grey. It inhabits Bengal; and, with the former species, feeds on millet. This affords the natives an easy method of catching them: they have no more to do than to support a large hollowed gourd, the bottom uppermost, on a stick, with a string leading to some covered place, and strewing under it some millet; the little birds, hastening in numbers to pick it up, are caught beneath the trap, by the stick being pulled away by the observer at a distance. The females are said to sing nearly as well as the males. They are familiar birds; and when once used to the climate, will frequently live five or six years in a cage. They have been bred in Holland by the fanciers of birds. See Plate LX. Nat. Hist. fig. 209.

12. The canaria, or canary-bird, has a whitish body and bill, with the prime feathers of the wings and tail greenish. It was originally peculiar to those islands to which it owes its name; the same that were known to

the ancients by the addition of the Fortunate. Though the ancients celebrate the island of Canaria for the multitude of birds, they have not mentioned any in particular. It is probable then, that this species was not introduced into Europe till after the second discovery of these islands, which was between the 13th and 14th centuries. We are uncertain when it first made its appearance in that quarter of the globe. Belon, who wrote in 1555, is silent in respect to these birds; Gesner is the first who mentions them; and Aldrovand speaks of them as rarities, observing that they were very dear, on account of the difficulty attending the bringing them from so distant a country, and that they were purchased by people of rank alone. They are still found on the same spot to which we were first indebted for the production of such charming songsters; but they are now become so very numerous, that we are under no necessity of crossing the ocean for them. The canary-bird will prove fertile with the siskin and goldfinch; but in this case the produce, for the most part, proves sterile: the pairs succeed best when the hen-bird is the canary, and the cock of the opposite species. It will also prove prolific with the linnet, yellow-hammer, chaffinch, and even the house sparrow; but the male canary-bird will not assimilate with the female of these birds; the hen must be ever of the canary species, and the young of these mostly prove male birds. This bird is said by some to live 10 or 15 years; by others as far as 18.

13. The maja, or cubafinch, is about three and one quarter inches long, is found in Cuba, and feeds principally on rice. See Plate LX. Nat. Hist. fig. 210.

FRIT, or Fritt, in the glass manufacture, is the matter or ingredients of which glass is to be made, when they have been calcined or baked in a furnace. A salt drawn from the ashes of the plant kali or from fern, or other plants, mixed with sand or flint, and baked together, makes an opaque mass, called by glass-men frit; probably from the Italian frittare, to fry; or because the frit when melted runs into lumps, like fritters, called by the Italians fritelli. Frit by the ancients was called ammonitrum, from ἁμμ, sand, and νιτρον, nitre; under which name it is described by Pliny thus: Fine sand from the Volturnian sea, mixed with three times the quantity of nitre, and melted, makes a mass called ammonitrum; which being rebaked makes pure glass. Frit, Neri observes, is only the calx of the materials which makes glass; which, though they might be melted, and glass be made without thus calcining them, yet it would take up much more time. This calcining, or making of frit, serves to mix and incorporate the materials together, and to evaporate all the superfluous humidity. The frit, once made, is readily fused and turned into glass.

There are three kinds of frit: the first crystal frit, or that for crystal or clear glass, is made with salt of pulverine and sand. The second and ordinary frit is made of the bare ashes of pulverine or barilla, without extracting the salt from them. This makes the ordinary white or crystal glass. The third is frit for green glasses, made of common ashes, without any preparation. This last frit will require 10 or 12 hours baking. The materials in each are to be finely powdered, washed, and searced; then equally mixed, and frequently stirred together in the melting pot.

FRITH, in its most usual acceptation, signifies an arm of the sea: such are the frith of Forth or of Edinburgh, the frith of Clyde, Murray frith, &c.

FRITILLARIA, fritillary, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 10th order, coronariæ. The corolla is hexapetalous and campanulated, with a nectariferous cavity above the heel in each petal; the stamina are as long as the corolla. There are five species, all of them bulbous-rooted flowery perennials, producing annual stalks from about one foot to a yard or more high, terminated by large, bell-shaped, liliaceous flowers, of a great variety of colours. They are all propagated by offsets, which they furnish abundantly from the sides of the roots, and which may be separated every second or third year; they are hardy plants, and will thrive in any of the common borders. The crown-imperial is well known.

FRIZING *of cloth*, a term in the wollen manufactory, applied to the forming of the nap of cloth or stuff into a number of little hard burrs or prominences, covering almost the whole ground.

Some cloths are only frized on the back-side, as black cloths; others on the right side, as coloured and mixed cloths, rateens, bays, freezes, &c. Frizing may be performed two ways: one with the hand, that is, by means of two workmen, who conduct a kind of plank that serves for a frizing instrument. The other way is by a mill, worked either by water or a horse, or sometimes by men. This latter is esteemed the better way of frizing, the motion being uniform and regular, the little knobs of the frizing are formed more equably and regularly. The structure of this useful machine is as follows:

The three principal parts are the frizer or crisper, the frizing-table, and the drawer or beam. The two first are two equal planks or boards, each about 10 feet long, and 15 inches broad, differing only in this, that the frizing-table is lined or covered with a kind of coarse woollen stuff, of a rough sturdy nap; and the frizer is incrustated with a kind of cement composed of glue, gum arabic, and a yellow sand, with a little aqua vitæ or urine. The beam or drawer, thus called because it draws the stuff from between the frizer and the frizing-table, is a wooden roller, beset all over with little, fine, short points, or ends of wire, like those of cards used in carding of wool.

The disposition and use of the machine is thus: The table stands immoveable, and sustains the cloth to be frized, which is laid with that side uppermost on which nap is to be raised: over the table is placed the frizer, at such a distance from it as to give room for the stuff to be passed between them, so that the frizer, having a very slow semicircular motion, meeting the long hairs or naps of the cloth, twists and rolls them into little knobs or burrs, while at the same time the drawer, which is continually turning, draws away the stuff from under the frizer, and winds it over its own points.

All that the workman has to do while the machine is going, is to stretch the stuff on the table as fast as the drawer takes it off: and from time to time to take off the stuff from the points of the drawer. The design of [illegible]ing the frizing-table [illegible] with stuff of a [illegible]

stubby nap, is that it may detain the cloth between the table and the frizer long enough for the grain to be formed, that the drawer may not take it away too readily, which must otherwise be the case, as it is not held by any thing at the other end. It is unnecessary to say any thing particular of the manner of frizing stuffs with the hand, it being the aim of the workmen to imitate as near as they can, with their wooden instrument, the slow, equable, and circular motion of the machine: it needs only be added, that their frizer is but about two feet long and one broad; and that, to form the nap more easily, they moisten the surface of the stuff lightly with water mingled with whites of eggs or honey.

FROG. See RANA.

FROG-FISH of Surinam, a very singular animal, of which there is no specimen in the British or any public museum. In Surinam these fishes are called jakjés. They are cartilaginous, of a substance like our mustela, and exquisite food: they are formed with regular vertebræ, and small bones all over the body divided into equal parts; are first darkish, and then grey; their scales make a beautiful appearance. Whether this animal is, in its perfect state, a species of frog with a tail, or a kind of water-lizard, Mr. Edwards does not pretend to determine, but observes, that when its size is considered, if it should be deemed a tadpole at first produced from spawn and in its progress towards a frog, such an animal, when full grown, if it bears the same proportion to its tadpole as those in Europe do, must be of enormous size; for our full-grown frogs exceed the tadpoles at least 50 times.

FRONT *of a battalion*, among military men, is the first rank, or file-leaders. It is likewise called the face or head of the battalion.

FRONTAL, or FRONTLET, or BROWBAND, is used in speaking of the Jewish ceremonies. It consists of four several pieces of vellum, on each whereof is written some text of scripture: they are all laid on a piece of calf's leather, with thongs to tie it by.

The Jews apply the leather with the velum on their foreheads in the synagogue, and tie it round the head with the thongs.

FRONTAL MUSCLES. See ANATOMY.

FRONTIS os, in anatomy, called also os coronale, the bone of the forehead. See ANATOMY.

FROST. See COLD and FREEZING.

FROTH-SPIT, or CUCKOW-SPIT, a name given to a white froth or spume, very common in the spring. It forms the nidus of a species of cicada.

FRUCTIFICATION. See BOTANY.

FRUIT. Every person who shall bark any fruit-tree, shall forfeit to the party grieved treble damages by action at the common law, and also 10*l.* to the king. 37 H. VIII. c. 6.

Every person who shall rob any orchard or garden, or dig or pull up any fruit-trees, with intent to take the same away (the same not being felony by the laws of England), shall, on conviction before one justice, give to the party such satisfaction for damages as such justices shall appoint; and in default of payment to be whipped. 43 Eliz. c. 7.

And with respect to what shall be deemed felony by the laws of England, the distinction seems to be, that if they are any way annexed to the freehold, as trees growing, or apples growing upon the trees, then the taking and carrying them away is not felony but trespass only, for a man cannot steal part of a freehold; but if they are severed from the freehold, as wood cut or apples gathered from the trees, then the taking of them is not a trespass only, but felony. Id.

Fine and imprisonment may be inflicted on persons destroying fruit-trees. 1 Geo. I. c. 48.

Robbing orchards or gardens of fruit growing therein, may be punished by fine, whipping, &c.

FRUIT-TREES. See GARDENING.

FRUMENTARII, a kind of soldiers or archers, under the western empire. The first time we read of these officers is in the time of the emperor Adrian, who made use of them to inform himself of whatever passed. They did not make any particular corps distinct from the rest of the forces, but there was a certain number of them in each legion. It is supposed that they were at first a number of young persons disposed by Augustus, throughout the provinces, particularly on all the grand roads, to acquaint the emperor, with all expedition, of every thing that happened.

FRUMENTATION, in Roman antiquity, a largess of corn bestowed on the people. This practice of giving corn to the people was very ancient among the Romans, and frequently used to sooth the turbulent humour of the populace. At first the number of those to whom this largess was given was indeterminate, till Augustus fixed it at two hundred thousand.

FRUSTUM, in mathematics, a part of some solid body separated from the rest.

The frustum of a cone is the part that remains, when the top is cut off by a plane parallell to the base, and is otherwise called a truncated cone: for finding the surface and solidity of which, see GEOMETRY and MENSURATION.

The frustum of a globe or sphere is any part of it cut off by a plane, the solid contents of which may be found by this rule. To three times the square of the semidiameter of the base add the square of its height; then multiplying that sum by the height, and this product multiplied by .5236, gives the solidity of the frustum.

A frustum or portion of any solid, generated by the revolution of any conic section upon its axis, and terminated by any two parallel planes, may be thus compared to a cylinder of the same altitude, and whose base is equal to the middle section of the frustum made by a parallel plane. 1. The difference between such frustum and cylinder is always the same in different parts of the same or of similar solids; when the inclination of the planes to the axis, and the altitude of the frustum are given. 2. In the parabolic conoid, this difference vanishes; the frustum being always equal to a cylinder of the same height, upon the section of the conoid that bisects the altitude of the frustum, and is parallel to its basis. 3. In the sphere, the friction is always less than the cylinder by one fourth part of a right-angled cone of the same height with the frustum, or, by one half of a sphere, of a diameter equal to that height: and this difference is always the same in all spheres whatever, when this altitude of the frustum is given. 4. In the cone the frustum always exceeds the cylinder by one fourth part of the

content of a similar cone, that has the same height with the frustum.

FUCHSIA, a genus of plants of the octandria monogynia class and order. The calyx is one-leafed, coloured, bearing; the corolla very large; petals four, small. Berry inferior, four-celled, many seeds. There are five species, of which the fuchsia coccinea is very beautiful, and is now a common plant, though only introduced in 1788 from Chili. It will live in the open ground, though the stem will then die off annually. In the greenhouse it is a shrub, as are all the other species.

FUCUS, a name given by the ancients to certain dyes and paints. By this name they called a purple sea-plant used by them to dye woollen and linen cloths of that colour. The dye was very beautiful, but not lasting; for it soon began to change, and in time went wholly off. This is the account Theophrastus gives of it.

The women of those times also used something called fucus to stain their cheeks red; and many have supposed, from the same word expressing both, that the same substance was used on both occasions. But this, on a strict inquiry, proves not to be the case. The Greeks called every thing fucus that would stain or paint the flesh. But this peculiar substance, used by the women to paint their cheeks, was distinguished from the others by the name of rizion among the more correct writers, and was indeed a root brought from Syria into Greece. The Latins, in imitation of the Greek name, called this root radicula; and Pliny very erroneously confounds the plant with the radix lunaria, or struthion of the Greeks.

The word fucus was in these times become such an universal name for paint, that the Greeks and Romans had a fucus mellicus, which was the cerus used for painting the neck and arms white; after which they used the purpurissum, or red fucus of the rizium, to give the colour to the cheeks. In aftertimes they also used a peculiar fucus or paint, for the purpose, prepared of the cretal argentaria or silverchalk, and some of the rich purple dyes that were in use at that time: and this seems to have been very little different from our rosepink, a colour commonly sold at the colour-shops.

Fucus, in the Linnæan system of botany, is a genus of the order of algæ, belonging to the cryptogamia class of plants. The most remarkable species are,

1. The serrantus, serrated fucus, or sea-wrack. This is frequent at all seasons of the year upon the rocks at low-water-mark, but produces its seeds in July and August. It consists of a flat, radical, and dichotomous leaf, about two feet long; the branches half an inch wide, serrated on the edges with dents of unequal size, and at unequal distances, having a flat stalk or rib divided like the leaf, and running in the middle of it through all its various ramifications. A small species of coralline, called by Linnæus certularia pumila, frequently creeps along the leaf. All the species of fucus afford a quantity of impure alkaline salts; but this much less than some others, eight ounces of the ashes yielding only three of fixed salt. The Dutch cover their crabs and lobsters with this fucus, to keep them alive and moist, and prefer it to any other, as being destitute of those mucous vesicles with which some of the rest abound, and which would sooner ferment and become putrid.

2. The vesiculosus, bladder fucus, common sea-wrack, or sea-ware. It grows in great abundance on the sea-rocks about low-water-mark, producing its fructifications in July and August. It has the same habit, colour, and substance as the foregoing, but differs from it in the following respects: the edges of the leaf have no serratures, but are quite entire. In the disc or surface are immersed hollow, spherical, or oval air-bladders, hairy within, growing generally in pairs, but often single in the angles of the branches, which are most probably air-bladders destined to buoy up the plant in the water. Lastly, on the summits or extreme segments of the leaves appear tumid vesicles about three quarters of an inch long, sometimes oval and in pairs, sometimes single and bifid, with a clear viscid mucus interspersed with downy hairs. This species is an excellent manure for land; for which purpose it is often applied in the maritime parts of Scotland and other countries. In the islands of Jura and Skye it frequently serves as a winter food for cattle, which regularly come down to the shores at the recess of the tides to seek for it. And sometimes even the stags have been observed, after a storm, to descend from the mountains to the sea-sides to feed upon this plant.

Linnæus informs us, that the inhabitants of Gothland in Sweden boil this fucus in water, and, mixing with it a little coarse meal or flour, feed their hogs with it; for which reason they call the plant swinetang. And in Scania, he says, the poor people cover their cottages with it, and sometimes use it for fuel. In Jura, and some other of the Hebrides, the inhabitants dry their cheeses without salt, by covering them with the ashes of this plant, which abounds with such a quantity of salts, that from five ounces of the ashes may be procured two ounces and a half of fixed alkaline salts, that is, half to their whole weight. But the most beneficial use to which the fucus vesiculosus is applied, in the way of economy, is in making pot-ash or kelp, a work much practised in the Western Isles. There is great difference in the goodness and price of this commodity, and much care and skill required in properly making it. That is esteemed the best which is hardest, finest grained, and free from sand or earth. The price of kelp in Jura is 3*l.* 10*s.* per ton, and about 40 or 50 tons are exported annually from that island. So great a value is set upon this fucus by the inhabitants of that place, that they have sometimes thought it worth their while to roll fragments of rocks and huge stones into the sea, in order to invite the growth of it.

Its virtues in the medical way have been much celebrated by Dr. Russel, in his Dissertation concerning the use of Sea-water in the Diseases of the Glands. He found the saponaceous liquor or mucus in the vesicles of this plant to be an excellent resolvent, extremely serviceable in dispersing all scorbutic and scrophulous swellings of the glands. He recommends the patient to rub the tumour with these vesicles bruised in his hand, till the mucus has thoroughly penetrated the part, and afterwards to wash with sea water. Or otherwise, to gather two pounds of the tumid vesicles, in the month of July, when they are full of mucus, and infuse them in a quart of sea water, in a glass vessel, for the space of 15 days, when the liquor will have acquired nearly the consistence of honey. Then strain it off through a linen cloth,

and rub this liquor with the hand, as before, three or four times a day, upon any hard or scrophulous swellings, washing the parts afterwards with sea water; and nothing can be more efficacious to disperse them. Even scirrhosities, he says, in women's breasts, have been dispelled by this treatment. The same author, by calcining the plant in the open air, made a very black salt powder, which he called vegetable æthiops; a medicine much in use as a resolvent and deobstruent, and recommended also as an excellent dentrifice to correct the scorbutic laxity of the gums, and to take off the foulness of the teeth.

3. The plicatus, matted or Indian-grass fucus, grows on the sea-shores in many places both of England and Scotland. It is generally about three or four, but sometimes six, inches long. Its colour, after being exposed to the sun and air, is yellowish or auburn; its substance pellucid, tough, and horney, so as to bear a strong resemblance to what anglers call Indian-grass, that is, the tendrils issuing from the ovary of the dog-fish.

4. The palmatus, palmated or sweet fucus, commonly called dulse or dilse. This grows plentifully on the sea-coasts of Scotland and the adjoining islands. Its substance is membranaceous, thin, and pellucid; the colour red; sometimes green with a little mixture of red; its length generally about five or six inches, but varies from three inches to a foot; its manner of growth fan-shaped, or gradually dilated from the base upwards. Its divisions are extremely various. The inhabitants both of Scotland and England take pleasure in eating this plant, without expecting any medical virtues from it. The inhabitants of the Archipelago also are fond of it, as we learn from Steller. They sometimes eat it raw, but esteem it most when added to ragouts, oglios, &c. to which it gives a red colour, and, dissolving, renders them thick and gelatinous. In the isle of Skye it is sometimes used in fevers to promote a sweat, being boiled in water with the addition of a little butter. In this manner it also frequently purges. The leaves, infused in water, exhale a scent like that of dried violets.

5. The esculentus, eatable fucus, or bladder-locks, commonly called tangle in Scotland, is likewise a native of the British shores. It is commonly about four feet long, and seven or eight inches wide; but is sometimes found three yards or more in length, and a foot in width. Small specimens are not above a cubit long, and two inches broad. The substance is thin, membranaceous, and pellucid; the colour green or olive. The root consists of tough cartilaginous fibres. The stalk is about six inches long, and half an inch wide, nearly square, and pinnated in the middle between the root and origin of the leaf, with ten or a dozen pair of thick, cartilaginous, oval-obtuse, foliaceous ligaments, each about two inches long, and crowded together. The leaf is of an oval-lanceolate, or long elliptic form, simple and undivided, waved on the edges, and widely ribbed on the middle from bottom to top, the stalk running through its whole length, and standing out on both sides of the leaf. This fucus is eaten in the north both by men and cattle. Its proper season is in the month of September, when it is in the greatest perfection. The membranous part is rejected, and the stalk only is eaten. It is recommended in the disorder called pica, to strengthen the stomach and restore the appetite.

6. The saccharinus, sweet fucus, or sea-belt, is very common on the sea-coast. The substance of this is cartilaginous and leathern, and the leaf is quite ribless. By these characters it is distinguished from the preceding, to which it is nearly allied. It consists only of one simple, linear, elliptic leaf, of a tawny green colour, about five feet long, and three inches wide in its full-grown state, but varies so exceedingly as to be found from a foot to four yards in length. The ordinary length of the stalk is two inches; but it varies even to a foot. The root is composed of branched fibres, which adhere to the stones like claws. This plant is often infested with the sertularia ciliata. The inhabitants of Iceland make a kind of pottage of this fucus, boiling it in milk, and eating it with a spoon. They also soak it in fresh water, dry it in the sun, and then lay it up in wooden vessels, where in a short time it is covered with a white efflorescence of sea-salt, which has a sweet taste like sugar. This they eat with butter; but if taken in too great a quantity, the salt is apt to irritate the bowels, and bring on a purging. Their cattle feed and get fat upon this plant, both in its recent and dry state; but their flesh acquires a bad flavour. It is sometimes eaten by the common people on the coast of England, being boiled as a pot-herb.

7. The ciliatus, ciliated or ligulated fucus, is found on the shores of Iona and other places, but is not common. The colour of this is red, the substance membranous and pellucid, without rib or nerve; the ordinary height of the whole plant about four or five inches. It is variable in its appearance, according to the different stages of its growth. This fucus is eaten by the Scots and Irish promiscuously with the fucus palmatus or dilse.

8. The prolifer, or proliferous fucus, is found on the shores of the western coast, adhering to shells and stones. The colour is red; the substance membranaceous, but tough, and somewhat cartilaginous, without rib or nerve, though thicker in the middle than at the edges. The whole length of the plant is about four or five inches, the breadth of each leaf about a quarter of an inch. The growth of this fucus, when examined with attention, appears to be extremely singular and wonderful. It takes its origin either from a simple, entire, narrow, elliptic leaf, about an inch and a half long; or from a dilated forked one of the same length. Near the extremity of the elliptic leaf, or the points of the forked one (but out of the surface, and not the edge), arises one or more elliptic or forked leaves, which produce other similar ones in the same manner near the summits; and so on continually one or more leaves from near the ends of each other, in a proliferous and dichotomous order, to the top of the plant, which in the manner of its growth resembles in a good measure the cactus opuntia, or flat-leaved Indian fig. Sometimes two or three leaves or more grow out of the middle of the disc of another leaf; but this is not the common order of their growth. The fructifications are red, spherical, rough warts, less than the smallest pin's head, scattered without order on the surface of the leaves. These warts, when highly magnified, appear to be the curled rudiments of young leaves, which in due time either drop off and form new plants, or continue on and germinate upon the parent. This plant is

very much infested with the flustra pilosa, the mandrepora verrucaria, and other corallines, which make it appear as if covered with scabs.

9. The pinnatifidus, jagged fucus, or pepper-dilse, is frequent on sea-rocks which are covered by the tides both on the eastern and western coasts. It is of a yellow olive-colour, often tinged with red. The substance is cartilaginous, but yet tender and transparent; the height about two or three inches. This fucus has a hot taste in the mouth, and is therefore called pepper-dilse by the people in Scotland, who frequently eat it as a salad, in the same manner they do the fucus palmatus.

10. The plocamium, or pectinated fucus, is frequent on the sea-rocks, and in basins of water left by the recess of the tides. Its natural colour is a most beautiful bright red or purple, but is often variegated with white or yellow. Its substance is cartilaginous, but extremely thin, delicate, and transparent; its height commonly about three or four inches. The stalk is compressed, about half a line in diameter, erect, but waved in its growth, and divided almost from the base into many widely-expanded branches. These primary branches are very long, alternate, exactly like the stalk, and subdivided into alternate secondary branches, which are again frequently compounded in like manner, and these divisions decorated with subulated teeth growing in alternate rows, curiously pectinated or finely toothed on the upper side like a comb, the smallest of these teeth scarcely visible to the naked eye. The fructifications are minute spherical capsules, or smooth dark-red globules, scattered without order on the sides of the branches, generally sessile, but some few of them supported on short peduncles. This fucus, on account of its elegant colours and fine divisions, is the species most admired by the ladies who are fond of pictures and mimic landscapes composed of marine vegetables.

11. The filum, thread-fucus, or sea-laces, is found on the sea-rocks, and waving under the water like long strings, frequent on many parts of the coast. The substance of this is opaque and cartilaginous, but not difficult to be broken. The colour, when recent, a dull olive-green; when dry, fuscous or nearly black; and, when exposed for some time on the shores to the sun and air, it becomes yellow, straw-coloured, or white. It consists only of a simple, unbranched, naked, cylindrical stalk, three or four yards long, more or less, from the size of a large fiddle-string to that of a thick whip-cord; smallest at the base and summit, smooth on the outside, full of mucus within, often twisted. and always intercepted by numerous transverse diaphragms, visible when the plant is held between the eye and the light. The fructifications have not yet been discovered; but from the transverse septa in its structure, it is reasonable to suppose this plant to belong rather to the genus of conferva than that of fucus. The stalks, skinned when half dry, and twisted, acquire so considerable a degree of strength and toughness, that we are informed the Highlanders sometimes use them for the same purpose as Indian-grass.

12. The giganteus, or gigantic fucus, is a native of the Straits Le Maire, and grows on rocky ground, which in those countries is distinguished from sand or ooze by the enormous length of the sea-weeds that grow upon it. The leaves are four feet long, and some of the stalks, though not thicker than a man's thumb, are 120. Sir Joseph Banks and Dr. Solander sounded over some of them which were 84 feet long; and as they made a very acute angle with the bottom, they were thought to be at least one half longer.

FUEL. All faggots made for sale, shall contain in compass, besides the knot of the bond, 24 inches of assize; and every faggot-stick within the bond shall contain full three feet of assize, except only one stick to be but one foot long, to stop or harden the binding. 43 Eliz. c. 14.

All billets (except those made of beech) that lie exposed in the public places, where they are usually bought or sold, shall be assized and cut as directed by 9 Anne, c. 15.

FUGAM FECIT, is where it is found by inquisition that a person fled for treason or felony; as to which it is agreed, that wheresoever a person found guilty by such inquest, either as a principal or as an accessary before the fact, is found also to have fled for the same, he forfeits his goods absolutely, and the issues of his lands, till he is pardoned or acquitted.

But wherever the indictment against a man is insufficient, the finding a fugam fecit will not hurt him; and that in all cases the particulars of the goods found to be forfeited may be traversed. 2 Haw. 450.

FUGITIVE'S GOODS, are the proper goods of him that flies, which after the flight lawfully found, belong to the king or lord of the manor. 5 Co. Rep. 109. See FELON'S GOODS.

FUGUE, in music, a term derived from the Latin word fuga, a flight, and signifying a composition either vocal or instrumental, or both, in which one part leads off some determined succession of notes called the subject, which, after being answered in the fifth and eighth by the other parts, is interspersed through the movement, and distributed amid all the parts in a desultory manner, at the pleasure of the composer; sometimes accompanied by other adventitious matter, and sometimes by itself. There are distinct descriptions of fugues; the simple fugue, the double fugue, and the counter fugue. The

Simple FUGUE contains but one subject, is the least elaborate in its construction, and the easiest in its composition.

Double FUGUE, consists of two subjects, occasionally intermingled and moving together; and the

Counter FUGUE, is that fugue in which the subjects move in a direction contrary to each other. In all the different species of fugues, the parts fly, or run after each other, and hence the derivation of the general name fugue.

FULCRUM, in mechanics, the prop or support by which a lever is sustained. See MECHANICS.

FUIRENA, a genus of the triandria monogynia class and order. The ament is imbricate; calyx none; corolla with three petal-shaped orbicular glumes, ending in a tendril. There is one species, a grass of Surinam.

FULGORA, or lantern-fly, an insect belonging to the hemiptera order. The generic character is: head produced into an inflated hollow front; antennæ beneath the eyes, of two joints, the exterior larger and globose; snout inflected; feet formed for walking.

The fulgora lanternaria, or Peruvian lantern-fly, is undoubtedly one of the most curious of insects. It is of a very considerable size, measuring nearly three inches and a half from the tip of the front to that of the tail, and about five inches and a half from wing's end to wing's end when expanded: the body is of a lengthened oval shape, and divided into several rings or segments; the head is nearly equal to the length of the rest of the animal, and is oval, inflated, and bent slightly upwards; the ground-colour is an elegant yellow, with a strong tinge of green in some parts, and marked with numerous bright red-brown variegations in the form of stripes and spots; the wings are very large, of a yellow colour, most elegantly varied with brown undulations and spots, and the lower pair are decorated by a very large eye-shaped spot on the middle of each, the iris or border of the spot being red, and the centre half red and half semitransparent white; the head or lantern is pale yellow, with longitudinal red stripes. This beautiful insect is a native of Surinam and many other parts of South America, and during the night diffuses so strong a phosphoric splendor from its head or lantern, that it may be employed for the purpose of a candle or torch; and it is said that three or four of the insects, tied to the top of a stick, are frequently used by travellers for that purpose. The celebrated madam Merian, in her work on the insects of Surinam, gives a very agreeable account of the surprise into which she was thrown by the first view of the flashes of light proceeding from these insects. "The Indians once brought me," says she, "before I knew that they shone by night, a number of these lantern-flies, which I shut up in a large wooden box. In the night they made such a noise that I awoke in a fright, and ordered a light to be brought, not knowing whence the noise proceeded. As we found that it came from the box, we opened it, but were still much more alarmed, and let it fall to the ground in a fright, at seeing a flame of fire come out of it; and as many animals as came out, so many flames of fire appeared. When we found this to be the case, we recovered from our fright, and again collected the insects, highly admiring their splendid appearance."

Dr. Darwin, in a note to some lines relative to luminous insects, in his beautiful poem the Loves of the Plants, makes madam Merian affirm, that she drew and finished her figure of the insect by its own light. On examination, however, we cannot find the least authority for this declaration on the part of madam Merian, who relates only what is above stated, with the observation that the light of one of the insects is sufficient to read a common newspaper by. It may be proper to add, that this celebrated lady falls into a mistake in supposing that a species of cicada, which she represents on the same plate with the lantern-fly, was its larva; and that it gradually was transformed into the fulgora. This information indeed she merely gives as the popular report, but at the same time takes the liberty of representing the insect in its supposed half-complete state, with the head of the fulgora, and the wings and body of the cicada. See Plate LX. Nat. Hist. fig. 211.

2. The fulgora candelaria is a much smaller species than the preceding, and is a native of China. It measures nearly two inches in length, and two inches and a half in breadth, with the wings expanded: the body is oval, and the head produced into a long horn-shaped process; the colours are very elegant, the head and horn being of a fine reddish brown or purple, and covered with numerous white specks of a mealy appearance; the thorax is of a deep or orange-yellow, and the body black above, but deep yellow beneath; the wings are oval, the upper pair blackish, with very numerous and close-set green reticulations, dividing the whole surface into innumerable squares or marks, and are farther decorated by several yellow bars and spots; the under wings are orange coloured, with broad black tips.

3. Fulgora diadema is an Indian species, and is distinguished by having a long, spiny, or muricated front, with a triple division at the tip; its colour is brown, with red and yellow variegations; it seems to have been first described and figured in the work of Seba: in size it is nearly similar to that of the preceding species.

FULICA, the *gallinule* and *coot*, in ornithology, a genus of birds of the order of grallæ. It has a convex bill, with the upper mandible fornicated over the lower at the edge; the lower mandible is gibbous behind the tip. The forehead is bald, and the feet have four toes, subpinnated. There are 25 species, 18 of which belong to the gallinule division, distinguished by having the toes furnished with broad scalloped membranes, and seven comprehend the coots which have the toes divided to their origin. The following species are among the most distinguished:

1. The chloropus, or common gallinule, is in length about 14 inches, and has a bald forehead and broad flat toes. It gets its food on grassy banks, and borders near fresh waters, and in the very waters if they are weedy. It builds upon low trees and shrubs by the water-side, breeding twice or thrice in a summer, and, when the young are grown up, drives them away to shift for themselves. This bird strikes with its bill like a hen, and in the spring has a shrill call. In flying, it hangs down its legs; in running, it often flirts up its tail, and shows the white feathers. We may observe, that the bottoms of its toes are so very flat and broad that it seems to be the bird which connects the cloven-footed aquatics with the next tribe, viz. fin-toed. It is pretty common on the continent, though in some parts more scarce than in others. It is also an inhabitant of America, from New York to Carolina, and is recorded as a native of Jamaica and other islands in the West Indies. It is said to feed on plants and small fish, and the flesh is for the most part pretty good. See Plate LX. Nat. Hist. fig. 213.

2. The porphyrio, or purple gallinule, is about the size of a domestic fowl, or 17 inches in length. It is more or less common in all the warmer parts of the globe. On the coasts of Barbary they abound, as well as in some of the islands of the Mediterranean. In Sicily they are bred in plenty, and kept for their beauty; but whether indigenous there, is uncertain. It is frequently met with in various parts of the south of Russia and the western parts of Siberia, among reedy places: in the neighbourhood of the Caspian Sea it is not uncommon; but in the cultivated rice grounds of Ghilar in Persia, it is in great plenty and high plumage. The female makes her nest among the reeds in the middle of March; lays three or four eggs, and sits from three to four weeks. It will feed on many things, such as fruit, roots of plants, and grain; but will

eat fish with avidity, dipping them into the water before it swallows them. It will frequently stand on one leg, and lift the food to its mouth with the other like a parrot. A pair of these kept in an aviary in France made a nest of small sticks mixed with a quantity of straw, and laid six white eggs, perfectly round; but the hen was careless of them, and they came to nothing. The flesh is said to be exquisite in flavour.

3. The atra or common coot, has a bald forehead, a black body, and lobated toes, and is about fifteen inches in length. They frequent lakes and still rivers; making their nests among the rushes, with grass, reeds, &c. floating on the water, so as to rise and fall with it. They lay five or six large eggs, of a dirty whitish hue, sprinkled over with minute deep rust-coloured spots; and it is said that sometimes they will lay 14 or more eggs. The young, when just hatched, are very deformed, and the head mixed with a red coarse down. In winter they often repair to the sea; and the channel near Southampton is sometimes observed almost covered with them. They are often brought to that market, where they are exposed to sale without their feathers, and scalded like pigs. This species is not so numerous as might be expected; for we find that vast numbers fall a prey while young to the buzzards, which frequent the marshes. Their food is small fish and water-insects; but they will sometimes eat the roots of the bulrush, and with it feed the young: they are said likewise to eat grain. This species is supposed to extend throughout the old continent, and perhaps the new also.

4. The aterrima, or greater coot, is of a larger size than the last, and its plumage is blacker. This species is said to be found in Lancashire and Scotland; but is more plentiful on the continent, being found in Russia and the western parts of Siberia very common. See Plate LX. Nat. Hist. fig. 212.

FULLER, a workman employed in the woollen manufactories to mill or scour cloths, serges, and other stuffs, in order to render them more thick, compact, and durable. See FULLING.

FULLER'S EARTH, in natural history, a species of clay, of a greyish ash-coloured brown, in all degrees from very pale to almost black, and it has generally something of a greenish cast. It is very hard and firm, of a compact texture, of a rough and somewhat dusty surface that adheres slightly to the tongue. It is very soft to the touch, not staining the hands, nor breaking easily between the fingers. It has a little harshness between the teeth, and melts freely in the mouth. Thrown into water, it makes no ebullition or hissing; but swells gradually in bulk, and falls into a fine soft powder. It makes no effervescence with nitrous acid.

A specimen from Hampshire, analysed by Bergman, contained

51.8	silica
25.0	alumina
3.3	carbonat of lime
3.7	oxyd of iron
0.7	carbonat of magnesia
15.5	moisture
100.0	

This earth is used by fullers to take grease out of their cloth before they apply soap. It is essential to fuller's earth that the particles of silica should be very fine, otherwise they would cut the cloth. Any clay possessed of this property may be considered as fuller's earth; for it is the alumina alone which acts upon the cloth, on account of its strong affinity for greasy substances.

FULLING, the art or act of cleansing, scouring, and pressing cloths, stuffs, and stockings, to render them stronger, closer, and firmer; called also milling. The fulling of cloths and other stuffs is performed by a kind of water-mill, thence called fulling or scouring-mill. These mills, except in what relates to the mill-stones and hopper, are much the same with corn-mills: and there are even some which serve indifferently for either use; corn being ground, and cloths fulled, by the motion of the same wheel. Whence in some places, particularly in France, the fullers are called millers; as grinding corn and milling stuffs at the same time.

The principal parts of the fulling-mill are: the wheel, with its trundle; which gives motion to the tree or middle, whose teeth communicate it to the pestles or stampers, which are hereby raised and made to fall alternately, according as its teeth catch on or quit a kind of latch in the middle of each pestle. The pestles and troughs are of wood; each trough having at least two, sometimes three, pestles, at the discretion of the master, or according to the force of the stream of water. In these troughs are laid the cloths, stuffs, &c. intended to be fulled: then, letting the current of water fall on the wheel, the pestles are successively let fall thereon, and by their weight and velocity stamp and press the stuffs very strongly, which by this means become thickened and condensed. In the course of the operation, they sometimes make use of urine, sometimes of fuller's earth, and sometimes of soap. To prepare the stuffs to receive the first impressions of the pestle, they are usually laid in urine; then in fuller's earth and water; and, lastly, in soap dissolved in hot water. Soap alone would do very well; but this is expensive: though fuller's earth, in the way of our dressing, is scarcely inferior to it; but then it must be well cleared of all stones and grittinesses, which are apt to make holes in the stuff. As to urine, it is certainly prejudical, and ought to be entirely discarded; not so much on account of its ill smell, as of its sharpness and saltness, which qualities are apt to render the stuffs dry and harsh.

The method of fulling cloths and woollen stuffs with soap is this: A coloured cloth, of about 45 ells, is to be laid in the usual manner in the trough of a fulling-mill, without first soaking it in water, as is commonly practised in many places. To full this trough of cloth, 15 pounds of soap are required, one-half of which is to be melted in two pails of river or spring water, made as hot as the hand can well bear it. This solution is to be poured by little and little upon the cloth, in proportion as it is laid in the trough; and thus it is to be fulled for at least two hours; after which it is to be taken out and stretched. This done, the cloth is immediately returned into the same trough, without any new soap, and there fulled two hours more. Then taking it out, they wring it well, to express all the grease and filth. After the second fulling, the remainder of the foap is dissolved as in the former, and cast four different times on the cloth, re-

membering to take out the cloth every two hours to stretch it, and undo the plaits and wrinkles it has acquired in the trough. When they perceive it sufficiently fulled, and brought to the quality and thickness required, they scour it in hot water, keeping it in the trough till it is quite clean. As to white cloths, as these full more easily and in less time than coloured ones, a third part of the soap may be spared.

The fulling of stockings, caps, &c. should be performed somewhat differently, viz. either with the feet or the hands, or a kind of wooden rack, either armed with teeth of the same matter, or else horses or bullocks teeth. The ingredients made use of are, urine, green soap, white soap, and fuller's earth. But the urine also is reckoned prejudicial here. Woven stockings, &c. should be fulled with the soap alone: for those that are knit, earth may be used with the soap. Indeed it is common to full these kinds of works with the mill, after the usual manner of cloths, &c.; but that is too coarse and violent a manner, and apt to damage the work, unless it is very strong.

Plate Foundry, &c. fig. 10. is a perspective view of a fulling-mill. A is the shaft which works it by the power of horses, water, steam, &c. This shaft has four arms or lifters BD upon it, two of which are to raise the wooden beater E, and the other two are to raise the beater F. In well executed mills, the shaft is made of cast-iron, as shown in fig. 12; and then the arms BDMN have rollers at their ends. The beaters E, F, are made of hard wood, as shown in fig. 11; G is the centre on which it turns, made of wood; H is a large block of wood wedged to the bar IK, which passes through it; it has three pieces of board *abc* pegged to it. The part K of the piece IK is shod with iron at the under side, to preserve it from being worn by the lifters. Two of these beaters work in a frame, shown open in fig. 13. OPQR is a large block of wood, hewn out as in the figure; to this are fastened the curved pieces ST, in which there is left two openings *de*, through which the parts K of the beaters, fig. 11. pass, and the centres lay in small holes *fghi:* when the beaters are in, as shown in fig. 10. the outside of the head H move as close to the curves ST as possible without touching, when they are in motion. The block is boarded up on both sides, as shown in fig. 10.; but one side is not boarded so high as the other, and has a moveable board *lm*, which fits into a groove for the convenience of putting in and taking out the cloth. The operation is as follows: The board *lm* is removed, and the cloth put in so as to lay between the heads H of the beaters, and the curve part XY, fig. 13.; the beaters are then set to work, and the lifters first take up one beater, and as soon as it lets that fall, it begins to take up the other: this motion continually shoves the cloth round in the curve from Y to X; and by its falling again when the beater is lifted into the place it before occupied, a fresh surface is continually exposed to the action of the boards *abc*, fig. 11. and to small streams of water supplied by a pipe *no*, fig. 10. which is full of holes: the quantity is regulated by a cock *p*. When the beaters are to be stopped, the workman takes a hankspike and lays it over the hook *q*, and when the beater is lifted to the highest, he shoves the end of the handspike under it, so as to prevent its falling down again; he then raises it enough to put an iron rod through the hole *r*: this operation is repeated to the other beater, and the iron is pushed farther in, so as to hold them both up. This machine is fixed down by two beams under the floor, between which the projector W of fig. 13. is bolted, and it is steadied by two struts, fig. 10.

FULMINATION, in chemistry. When three parts of nitre, two parts of potass, and one part of sulphur, all previously well dried, are mixed together in a warm mortar, the resulting compound is known by the name of *fulminating powder*.

If a little of this powder is put upon an iron spoon, and placed upon burning coals, or held above the flame of a candle, it gradually blackens, and at last melts. At that instant it explodes with a very violent report, and a strong impression is made upon the bottom of the spoon, as if it had been pressed down very violently. This sudden and violent combustion is occasioned by the rapid action of the sulphur on the nitre. By the application of the heat, the sulphur and potass form a sulphuret, which is combustible at a lower heat than even sulphur.

Sulphurated hydrogen gas, azotic gas, and perhaps sulphuric acid gas, are disengaged almost instantaneously. It is to the sudden action of these on the surrounding air that the report is to be ascribed. Its loudness depends upon the combustion of the whole powder at the same instant, which is secured by the previous fusion that it undergoes; whereas the grains of gunpowder burn in succession.

Fulminating gold. Dissolve pure gold in nitro-muriatic acid to saturation, and dilute the solution with three times its bulk of distilled water, and add to it gradually some pure ammonia, a yellow precipitate will be obtained, which must be repeatedly washed with distilled water, and dried on a chalk-stone or in a filter. When perfectly dry, it is called fulminating gold, and detonates by heat, as may be shown by heating a few grains of it on the point of a knife over the candle.

Fulminating silver. Dissolve fine silver in pale nitric acid, and precipitate the solution by lime water; decant the fluid, mix the precipitate with liquid ammonia, and stir it till it assumes a black colour; then decant the fluid, and leave it in the open air to dry. This product is fulminating silver, which when once obtained cannot be touched without producing a violent explosion. It is the most dangerous preparation known, for the contact of fire is not necessary to cause it to detonate. It explodes by the mere touch. Its preparation is so hazardous, that it ought not to be attempted without a mask, with strong glass eyes, upon the face. No more than a single grain ought at any time to be tried as an experiment. This was invented by M. Berthollet.

M. Chenevix has invented a fulminating silver not so dangerous as that just mentioned. It explodes only by a slight friction in contact with combustible bodies. It is thus prepared: Diffuse a quantity of alumina through water, and let a current of oxygenated muriatic acid gas pass through it for some time. Then digest some phosphate of silver on the solution of the oxygenated muriate of alumina, and evaporate it slowly. The product obtained will be a hyper-oxygenated muriate of silver, a single grain of which, in contact with two or three of sulphur, will explode violently with the slightest friction.

Fulminating mercury. The mercurial preparations which fulminate, when mixed with sulphur, and gradually exposed to a gentle heat, are well known to chemists: they were discovered, and have been fully described, by Mr. Bayen.

"MM. Brugnatelli and Van Mons have likewise produced fulminations by concussion, as well by nitrate of mercury and phosphorus as with phosphorus and most other nitrates. Cinnabar likewise is amongst the substances which, according to MM. Fourcroy and Vauquelin, detonate by concussion with oxymuriate of potash.

"M. Ameilon had, according to M. Berthollet, observed, that the precipitate obtained from nitrate of mercury, by oxalic acid, fuses with a hissing noise.

"But mercury, and most if not all its oxyds, may, by treatment with nitric acid and alcohol, be converted into a whitish crystallized powder, possessing all the inflammable properties of gunpowder, as well as many peculiar to itself.

"I was led to this discovery (says Mr. Howard, the inventor) by a late assertion, that hydrogen is the basis of the muriatic acid: it induced me to attempt to combine different substances with hydrogen and oxygen. With this view I mixed such substances with alcohol and nitric acid as might (by predisposing affinity) favour as well as attract an acid combination of the hydrogen of the one, and the oxygen of the other. The pure red oxyd of mercury appeared not unfit for this purpose; it was therefore intermixed with alcohol, and upon both nitric acid was affused. The acid did not act upon the alcohol so immediately as when these fluids are alone mixed together, but first gradually dissolved the oxide: however, after some minutes had elapsed, a smell of ether was perceptible, and a white dense smoke, much resembling that from the liquor fumans of Libavius, was emitted with ebullition. The mixture then threw down a dark-coloured precipitate, which by degrees became nearly white. This precipitate I separated by filtration; and observing it to be crystallized in smaller acicular crystals, of a saline taste, and also finding a part of the mercury volatilized in the white fumes, I must acknowledge I was not altogether without hopes that muriatic acid had been formed, and united to the mercurial oxide; I therefore, for obvious reasons, poured sulphuric acid upon the dried cystalline mass, when a violent effervescence ensued, and, to my great astonishment, an explosion took place. The singularity of this explosion induced me to repeat the process several times, and finding that I always obtained the same kind of powder, I prepared a quantity of it, and was led to make the series of experiments which I shall have the honour to relate in this paper.

"I first attempted to make the mercurial powder fulminate by concussion; and for that purpose laid about a grain of it upon a cold anvil, and struck it with a hammer, likewise cold. It detonated slightly, not being, as I suppose, struck with a flat blow; for upon using three or four grains, a very stunning disagreeable noise was produced, and the faces both of the hammer and the anvil were much indented.

"Half a grain, or a grain, if quite dry, is as much as ought to be used on such an occasion.

"The shock of an electrical battery, sent through five or six grains of the powder, produces a very similar effect. It seems, indeed, that a strong electrical shock generally acts on fulminating substances like the blow of a hammer. MM. Fourcroy and Vauquelin found this to be the case with all their mixtures of oxymuriate of potass.

"To ascertain at what temperature the mercurial powder explodes, two or three grains of it were floated on oil, in a capsule of leaf tin; the bulb of a Fahrenheit's thermometer was made just to touch the surface of the oil, which was then gradually heated till the powder exploded, as the mercury of the thermometer reached the 368th degree.

"Desirous of comparing the strength of the mercurial compound with that of gunpowder, I made the following experiment in the presence of my friend Mr. Abernethy.

"Finding that the powder could be fired by flint and steel, without a disagreeable noise, a common gunpowder proof, capable of containing eleven grains of fine gunpowder, was filled with it, and fired in the usual way: the report was sharp, but not loud. The person who held the instrument in his hand felt no recoil; but the explosion laid open the upper part of the barrel, nearly from the touch-hole to the muzzle, and struck off the hand of the register, the surface of which was evenly indented, to the depth of 0.1 of an inch, as if it had received the impression of a punch.

"The instrument used in this experiment being familiarly known, it is therefore scarcely necessary to describe it: suffice it to say, that it was of brass, mounted with a spring register, the moveable hand of which closed up the muzzle, to receive and graduate the violence of the explosion. The barrel was half an inch in caliber, and nearly half an inch thick, except where a spring of the lock impaired half its thickness.

"A gun belonging to Mr. Keir, an ingenious artist of Camden-Town, was next charged with 17 grains of the mercurial powder, and a leaden bullet. A block of wood was placed at about eight yards from the muzzle to receive the ball, and the gun was fired by a fuse. No recoil seemed to have taken place, as the barrel was not moved from its position, although it was in no ways confined. The report was feeble: the bullet, Mr. Keir conceived, from the impression made upon the wood, had been projected with about half the force it would have been by an ordinary charge, or 68 grains, of the best gunpowder. We therefore re-charged the gun with 34 grains of the mercurial powder; and as the great strength of the piece removed any apprehension of danger, Mr. Keir fired it from his shoulder, aiming at the same block of wood. The report was like the first, sharp, but not louder than might have been expected from a charge of gunpowder. Fortunately Mr. Keir was not hurt; but the gun was burst in an extraordinary manner. The breech was what is called a patent one, of the best forged iron, consisting of a chamber 0.4 of an inch thick all round, and 0.4 of an inch in caliber; it was torn open and flawed in many directions, and the gold touch-hole driven out. The barrel into which the breach was screwed was 0.5 of an inch thick; it was split by a single crack three inches long, but this did not appear to

me to be the immediate effect of the explosion. I think the screw of the breech, being suddenly enlarged, acted as a wedge upon the barrel. The ball missed the block of wood, and struck against a wall, which had already been the receptacle of so many bullets, that we could not satisfy ourselves about the impression made by the last.

"As it was pretty plain that no gun could confine a quantity of the mercurial powder sufficient to project a bullet with a greater force than an ordinary charge of gunpowder, I determined to try its comparative strength in another way. I procured two blocks of wood, very nearly of the same size and strength, and bored them with the same instrument to the same depth. The one was charged with half an ounce of the best Dartford gunpowder, and the other with half an ounce of the mercurial powder; both were alike buried in sand, and fired by a train communicating with the powders by a small touch-hole. The block containing the gunpowder was simply split into three pieces: that charged with the mercurial powder was burst in every direction, and the parts immediately contiguous to the powder were absolutely pounded, yet the whole hung together, whereas the block split by the gunpowder had its parts fairly separated. The sand surrounding the gunpowder was undoubtedly most disturbed: in short, the mercurial powder appeared to have acted with the greatest energy, but only within certain limits.

"The effects of the mercurial powder, in the last experiments, made me believe that it might be confined, during its explosion, in the centre of a hollow glass globe. Having therefore provided such a vessel, seven inches in diameter, and nearly half an inch thick, mounted with brass caps, and a stop-cock, I placed ten grains of mercurial powder on thin paper, laid on iron wire, 149th of an inch thick, across the paper, through the midst of the powder, and, closing the paper, tied it fast at both extremities with silk to the wire. As the enclosed powder was now attached to the middle of the wire, each end of which was connected with the brass caps, the packet of powder became, by this disposition, fixed in the centre of the globe. Such a charge of the electrical battery was then sent along the wire, as a preliminary experiment (with Mr. Cuthbertson's electrometer) had shown me would, by making the wire red hot, inflame the powder. The glass globe withstood the explosion, and of course retained whatever gases were generated; its interior was thinly coated with the quicksilver, in a very divided state. A bent glass tube was now screwed to the stop-cock of the brass cap, which being introduced under a glass jar standing in the mercurial bath, the stop-cock was opened. Three cubical inches of air rushed out, and a fourth was set at liberty when the apparatus was removed to the water tub. The explosion being repeated, and the air all received over water, the quantity did not vary. To avoid an error from change of temperature, the glass globe was, both before and after the explosion, immersed in water of the same temperature. It appears, therefore, that the ten grains of powder produced four cubical inches only of air.

"To continue the comparison between the mercurial powder and gunpowder, 10 grains of the best Dartford gunpowder were in a similar manner set fire to in the glass globe: it remained entire. The whole of the powder did not explode, for some complete grains were to be observed adhering to the interior surface of the glass. Little need be said of the nature of the gases generated during the combustion of the gunpowder: they must have been carbonic acid gas, sulphureous acid gas, nitrogen gas, and (according to Lavoisier) perhaps hydrogen gas. As to the quantity of these, it is obvious that it could not be ascertained; because the two first were, at least in part, speedily absorbed by the alkali of the nitre, left pure after the decomposition of its nitric acid."

The following description will give the experimental philosopher a clear idea of the instrument used in this business.

The ball or globe of glass is nearly half an inch thick, and seven inches in diameter. It has two necks, on which are cemented two brass caps, each being perforated with a female screw, to receive the male ones; through the former a small hole is drilled; the latter is furnished with a perforated stud or shank. By means of a leather collar the neck can be air-tightly closed. When a portion of the powder is to be exploded, it must be placed on a piece of paper, and a small wire laid across the paper, through the midst of the powder: the paper being then closed, it is to be tied at each end to the wire with a silken thread. One end of this wire is to be fastened to the end of the shank, and the screw inserted to half its length into the brass cap; the other end of the wire, by means of a needle, is to be drawn through the hole. The screw being now fixed in its place, and the wire drawn tight, is to be secured by pushing the irregular wooden plug into the aperture of the screw, taking care to leave a passage for the air. The stop-cock is now to be screwed on. The glass tube is bent, that it may more conveniently be introduced under the receiver of a pneumatic apparatus.

"From some of the experiments in which the gunpowder proof and the gun were burst, it might be inferred, that the astonishing force of the mercurial powder is to be attributed to the rapidity of its combustion; and a train of several inches in length being consumed in a single flash, it is evident that its combustion must be rapid. But from other experiments it is plain that this force is restrained to a narrow limit, both because the block of wood charged with the mercurial powder was more shattered than that charged with the gunpowder, whilst the sand surrounding it was least disturbed, and likewise because the glass globe withstood the explosion of ten grains of powder fixed in its centre; a charge I have twice found sufficient to destroy old pistol barrels, which were not injured by being fired when full of the best gunpowder. It also appears from the last experiment, that 10 grains of the powder produced by ignition four cubical inches only of air; and it is not to be supposed that the generation, however rapid, of four cubical inches of air, will alone account for the described force; neither can it be accounted for by the formation of a little water, which, as will hereafter be shown, happens at the same moment; the quantity formed from ten grains must be so trifling, that I cannot ascribe much force to the expansion of its vapour. The sudden vaporation of a part of the mercury seems to me a principal cause of this immense yet limited force; because its limitation may then be explained, as it is well known that

mercury easily parts with caloric, and requires a temperature of 600 degrees of Fahrenheit, to be maintained in the vaporous state. That the mercury is really converted into vapour, by ignition of the powder, may be inferred from the thin coat of divided quicksilver, which, after the explosion in the glass globe, covered its interior surface; and likewise from the quicksilver with which a tallow candle, or a piece of gold, may be evenly coated, by being held at a small distance from the inflamed powder. These facts certainly render it more than probable, although they do not demonstrate that the mercury is volatilized; because it is not unlikely that many mercurial particles are mechanically impelled against the surface of the glass, the gold, and the tallow.

"As to the force of the dilated mercury, Mr. Baumé relates a remarkable instance of it, as follows:

'Un alchymiste se présenta à Mr. Geoffroy, et l'assura qu'il avoit trouvé le moyen de fixer le mercure par une opération fort simple. Il fit construire six boites rondes en fer fort épais, qui entroient les unes dans les autres: la dernière étoit assujettie par deux cercles de fer qui se croisoient en angles droits. On avoit mis quelques livres de mercure dans la capacité de la première: on mit cet appareil dans un fourneau assez rempli de charbon pour faire rougir à blanc les boites de fer; mais, lorsque la chaleur eut pénétré suffisamment le mercure, les boites crevèrent, avec une telle explosion qu'il se fit un bruit épouvantable: des morceaux de boites furent lancés avec tant de rapidité qu'il y en eut qui passèrent au travers de deux planchers; d'autres firent sur la muraille des effects semblables a ceux des éclats de bombes.'—Chymie Expérimental et Raisonnée tom. ii. p. 393.

"Had the alchemist proposed to fix water by the same apparatus, the nest of boxes must, I suppose, have likewise been ruptured; yet it does not follow that the explosion would have been so tremendous: indeed, it is probable that it would not, for if (as Mr. Kirwan remarked to me) substances which have the greatest specific gravity have likewise the greatest attraction of cohesion, the supposition that the vapour of water, would agree with a position of sir Isaac Newton, that those particles recede from one another with the greatest force, and are most difficultly brought together, which upon contact cohere most strongly.

"Before I attempt to investigate the constituent principles of this powder, it will be proper to describe the process and manipulations which, from frequent trials, seem to be best calculated to produce it. 100 grains, or a greater proportional quantity of quicksilver, (not exceeding 500 grains), are to be dissolved, with heat, in a measured ounce and a half of nitric acid. This solution being poured cold upon two measured ounces of alcohol, previously introduced into any convenient glass vessel, a moderate heat is to be applied until an effervescence is excited. A white fume then begins to undulate on the surface of the liquor; and the powder will be gradually precipitated, upon the cessation of action and re-action. The precipitate is to be immediately collected on a filter, well washed with distilled water, and carefully dried in a heat not much exceeding that of a water bath. The immediate edulcoration of the powder is material, because it is liable to the re-action of nitric acid; and, whilst any of that acid adheres to it, it is very subject to the influence of light. Let it also be cautiously remembered, that the mercurial solution is to be poured upon the alcohol.

"I have recommended quicksilver to be used in preference to an oxide, because it seems to answer equally, and is less expensive; otherwise, not only the pure red oxide, but the red nitrous oxide, and turpeth, may be substituted; neither does it seem essential to attend to the precise specific gravity of the acid, or the alcohol. The rectified spirit of wine, and the nitrous acid of commerce, never failed, with me, to produce a fulminating mercury. It is indeed true, that the powder prepared without attention is produced in different quantities, varieties in colour, and probably in strength. From analogy, I am disposed to think the whitest is the strongest; for it is well known that the black precipitates of mercury approach the nearest to the metallic state. The variation in quantity is remarkable; the smallest quantity I ever obtained from 100 grains of quicksilver being 120 grains, and the largest 132 grains. Much depends on very minute circumstances. The greatest product seems to be obtained when a vessel is used which condenses and causes most ether to return into the mother liquor; besides which, care is to be had in applying the requisite heat, that a speedy and not a violent action be effected. 100 grains of an oxide are not so productive as 100 grains of quicksilver.

"As to the colour, it seems to incline to black when the action of the acid of the alcohol is most violent, and vice versa.

"I need not observe, that the gases which were generated during the combustion of the powder in the glass globe, were necessarily mixed with atmospheric air; the facility with which the electric fluid passes through a vacuum, made such a mixture unavoidable.

"The cubical inch of gas received over water was not readily absorbed by it; and, as it soon extinguished a taper without becoming red, or being itself inflamed, barytes water was let up to the three cubical inches received over mercury, when a carbonate of barytes was immediately precipitated.

"The residue of several explosions, after the carbonic acid had been separated, was found, by the test of nitrous gas, to contain nitrogen or azotic gas; which does not proceed from any decomposition of atmospheric air, because the powder may be made to explode under the exhausted receiver of an air-pump. It is therefore manifest that the gases generated during the cobustion of the fulminating mercury, consist of carbonic acid and nitrogen gases.

"The principal re-agents which decompose the mercurial powder are the nitric, the sulphuric, and the muriatic acids. The nitric changes the whole into nitrous gas, carbonic acid gas, acetous acid, and nitrate of mercury. I resolved it into these different principles, by distilling it pneumatically with nitric acid: this acid, upon the application of heat, soon dissolved the powder, and extricated a quantity of gas, which was found, by well-known tests, to be nitrous gas mixed with carbonic acid gas. The distillation was carried on until gas no longer came over. The liquor of the retort was then mixed with the liquor collected in the receiver, and the whole saturated with potass; which precipitated the mercury in a yellowish brown powder, nearly as it would

have done from a solution of nitrate of mercury. This precipitate was separated by a filter, and the filtrated liquor evaporated to a dry salt, which was washed with alcohol. A portion of the salt being refused by this menstruum, it was separated by filtration, and recognized, by all its properties, to be nitrate of potass. The alcoholic liquor was likewise evaporated to a dry salt, which, upon the effusion of a little concentrate sulphuric acid, emitted acetous acid, contaminated with a feeble smell of nitrous acid, owing to the solubility of a small portion of the nitre in the alcohol.

"The sulphuric acid acts upon the powder in a remarkable manner, as has already been noticed. A very concentrate acid produces an explosion nearly at the instant of contact, on account, I presume, of the sudden and copious disengagement of caloric from a portion of powder which is decomposed by the acid. An acid somewhat less concentrate likewise extricates a considerable quantity of caloric, with a good deal of gas; but, as it effects a complete decomposition, it causes no explosion. An acid diluted with an equal quantity of water, by the aid of a little heat, separates the gas so much less rapidly, that it may with safety be collected in a pneumatic apparatus. But, whatever be the density of the acid (provided no explosion be produced), there remains in the sulphuric liquor, after the separation of the gas, a white inflammable and uncrystallized powder mixed with some minute globules of quicksilver.

"To estimate the quantity, and observe the nature, of this uninflammable substance, I treated 100 grains of the fulminating mercury with sulphuric acid a little diluted. The gas being separated, I decanted off the liquor as it became clear, and freed the insoluble powder from acid by edulcoration with distilled water; after which I dried it, and found it weighed only 84 grains; consequently had lost 16 grains of its original weight. Suspecting, from the operation of the nitric acid in the former experiment, that these 84 grains (with the exception of the quicksilver globules) were oxalate of mercury, I digested them in nitrate of lime, and found my suspicion just. The mercury of the oxalate united to the nitric acid, and the oxalic acid to the lime. A new insoluble compound was formed; it weighed, when washed and dry, 48.5 grains. Carbonate of potass separated the lime, and formed oxalate of potass, capable of precipitating lime-water and muriate of lime; although it had been depurated from excess of alkali, and from carbonate acid, by a previous addition of acetous acid. That the mercury of the oxalate in the 84 grains had united to the nitric acid of the nitrate of lime was proved, by dropping muriatic acid into liquor from which the substance demonstrated to be oxalate of lime had separated; for a copious precipitation of calomel instantly ensued.

"The sulphuric liquor, decanted from the oxalate of mercury, was now added to that with which it was edulcorated, and the whole saturated with carbonate of potass. As effervescence ceased, a cloudiness and precipitation followed; and the precipitate being collected, washed and dried, weighed 3.4 grains: it appeared to be a carbonate of mercury. Upon evaporating a portion of the saturated sulphuric liquor, I found nothing but sulphate of potass; nor had it any metallic taste. There then remains, without allowing for the weight of the carbonic acid united to the 3.4 grains, a deficit from the 100 grains of mercurial powder of 12.6 grains, which I ascribe to the gas separated by the action of the sulphuric acid. To ascertain the quantity, and examine the nature of the gas so separated, I introduced into a very small tubulated retort 50 grains of the mercurial powder, and poured upon it three drachms, by measure, of sulphuric acid, with the assistance of a gentle heat. I first received it over quicksilver; the surface of which, during the operation, partially covered itself with a little black powder.

"The gas, by different trials, amounted to from 28 to 31 cubical inches: it first appeared to be nothing but carbonic acid, as it precipitated barytes water, and extinguished a taper, without being itself inflamed, or becoming red. But upon letting up to it liquid caustic ammonia, there was a residue of from 5 to 7 inches of a peculiar inflammable gas, which burnt with a greenish-blue flame. When I made use of the water-tub, I obtained from the same materials, from 25 to 27 inches only of gas, although the average quantity of the peculiar inflammable gas was likewise from 5 to 7 inches: therefore, the difference of the aggregate product, over the two fluids, must have arisen from the absorption, by the water, of a part of the carbonic acid in its nascent state. The variation of the quantity of the inflammable gas, when powder from the same parcel is used, seems to depend upon the acid being a little more or less dilute.

"With respect to the nature of the peculiar inflammable gas, it is plain to me, from the reasons I shall immediately adduce, that it is no other than the gas (in a pure state) into which the nitrous etherized gas can be resolved, by treatment with dilute sulphuric acid.

"The Dutch chemists have shown, that the nitrous etherized gas can be resolved into nitrous gas, by exposure to concentrate sulphuric acid, and that, by using a dilute instead of a concentrate acid, a gas is obtained which enlarges the flame of a burning taper, so much like the gaseous oxide of azote, that they mistook it for that substance, until they discovered that it was permanent over water, refused to detonate with hydrogen, and that the fallacious appearance was owing to a mixture of nitrous gas with inflammable gas.

"The inflammable gas separated from the powder, answers to the description of the gas which at first deceived the Dutch chemists: 1st, in being permanent over water; 2dly, refusing to detonate with hydrogen; and, 3dly, having the appearance of the gaseous oxide of azote, when mixed with nitrous gas.

"The gas separable by the same acid, from nitrous etherized gas, and from the mercurial powder, have therefore the same properties. Every chemist would thence conclude, that the nitrous etherized gas is a constituent part of the powder, and the inflammable and nitrous gas, instead of the inflammable and carbonic acid gas, had been the mixed product extricated from it by dilute sulphuric acid.

"It however appears to me, that nitrous gas was really produced by the action of the dilute sulphuric acid; and that, when produced, it united to an excess of oxygen present in the oxalate of mercury.

"To explain how this change might happen, I must premise, that my experiments have shown me that oxalate of mercury can exist in two, if not in three states.

1st. By the discovery of Mr. Ameilon, the precipitate obtained by oxalic acid, from nitrate of mercury, fuses with a hissing noise. The precipitate is an oxalate of mercury, seemingly with excess of oxygen. Mercury dissolved in sulphuric acid and precipitated by oxalic acid, and also the pure red oxide of mercury digested with oxalic acid, give oxalates in the same state. 2dly. Acetate of mercury, precipitated by oxalic acid, although a true oxalate is formed, has no kind of inflammability. I consider it as an oxalate with less oxygen than those above-mentioned. 3dly. A solution of nitrate of mercury, boiled with dulcified spirit of nitre, gives an oxalate more inflammable than any other; perhaps it contains most oxygen.

"The oxalate of mercury remaining from the powder in the sulphuric liquor is not only always in the same state as that precipitated from acetate of mercury, entirely devoid of inflammability, but contains globules of quicksilver, consequently it must have parted with even more than its excess of oxygen; and if nitrous gas was present, it would of course seize at least a portion of that oxygen. It is true, that globules of quicksilver may seem incompatible with nitrous acid; but the quantity of the one may not correspond with that of the other, or the dilution of the acid may destroy its action.

"As to the presence of the carbonic acid, it must have arisen either from a complete decomposition of a part of the oxalate; or admitting the nitrous etherized gas to be a constituent principle of the powder, from a portion of the oxygen, not taken up by the nitrous gas, being united with the carbon of the etherized gas.

"The muriatic acid, digested with the mercurial powder, dissolves a portion of it, without extricating any notable quantity of gas. The dissolution evaporated to a dry salt tastes like the corrosive sublimate; and the portion which the acid does not take up, is left in a state of an uninflammable oxalate.

"These effects all tend to establish the existence of the nitrous etherized gas, as a constituent part of the powder; and likewise corroborate the explanation I have ventured to give of the action of the sulphuric acid. Moreover, a measured ounce and a half of nitrous acid, holding 100 grains of mercury in solution and two measured ounces of alcohol, yield 90 cubical inches only of gas: whereas, without the intervention of mercury, they yield 210 inches. Upon the whole, I trust it will be thought reasonable to conclude, that the mercurial powder is composed of the nitrous etherized gas, and of oxalate of mercury with excess of oxygen. 1st. Because the nitric acid converts the mercurial powder entirely into nitrous gas, carbonic acid gas, acetous acid, and nitrate of mercury. 2dly. Because the dilute sulphuric acid resolves it into an uninflammable oxalate of mercury, and separates from it a gas resembling that into which the same acid resolves the nitrous etherized gas. 3dly. Because an uninflammable oxalate is likewise left, after the muriatic acid has converted a part of it into sublimate. 4thly. Because it cannot be formed by boiling nitrate of mercury in dulcified spirits of nitre; although a very inflammable oxalate is by this means produced. 5thly. Because the difference of the product of gas, from the same measures of alcohol and nitrous acid, with and without mercury in solution, is not trifling; and, 6thly. Because nitrogen gas was generated during its combustion in the glass globe.

"Should my conclusion be thought warranted by the reasons I have adduced, the theory of the combustion of the mercurial powder will be obvious to every chemist. The hydrogen of the oxalic acid, and of the etherized gas, is first united to the oxygen of the oxalate, forming water; the carbon is saturated with oxygen, forming carbonic acid gas; and a part, if not the whole of the nitrogen of the etherized gas, is separated in the state of nitrogen gas; both which last gases, it may be recollected, were after the explosion present in the glass globe. The mercury is revived, and, I presume, thrown into vapour; as may well be imagined, from the immense quantity of caloric extricated, by adding concentrate sulphuric acid to the mercurial powder.

"I will not venture to state with accuracy in what proportions its constituent principles are combined. The affinities I have brought into play are complicated, and the constitution of the substances I have to deal with not fully known. But to make round numbers, I will resume the statement, that 100 grains of the mercurial powder lost 16 grains of its original weight, by treatment with dilute sulphuric acid: 84 grains of the mercurial oxalate, mixed with a few minute globules of quicksilver, remained undissolved in the acid. The sulphuric liquor was saturated with carbonic of potass, and yielded 3.4 grains of carbonate of mercury. If 1.4 grains should be thought a proper allowance for the weight of carbonic acid in the 3.4 grains, I will make that deduction, and add the remaining 2 grains to the 84 grains of mercurial oxalate and quicksilver; I shall then have,

Of oxalate and mercury	86 grains.
And a deficit, to be ascribed to the nitrous etherized gas and excess of oxygen,	14
	100

"It may perhaps be proper to proceed still further, and recur to the 48.5 grains, separated by nitrate of lime from the 84 grains of mercurial oxalate and globules of quicksilver. These 48.5 grains were proved to be oxalate of lime; but they contained a minute inseparable quantity of mercury, almost in the state of quicksilver, formerly part of the 84 grains from which they were separated. Had the 48.5 grains been pure calcareous oxalate, the quantity of pure oxalic acid in them would, according to Bergmann, be 23.28 grains. Hence, by omitting the 2 grains of mercury, in the 3.4 grains of carbonate, 100 grains of the mercurial powder might have been said to contain of pure oxalic acid 23.28 grains; of mercury 62.72 grains; and of nitrous etherized gas and excess of oxygen 14 grains. But as the 48.5 grains were not pure oxalate, inasmuch as they contained the mercury they received from the 84 grains, from which they were generated by the nitrate of lime, some allowance must be made for the mercury successively intermixed with the 84 grains and the 48.5 grains. In order to make corresponding numbers, and allow for unavoidable errors, I shall estimate the quantity of that mercury to have amounted to 2 grains, which I must of course deduct from the 33.28 grains of oxalic acid. I shall then have the following statement:

That 100 grains of fulminating mercury ought to contain of pure oxalic acid,	21.28 grains.
Of mercury formerly united to the oxalic acid	60.72
Of mercury dissolved in the sulphuric liquor,	2
And of mercury left in the sulphuric liquor after the separation of the gases,	2
Total of mercury,	64.72
Of nitrous etherized gas, and excess of oxygen,	14
	100

"Since 100 grains of the powder seem to contain 64.72 grains of mercury, it will be immediately inquired, what becomes of 100 grains of quicksilver, when treated as directed, in the description of the process for preparing the fulminating mercury.

"It has been stated that 100 grains of quicksilver produce, under different circumstances, from 120 to 132 grains of mercurial powder; and, if 100 grains of this powder contain 64.72 grains, 120 grains, or 132 grains, must, by parity of reasoning, contain 78.06 grains, or 85.47 grains; therefore 13.34 grains, or 20.75 grains, more of the 100 grains are immediately accounted for; because 64.72 grains + 13.34 grains = 78.06, and 64.72 grains + 20.75 grains = 85.47 grains. The remaining deficiency of 21.94 grains, or 14.53 grains, which with the 78.06 grains, or 85.47 grains, would complete the original 100 of quicksilver, remains partly in the liquor from which the powder is separated, and is partly volatilized in the white dense fumes, which in the beginning of this paper I compared to the liquor fumans of Libavius. The mercury cannot, in either instance, be obtained in a form immediately indicative of its quantity; and a series of experiments, to ascertain the quantities in which many different substances can combine with mercury, is not my present object. After observing that the mercury left in the residuary liquor can be precipitated in a very subtile dark powder, by carbonate of potass, I shall content myself with examining the nature of the white fumes.

"It is clear that these white fumes contain mercury: they may be wholly condensed in a range of Woulfe's apparatus, charged with a solution of muriate of ammonia. When the operation is over, a white powder is seen floating with ether on the saline liquor, which, if the bottles are agitated, is entirely dissolved. After the mixture has been boiled, or for some time exposed to the atmosphere, it yields to caustic ammonia a precipitate, in all respects similar to that which is separated by caustic ammonia from corrosive sublimate.

"I would infer from these facts, that the white dense fumes consist of mercury, or perhaps oxide of mercury, united to the nitrous etherized gas; and that, when the muriate of ammonia containing them is exposed to the atmosphere, or is boiled, the gas separates from the mercury; and the excess of nitrous acid, which always comes over with nitrous ether, decomposes the ammoniacal muriate of sublimate, and forms corrosive mercurial muriate or sublimate. This theory is corroborated by comparing the quantity of gas estimated to be contained in the fulminating mercury with the quantities of gas yielded from alcohol and nitrous acid, with and without mercury in solution; not to mention that more ether, as well as more gas, is produced without the intervention of mercury; and that, according to the Dutch chemists, the product of ether is always in the inverse ratio to the product of nitrous etherized gas. Should a further proof be thought necessary to the existence of the nitrous etherized gas in the fulminating mercury, as well as in the white dense fumes, it may be added, that if a mixture of alcohol and nitrous acid holding mercury in solution be so dilute, and exposed of a temperature so low, that neither ether nor nitrous etherized gas are produced, the fulminating mercury, or the white fumes, will never be generated; for, under such circumstances, the mercury is precipitated chiefly in the state of an inflammable oxalate. Further, when we consider the different substances formed by an union of nitrous acid and alcohol, we are so far acquainted with all, except the ether and the nitrous etherized gas, as to create a presumption, that no others are capable of volatilizing mercury, at the very low temperature in which the white fumes exist, since during some minutes, they are permanent over water of 40° Fahrenheit.

"Hitherto, as much only has been said of the gas which is separated from the mercurial powder by dilute sulphuric acid, as was necessary to identify it with that into which the same acid can resolve the nitrous etherized gas: I have further to speak of its peculiarity.

"The characteristic properties of the inflammable gas seem to me to be the following: 1st. It does not diminish in volume, either with oxygen or nitrous gas. 2dly. It will not explode with oxygen by the electric shock, in a close vessel. 3dly. It burns like hydrocarbonate, but with a blueish-green flame; and, 4thly. It is permanent over water.

"It is of course either not formed, or is convertible into nitrous gas by the concentrate nitric and muriatic acids; because by those acids, no inflammable gas was extricated from the powder.

"Should this inflammable gas prove not to be hydrocarbonate, I shall be disposed to conclude that it has nitrogen for its basis; indeed, I am at this moment inclined to that opinion, because I find that Dr. Priestley, during his experiments on his dephlogistigated nitrous air, once produced a gas which seems to have resembled this inflammable gas, both in the mode of burning and in the colour of the flame.

"After the termination of the common solution of iron in spirit of nitre, he used heat, and got, says he, 'such a kind of air as I had brought nitrous air to be, by exposing it to iron, or liver of sulphur; for, on the first trial, a candle burned in it with a much enlarged flame. At another time, the application of a candle to air produced in the same manner, was attended with a real, though not a loud explosion; and immediately after this a greenish-coloured flame descended from the top to the bottom of the vessel in which the air was contained. In the next produce of air, from the same process, the flame descended blue, and very rapidly from the top to the bottom of the vessel.

"These greenish and blue-coloured flames, descending from the top to the bottom of the vessel, are precisely descriptive of the inflammable gas separated from the powder. If it can be produced with certainty by the

repetition of Dr. Priestley's experiments, or should it by any means be got pure from the nitrous etherized gas, my curiosity will excite me to make it the object of future research; otherwise, I must confess, I shall feel more disposed to prosecute other chemical subjects: for having reason to think that the density of the acid made a variation in the product of this gas, and having never found that any acid, however dense, produced an immediate explosion, I once poured 6 drachms of concentrate acid upon 50 grains of the powder. An explosion, nearly at the instant of contact, was effected: I was wounded severely, and most of my apparatus destroyed. A quantity moreover of the gas I had previously prepared, was lost by the inadvertency of a person who went into my laboratory, whilst I was confined by the consequences of this discouraging accident. But should any one be desirous of giving the gas a further examination, I again repeat, that as far as I am enabled to judge, it may with safety be prepared by pouring 3 drachms of sulphuric acid, diluted with the same quantity of water upon 50 grains of the powder, and then applying the flame of a candle until gas begins to be extricated. The only attempt I have made to decompose it, was by exposing it to copper and ammonia; which during several weeks did not effect the least alteration.

"I will now conclude (says Mr. Howard), by observing, that the fulminating mercury seems to be characterised by the following properties:

"It takes fire at the temperature of 368 Fahrenheit; explodes by friction, by flint and steel, and by being thrown into concentrate sulphuric acid. It is equally inflammable under the exhausted receiver of an air-pump, as surrounded by atmospheric air; and it detonates loudly, both by the blow of a hammer, and by a strong electrical shock.

"Notwithstanding the compositions of fulminating silver and of fulminating gold differ essentially from that of fulminating mercury, all three have similar qualities. In tremendous effects, silver undoutedly stands first, and gold perhaps the last. The effects of the mercurial powder and of gunpowder admit of little comparison. The one exerts, within certain limits, an almost inconceivable force: its agents seem to be gas and caloric, very suddenly set at liberty, and both mercury and water thrown into vapour. The other displays a more extended but inferior power: gas and caloric are, comparatively speaking, liberated by degrees; and water, according to count Rumford, is thrown into vapour.

"Hence it seems that the fulminating mercury, from the limitation of its sphere of action, can seldom, if ever, be applied to mining; and, from the immensity of its initial force, cannot be used in fire-arms, unless in cases where it becomes an object to destroy them; and where it is the practice to spike cannon, it may be of service, because I apprehend it may be used in such a manner as to burst cannon without dispersing any splinters.

"The inflammation of fulminating mercury by concussion offers nothing more novel or remarkable than the inflammation, by concussion, of many other substances. The theory of such inflammations has been long since exposed by the celebrated Mr. Berthollet, and confirmed by Messieurs Fourcroy, and Vanquelin: yet, I must confess, I am at a loss to understand why a small quantity of mercurial powder made to detonate by the hammer, or the electric shock, should produce a report so much louder than when it is inflamed by a match, or by flint and steel. It might at first be imagined, that the loudness of the report could be accounted for, by supposing the instant of the inflammation, and that of the powder's confinement between the hammer and anvil, to be precisely the same, but, when the electrical shock is sent though or over a few grains of the powder, merely laid on ivory, and a loud report in consequence, I can form no idea of what causes such a report.

"The operation by which the powder is prepared, is perhaps one of the most beautiful and surprising in chemistry; and it is not a little interesting to consider the affinities which are brought into play. The superabundant nitrous acid of the mercurial solution must first act on the alcohol, and generate ether, nitrous etherized gas, and oxalic acid. The mercury unites to the two last in their nascent state, and relinquishes fresh nitrous acid, to act upon any unaltered alcohol. The oxalic acid, a predisposing affinity seems exerted in favour of its quantity, is evidently not formed fast enough to retain all the mercury; otherwise, no white fumes during a considerable period of the operation, but fulminating mercury alone will be produced.

"Should any doubt still be entertained of the existence of the affinities which have been called predisposing or conspiring, a proof that such affinities really exist, will, I think, be afforded, by comparing the quantity of oxalic acid which can be generated from given measures of nitrous acid and alcohol, with the intervention of mercury, and the intervention of other metals. For instance, when two measured ounces of alcohol are treated with a solution of 100 grains of nickel in a measured ounce and a half of nitrous acid, little or no precipitate is produced; yet, by the addition of oxalic acid to the residuary liquor, a quantity of oxalate of nickel, after some repose, is deposited. Copper affords another illustration; 100 grains of copper dissolved in a measured ounce and a half of nitrous acid, and treated with alcohol, yielded me about 18 grains of oxalate, although cupreous oxalate was plentifully generated by dropping oxalic acid into the residuary liquor. About 21 grains of pure oxalic acid seem to be produced from the same materials, when 100 grains of mercury are interposed. Besides, according to the Dutch paper, more than once referred to, acetous acid is the principal residue after the preparation of nitrous ether. How can we explain the formation of a greater quantity of oxalic acid from the same materials, with the intervention of 100 grains of mercury, than with the intervention of 100 grains of copper, otherwise than by the notion of conspiring affinities, so analogous to what we see in other phenomena of nature?

"I have attempted, without success, to communicate fulminating properties, by means of alcohol, to gold, platina, antimony, tin, copper, iron, lead, zinc, nickel, bismuth, cobalt, arsenic, and manganese; but I have not yet sufficiently varied my experiments to enable me to speak with absolute certainty. Silver, when 20 grains of it were treated with nearly the same proportions of nitrous acid, and alcohol as 100 grains of mercury, yielded, at the end of the operation, about three grains of a grey precipitate, which fulminated with extreme

violence. Mr. Cruickshank had the goodness to repeat the experiment: he dissolved 40 grains of silver in two ounces of the strongest nitrous acid diluted with an equal quantity of water, and obtained (by means of two ounces of alcohol) 60 grains of a very white powder, which fulminated like the grey precipitate above described. It probably combines with the same principles as the mercury, and of course differs from Mr. Berthollet's fulminating silver, before alluded to. I observe, that a white precipitate is always produced in the first instance; and that it may be preserved by adding water as soon as it is formed; otherwise, when the mother liquor is abundant, it often becomes grey, and is re-dissolved."

Several trials of the mercurial powder were afterwards made at Woolwich, in conjunction with colonel Bloomfield and Mr. Cruickshank, upon heavy guns, carronades, &c. from which Mr. Howard generally infers, that any piece of ordinance might be destroyed, by employing a quantity of the mercurial powder equal in weight to one half of the service-charge of gunpowder; and, from the seventh and last experiment, we may also conclude, that it would be possible so to proportion the charge of mercurial powder to the size of different cannons, as to burst them without dispersing any splinters. But the great danger attending the use of fulminating mercury, on account of the facility with which it explodes, will probably prevent its being employed for that purpose.

"In addition to the other singular properties of the fulminating mercury (says Mr. Howard), it may be observed, that two ounces inflamed in the open air seem to produce a report much louder than when the same quantity is exploded in a gun capable of resisting its action. Mr. Cruickshank, who made some of the powder by my process, remarked that it would not inflame gunpowder. In consequence of which, we spread a mixture of coarse and fine-grained gunpowder upon a parcel of the mercurial powder; and after the inflammation of the latter, we collected most, if not all, of the grains of gunpowder. Can this extraordinary fact be explained by the rapidity of the combustion of fulminating mercury? or is it to be supposed (as gunpowder will not explode at the temperature at which mercury is thrown into vapour) that sufficient caloric is not extricated during this combustion? From the late opportunity I have had of conversing with Mr. Cruickshank, I find that he has made many accurate experiments on gunpowder; and he has permitted me to state, that the matter which remains after the explosion of gunpowder consists of potass united with a small proportion of carbonic acid, sulphate of potass, and a very small quantity of sulphuret of potass, and unconsumed charcoal. That 100 grains of good gunpowder yielded about 53 grains of this residuum, of which three are charcoal. That it is extremely deliquescent, and when exposed to the air, soon absorbs moisture sufficient to dissolve a part of the alkali; in consequence of which the charcoal becomes exposed, and the whole assumes a black or very dark colour. Mr. Cruickshank likewise informs me, that after the combustion of good gunpowder under mercury, no water is ever perceptible."

Fulmination, in the Romish canon law, a sentence of a bishop, official, or other ecclesiastic appointed by the pope, by which it is decreed, that some bull sent from the pope shall be executed.

Fulmination is also used for the denunciation, or execution of a sentence of anathema, made public with due solemnity.

FUMARIA, *fumitory*, a genus of the pentandria order, belonging to the diadelphia class of plants, and in the natural method ranking under the 24th order, corydales. The calyx is diphyllous, the corolla ringent, and there are two membranaceous filaments, each of which has three antheræ. There are a number of different species, all of them low, shrubby, and deciduous and evergreen plants, growing from two to six or seven feet high, adorned with small simple leaves, and papilionaceous flowers of different colours. The most remarkable is the officinalis or common fumitory, which grows naturally in shady cultivated grounds, and produces spikes or purplish flowers in May and June. It is very juicy, of a bitter taste, without any remarkable smell. The medical effects of this herb are, to strengthen the tone of the bowels, gently loosen the belly, and promote the urinary and other natural secretions. The old physicians recommended it in melancholic, scorbutic, and cutaneous disorders, for opening obstructions of the viscera, attenuating and promoting the evacuation of viscid juices. Frederic Hoffman had a very great opinion of it as a purifier of the blood; and assures us that in this intention scarce any plant exceeds it. Cows and sheep eat this plant; goats are not fond of; horses and swine refuse it.

FUMIGATION, in chemistry, a kind of calcination, when metals, or other hard bodies, are corroded or softened, by receiving certain fumes for that purpose.

Fumigation, in medicine and surgery, the application of fumes to particular parts of the body; as those of factitious cinnabar to venereal ulcers. See Surgery.

FUNCTION, the act of fulfilling the duties of any employment.

Function, *animal*, applied to the actions of the body, is by physicians divided into vital, animal, and natural. The vital functions are those necessary to life, and without which the individual cannot subsist; as the motion of the heart, lungs, &c. The natural functions are such as it cannot subsist any considerable time without them, as the digestion of the aliment, and its conversion into blood. Under animal functions are included the senses of touching, tasting, &c. memory, judgment, and voluntary motion, without any or all of which an animal may live, but not very comfortably.

The animal functions perform the motion of the body by the action of the muscles, and this action consists chiefly in shortening the fleshy fibres, which is called contraction, the principal agents of which are the arteries and nerves distributed in the fleshy fibres.

In short, all parts of the body have their own functions, or actions peculiar to themselves. Life consists in the exercise of these functions, and health in the free and ready exertion of them. See Physiology, Digestion, Respiration, Perspiration.

FUND, in anatomy, signifies the bottom of any cavity in the body: thus, the fund of the eye is that part possessed by the choroides and retina.

FUNDS, *public*. When the practice was first adopted of borrowing money of individuals, for defraying the extraordinary expenses of the state, the produce of some

particular tax was generally appropriated as the fund out of which the principal and interest of the debt was to be discharged. The possession of the acknowledgment given by government for the money advanced, establishing a right to receive the payments from the fund originally agreed upon, the sale of these securities was considered as a sale of the claim upon the fund, and as the acknowledgments given were of different kinds, the general appellation of the provision on which they rested was found more convenient for purposes of business: thus the sale and purchase of the government securities was commonly called the sale or purchase of the public funds, till at length the expression has so far varied from its original signification, that instead of meaning the revenue out of which public debts or the interest of them is payable, it denominates the capital of such debts, in which sense it is generally used. Variations in the saleable value of the public funds at first were caused chiefly by political events, which were supposed to affect either the authority of those by whom the debts were contracted, or the means of paying them; but since their great increase has induced many persons to make buying and selling shares therein a regular trade, the fluctuations of the current price in general depends principally on the proportion of buyers to sellers, and on the schemes and combinations in which they engage in support of their respective speculations.

The chief part of the public funds consists of perpetual annuities, or those debts on which a stipulated rate of interest is to continue to be paid, unless the principal should be redeemed; the other parts consist of annuities for a certain number of years, and life annuities. The perpetual annuities are distinguished by different titles, according to the rate of interest they pay or the time and purpose of their creation; and when government, by a loan, contracts an additional debt, bearing a certain fixed interest, it is usual to add the capital thus created to the amount of that part of the public debt which bears the same interest and denomination, and to add the produce of the taxes imposed for payment of the interest of such new debt to the fund provided for paying the interest of the former capital, thus consolidating the old and new debts, and making the interest payable out of the general produce of the same fund; hence we have 3 per cent. 4 per cent. and 5 per cent. consolidated annuities. The reduced 3 per cent. annuities take their title from having originally consisted of sums which had been borrowed at higher rates of interest, and reduced at different periods to 3 per cent. The navy 5 per cents are so called from having been created by funding navy and victualling bills. The long annuities have been granted at different periods, and for different terms, but all extended to 5th January 1806. The short annuities expired 5th January 1808. The imperial 3 per cent. annuities, and annuities for 25 years, arose from loans to the emperor of Germany, the dividends on which are guaranteed by the government of this country.

The public funds were formerly all payable and transferrable at the exchequer; but, except a few annuities, of which the term is nearly expired, and some life and tontine annuities, they are all now payable at the Bank or South Sea house.

The funds transferrable at the Bank of England are at present the following, viz.

	Transfer days	Dividends due.
5 per cent. navy ann.	Monday, Wednesday, and Friday	Jan. 5. and July 5.
3 per cent. consols	Tuesday, Wednesday, Thurs. and Frid.	
3 per cent. 1726	Tuesday and Thursday	
3 per cent. deferred	Monday, Wednesday, and Friday	April 5 and Oct. 10.
Bank-stock	Tuesday, Thursday, and Friday	
5 per cent. 1797 and 1802	Tuesday, Thursday, and Friday	
4 per cent. consols	Tuesday, Thursday, and Saturday	
3 per cent. reduced	Tuesday, Wednesday, Thurs. and Frid.	
Long annuities	Monday, Wednesday, and Saturday	
Short annuities	Monday, Wednesday, and Saturday	
3 per cent. imperial ann.	Monday, Wednesday, and Friday	May 1 and Nov. 1.
Imperial annuity, 25 years	Tuesday, Thursday, and Saturday	
Irish 5 per cent.	Tuesday, Thursday, and Saturday	Mar. 25 & Sept. 25.
Irish annuities	Tuesday, Thursday, and Saturday	
Transferable at the South-Sea house.		
South-Sea stock	Monday, Wednesday, and Friday	Jan. 5. and July 5.
3 per cent. new S. S. ann.	Tuesday, Thursday, and Saturday	
3 per cent. 1751	Tuesday and Thursday	
3 per cent. old S. S. ann.	Monday, Wednesday, and Friday	April 5 & Oct. 10.

The dividend payable to the proprietors of bank-stock is 7 per cent.; on South-Sea stock $3\frac{1}{2}$ per cent. Indian stock can no longer be classed among the public funds, as the debt due from the public to the company was cancelled on the last renewal of their charter, the dividend payable to the proprietors is $10\frac{1}{2}$ per cent. Transfers of stock in any of the government funds, if made on the appointed transfer days, are free from any expense to the parties, but the same stock cannot be transferred twice on the same day. The person who transfers property in the funds, or his broker, must be known to the witnessing clerk, or some person known must be produced to vouch for his being the identical person he is represented to be. The seller's receipt should be kept by the buyer, as a voucher for the transfer, till one dividend has been received.

Dividends on bank-stock, South-sea stock, and India-stock, after acceptance, are payable to a written order; but those respecting India-stock are payable the day after they become due; but the dividends on the stock of other companies, and on the government funds, are not payable till about a week after. The space between the shutting and opening the books of any stock is usually

about six weeks. At the time of shutting, the dividends due are carried to a separate account, and cannot be transferred with the stock of a proprietor, the warrants being filled up in the name the stock stands in when the books shut, and of course are payable only to him or his attorney. All letters of attorney, to sell or accept stock or to receive dividends, should be taken out at the respective offices, in order that the description may exactly accord with that in the bank-books, and there must be a separate letter of attorney for each different stock. Letters to sell must be deposited in the proper office prior to sale, as must also probates of wills, till registered. Acting personally, after granting a letter of attorney, revokes the power of the letter. Any one trustee after the acceptance of the whole trust, may receive dividends; and, upon the death of any of the trustees being proved by producing their wills or a certificate of burial, the survivor may transfer the stock.

Persons having occasion to invest money in the public funds generally employ a broker, to whom the party must give his name, place of abode, and usual addition, with the sum intended to be purchased. The broker soon finds a seller of the sum wanted; and having agreed upon the rate per cent. to be paid, according to the current price of the day, the particulars of the bargain are delivered to a clerk in the office in the Bank in which the description of stock intended to be purchased is transferrable. The clerk on finding that such stock stands in the seller's name, fills up a form of transfer, which is signed by the seller, conveying all his right and title to the stock to the purchaser, his heirs or assigns. A form of acceptance is then signed by the purchaser, and the seller having given him a receipt expressing the consideration paid, which is witnessed by the bank-clerk, the business is concluded.

As the prices of the several funds are continually fluctuating, and there is frequently a considerable difference in the interest produced by investing money in different funds, the following table of the prices which each fund should be at to produce an equal interest, will be found very useful to persons investing their money in these securities.

TABLE

Shewing the Comparative Value per Cent. of the several Public Funds, and the Annual Interest produced by L.100 invested at different Prices.

3 per Cents	4 per Cents.	5 per Cents.	Bank Stock, 7 per c.	Ind. St. 10½ per Cent.	Annual Interest.

Table of all the intermediate prices, and for comparing the value of the terminable Annuities with the other Funds, are given in Fairman's Guide to Purchasers in the Public Funds. Some useful information respecting the Funds, and the mode of transacting business at the Bank and Stock Exchange, will also be found in Mortimer's Every Man his Own Broker.

FUNDAMENTAL NOTE, in music, the principal note in a song, or composition, to which all the rest are in some measure adapted. and by which they are swayed: it is otherwise called the key to the song.

FUNERAL EXPENSES, are allowed previous to all other debts and charges; but if the executor or administrator be extravagant, it is a species of devastation or waste of the substance of the deceased, and shall only be prejudical to himself and not to the creditors or legatees of the deceased. 2 Bl. 508.

But in strictness, no funeral expenses are allowed against a creditor, except for the shroud, coffin, ringing the bell, parson, clerk, grave-digger, and bearers' fees, but not for pall or ornaments. 1 Salk 190.

And in general it is said, that no more than 40*s.* in the whole for funeral expenses, shall be allowed against creditors. 3 Atk. 249.

FUNGI, from σφογγος, fungus, the name of the 4th order of the 24th class of vegetables, in the Linnæan system; comprehending all those which are of the mushroon kind, and which, in Tournefort, constitute the 2d, 3d, 4th, 5th, 6th, 7th, and 8th genera of the first section in the class xvii. This order in Linnæus contains 10 genera. See AGARICUS, BOLETUS, CLAVARIA, LYCOPERDON, &c.

The ancients called fungi children of the earth, meaning, no doubt, to indicate the obscurity of their origin.

The moderns have likewise been at a loss in what rank to place them; some referring them to the animal, some to the vegetable, and others to the mineral kingdom. Messrs. Wilck and Munchausen have not scrupled to rank these bodies in the number of animal productions; because when fragments of them or their seeds were macerated in water, these gentlemen perceived a quantity of animalcules discharged, which they supposed capable of being changed into the same substance. It was the ancient opinion that beef could produce bees; but it was reserved for Messrs. Wilck and Munchausen to suppose, that bees could produce beef. Wilck asserts, that fungi consist of innumerable cavities, each inhabited by a polype; and he ascribes the formation of them to their inhabitants, in the same way as it has been said that the coral, the lichen, and the mucor were formed. Hedwig has lately shown how ill founded this opinion is with respect to the lichen; and M. Durande has demonstrated its falsity with regard to the corallines. "Indeed (says M. Bonnet, talking of the animality of fungi) nothing but the rage for paradox could induce any one to publish such a fable; and I regret that posterity will be able to reproach our times with it. Observation and experiment should enable us to overcome the prejudices of modern philosophy, now that those of the ancient have disappeared and are forgotten."

It cannot be denied that the mushroom is one of the most perishable of all plants, and it is therefore the most favourable for the generation of insects. Considering the quickness of its growth, it must be furnished with a power of copious absorption; the extremities of its vessels must be more dilated than in other plants. Its root seems, in many cases, to be merely intended for its support; for some species grow upon stones or moveable sand, from which it is impossible that they can draw much nourishment. We must therefore suppose, that it is chiefly by the stalk that they absorb. These stalks grow in a moist and tainted air, in which float multitudes of eggs, so small, that the very insects they produce are with difficulty seen by the microscope. These eggs may be compared to the particles of the byssus, 100.000 of which, as M. Gleditsch says, are not equal to the fourth of a grain. May we not suppose that a quantity of such eggs are absorbed by the vessels of the fungus, that they remain there, without any change, till the plant begins to decay?

FUNGITÆ, in natural history, a kind of fossile coral, of a conic figure, though sometimes flatted and striated longitudinally.

FUNGUS, in surgery, denotes any spongy excrescence. See SURGERY.

FURCA and FOSSA, in our old customs, the power of gallows and pit, or a jurisdiction of punishing felons, viz. the men by hanging, and the women by drowning.

FURCA, in antiquity, a piece of timber resembling a fork, used by the Romans as an instrument of punishment, which was of three kinds: the first only ignominious, when a master, for small offences, forced his servant to carry a furca on his shoulders about the city. The second was penal, when the party was led about the circus, or other place, with the furca about his neck, and whipped all the way. The third was capital, when the malefactor, having his head fastened to the furca, was whipped to death.

FURCAM, ET FLAGELLUM, the meanest of all servile tenures, the bondman being at the lord's disposal for life and limb.

FURCHE', in heraldry, a cross forked at the ends.

FURIA, in zoology, a genus of insects belonging to the order of vermes zoophyta. There is but one species, viz. the infernalis. This has a linear smooth body ciliated on each side, with reflexed feelers pressed to its body. In Finland, Bothnia, and the northern provinces of Sweden, it is not unfrequently that people are seized with a pungent pain, confined to a point, in the hand or other exposed part of the body, which presently increases to a most excruciating degree and even sometimes proves suddenly fatal. This disorder, caused by the insect dropping out of the air, and in a moment burying itself in the flesh, is relieved by a poultice of curds or cheese.

FURLING, in the sea-language, signifies the wrapping up and binding any sail close to the yard; which is done by hauling upon the clew-lines, bunt-lines, &c. which wraps the sail close together, and being bound fast to the yard, the sail is furled.

FURLONG, a long measure, equal to $\frac{1}{8}$ of a mile, or forty poles. It is also used, in some law-books, for the eighth part of an acre.

FURLOUGH, in the military language, a licence granted by an officer to a soldier, to be absent for some time from his duty.

FURNACE, an utensil to raise and maintain a vehement fire in, whether of coal or wood.

In order to apply fire, to manage and to direct it where it is to act, furnaces are convenient, and they are the most necessary and indispensable instruments to chemists. The materials of which they are constructed ought to be sufficiently proof against that degree of heat, which they are intended to be exposed to. Commonly they are built of bricks, made of sand and clay, or of cast-iron, or of iron plates, which, the better to be defended against the fire, are coated (in the inside) to the thickness of an inch with Windsor loam. According to Lewis, various kinds of fireproof furnaces, for small experiments, may be prepared from black-lead crucibles.

The burning of the fuel is kept up in the furnace either by a natural current of air, which is caused by the fire itself, and such a furnace is called an air wind-furnace; or it is done by compressed air, conveyed to the furnace by a large bellows, as in blast-furnaces.

Every wind furnace consists of two essential parts: the fire-place hearth, or that where the material destined for the fuel is placed; and the ash-pit, that receives the ashes of the consumed fuel, admits the air through its aperture (the ash-hole), and is separated from the hearth by the grate.

If the bodies to be examined are not immediately placed upon the fire, but either on iron bars, or in vessels to be heated by the fire, then a third space, the laboratory, is formed in the wind-furnace. If by the laboratory the fire-place is thoroughly closed, it must be provided with some vent-holes, or registers, to allow access of air.

Such wind-furnaces as are closed by a vaulted cover, and have either at top or on the inside, a narrow vent-

pipe. or chimney, are called reverberatory furnaces, cuppelling furnaces. Sometimes the fire-place is a part of a seprate furnace, from which, however, by the draught of air, the flame of the fuel is forced over, striking upon the hearth of the cuppelling-furnace, which then is to be considered as the laboratory.

The current of air in wind-furnaces arises from the increased elasticity of that portion of air which is contained in the upper cavity of the fire-place, it being there heated by the fire, and naturally caused to expand. When this air rises by its increased elasticity, the denser and colder air below the grate must, of course, force its way to the hearth, blow up the fire, and thus maintain the combustion. It is obvious that, the air being rarer in the upper regions of the atmosphere, the higher the chimney in a close air or wind-furnace, the stronger will be the draught; that is, the air in the upper part of the chimney being exceedingly rarefied by the heat, and the atmospheric air at the vent or upper orifice of the chimney being rarer than the air below, there will be less resistance to the stream of rarefied air. The cold and dense air from below will therefore rush violently towards the ash-pit, to restore the equilibrium, and will penetrate through the fire, which it thus furnishes with a constant supply of fresh oxygen gas (the proper food of fire), and becoming rarefied in its turn by the accession of caloric, will force its way up the chimney, and thus a continual circulation is maintained, which will support almost any degree of heat while there is a regular supply of fuel, if the chimney is of a considerable height. It is evident that the size of the ash-hole should not be too large, but bear a proportion to the height of the chimney.

The perfection of a wind-furnace therefore consists, 1, in a good current of air; 2, in keeping the heat together, without losing too great a quantity of it unused; and, 3, in the facility with which the heat may be increased or weakened. The heat in wind-furnaces is increased, partly by an additional supply of fuel, partly by accelerating the draught of air. The last is effected by opening the door of the ash-pit wider, by shutting that of the fire-place, by opening the registers, and lengthening the chimney by additional vent-pipe, and also occasionally by applying the action of the bellows. The heat again is diminished by diminishing the quantity or celerity of the current of air; hence, by shutting the ash-hole, the registers, and vent-pipes, and by the proper application of these means the action of fire is weakened, or thoroughly suppressed.

Blast-furnaces increase the heat upon the same principle, by bringing in contact with the fuel of a fresh supply of oxygen, but this being effected by mechanical means, viz. by bellows, they are of a simpler construction than wind-furnaces, and their ash-pit, hearth, and laboratory, are commonly but one and the same part. The blowing is most frequently effected by bellows, which for small experiments are always made of leather, and to act without interruption, should be double. At the smelting works, wooden bellows are used; but these being single, there are always at the same time two of them employed, alternately opening and shutting. The cylinder-bellows are a discovery of modern times, and exceed the common by many advantages. Water-drums, as they are called, may likewise serve for these purposes.

When the vessels in which bodies are exposed to the action of heat are not placed in immediate contact with the fire in the wind-furnace, but receive the required degree of heat by another intermediate body, such apparatus is called a bath. The proper instrument for this purpose is the sand-furnace, or a wind-furnace, whose upper aperture is shut by the sand-pot. Sand-pots are cylindrical vessels, having an outwardly convex bottom, and made of cast or sheet-iron, and at times of baked clay. Glass vessels, however, containing bodies that are to be exposed to heat, are not placed in the pot while empty; but in order that they may be heated uniformly, this last is filled with some other body, into which the vessels are lodged. The matter most commonly employed in this case is dry, finely sifted sand; and the pot filled with it is called a sand-bath. Of all baths the sand-bath is the most convenient, and sufficient to apply any degree, from gentle warmth to red-heat. Crucibles placed between coals, are also used for a sand-bath instead of sand-pots.

If vessels are heated by means of hot water, in which they are immersed, it is called a water-bath, balneum mariæ; but if they are heated merely by the steam of boiling water, it is called a vapour-bath. Since water boiling in the open air is capable of receiving only a determinate degree of heat, it becomes thereby a sure means to impart heat, without danger of exceeding a certain degree.

Furnace, *glass painters*, is made of brick, nearly square, and about 2½ feet each way. It is cut horizontally in the middle by a grate, which sustains the pan or shovel the glass is baked in. This furnace has two apertures, one below the grate, to put the fuel in at; the other above it, through which the workman spies how the action of the colours goes on.

Furnaces, *haiters*, are of three kinds: a little one under the mould, whereon they form their hats; a larger in the scouring-room, under a little copper, full of lees; and a very large one under the great copper, wherein they dye their hats.

FURR, in commerce, signifies the skin of several wild beasts, dressed in alum with the hair on, and used as a part of dress by princes, magistrates, and others. The kinds most in use are those of the ermine, sable, castor, hare, rabbit, &c.

Furrs, in heraldry, a bearing which represents the skins of certain beasts, used as well in the doublings of the mantles belonging to the coat-armours, as in the coat-armour themselves.

FURZE, or *furze-bush*. See Ulex.

FUSANUS, a genus of the polygamia monœcia class and order. The herm. callyx is five-cleft; corolla none; stamina four; germen inferior; stigma four drupe. Male calyx, &c. the same. Fruit abortive. There is one species, a tree of the Cape.

FUSEE, in clock-work, is that part drawn by the spring, and about which the chain or string is wound. See Clock and Watch-work.

FUSES, in artillery, according to captain George Smith, formerly inspector to the military academy at Woolwich, are chiefly made of very dry beech wood, and sometimes of horn-beam taken near the root. They are turned rough and bored at first, and then kept for

several years in a dry place. The diameter of the whole is about $\frac{3}{4}$ of an inch; the hole does not go quite through, having about $\frac{1}{4}$ of an inch at the bottom; and the head is made hollow in the form of a bowl.

The composition for fuses is, saltpetre 3, sulphur 1, and mealed powder 3, or 4, and sometimes 5. This composition is driven in with an iron driver whose ends are capped with copper, to prevent the composition from taking fire; and to keep it equally hard; the last shovel-full being all mealed powder, and 2 strands of quick match laid across each other, being driven in with it, the ends of which are folded up into the hollow top, and a cap of parchment tied over it until it is used.

FUSILEERS, in the British service, are soldiers armed like the rest of the infantry, with this difference only, that their musquets are shorter and lighter than those of the battalion and the grenadiers. They wear caps which are somewhat less, in point of height, than common grenadier caps. There are three regiments in the English service; the royal regiment of Scotch fusileers, raised in 1678; the royal regiment of Welch fusileers, raised in 1685; and the royal regiment of Welch fusileers, raised in 1688-9.

FUSILY, or *fusile*, in heraldry, signifies a field or ordinary, entirely covered over with, or divided into fusils.

FUSION, the action of fire, or more properly, of caloric, on solid bodies, by which they are caused to pass into the state of fluidity; and a body rendered liquid by fire is said to be in fusion, to flow, to melt.

From the difference between solid and fluid bodies, it follows, that the active expansive power of the caloric is the principal or true cause of fusion; since, by combining with the solid substance, it diminishes and destroys, in a high degree, the attractive force of its particles. The fluidity of all liquid bodies, we know at present, is merely derivative, and the effect of the influx of caloric.

If we attend to the different strength of the attractive power which the particles of substances, specifically different, exert on one side amongst themselves, and on the other towards the caloric, we find no ground to wonder why some bodies require a lower, others a higher, temperature to be fused; and that it is possible to meet with some bodies, which at any degree of temperature we hitherto know in our atmosphere, continue in the liquid state. According to the various degrees of fusibility, bodies are discriminated into refractory, or of difficult fusion, which require the utmost violence of fire to be melted; and simply fusible, or of easy fusion, that will flow in less heat; yet the limits between these have not yet been ascertained by any fixed scale.

Some mixtures melt with greater ease than the single substances of which they are composed.

Some bodies cannot be rendered fluid by any degree of heat which we are able to produce. These are called infusible, apyrous or fire-proof. Several of them may, however, be fused by adding other bodies, which on account of this property are called fluxes. Such addition is called at the smelting-works dressing of the ores. It is worth remarking, that sometimes these additions are of themselves infusible.

The true fusion ought not to be confounded with the melting of some salt crystals by heat. The last is caused by the aqueous particles contained in them dissolving the salt at an increased heat, which they cannot at a weaker.

When melted bodies, by a circumambient medium of a lower temperature, are deprived of so much caloric that the original attractive forces of the bodies of which they are compounded, acquire again the degree of intensity requisite to produce the form of solidity; or when by this loss of caloric, the native attraction among the surfaces of the primitive molecules becomes again active, they concrete, or congeal.

All bodies must, in consequence of the explanation given of fusion, assume in fusion a greater volume than that which they had in their former state of solidity. This is in every respect confirmed by experience. The exception which some bodies, as ice, bismuth, antimony sulphur, seem to make, may be easily explained by the crystallization of their parts on concreting.

Since no solution takes place without liquidity, fusion becomes one of the most effectual operations for solutions and precipitations in the dry way. Fusion is, besides, of importance in separating heterogeneous parts simply mingled by means of their different degrees of fusibility; as also by the circumstance, that various shapes may be given to bodies by casting them into moulds while in a fluid state.

Fusion is sometimes performed without any vessel at all, and then in small quantities, by the flame of a candle or lamp, with the assistance of the blow-pipe: but, in larger quantities, by placing the bodies to be fused amongst the coals in a melting furnace. At other times, the operation is done in vessels, subjected to the requisite heat, in the furnace.

When the blow-pipe made of glass or metal, is employed, the air compressed by the mouth is directed on the flame; and the heat, by that means increased, is communicated to the substance to be fused, which generally rests on a support, in a cavity made in a lump of charcoal. The apparatus by which the air is made to stream through the blow-pipe, by means of double bellows, renders this useful instrument capable of being employed by persons whose lungs do not permit them to continue the blowing long, or who are not sufficiently skilled in its management. Lastly, the heat of a lamp-flame may be raised to the highest degree, by conducting oxygen gas through the blow-pipe, by means of a peculiar apparatus.

In smelting-houses, the fusion without vessels is performed in a very simple way, by placing the substances to be fused immediately betwixt burning charcoal in the melting-furnaces. In these the fusion is urged by bellows; and they are of various constructions, to suit a variety of purposes. Hence also they have received different denominations.

Other kinds of fusion, especially in small quantities, are performed in vessels of various shape and materials. Their most essential properties, are their being infusible at any degree of heat required for melting the bodies to be fused in them; and, besides, their insolubility in that body when melted.

FUSTIAN, in commerce, a kind of cotton stuff, which seems as if it was whaled on one side.

FUTTOCKS, in a ship, the timbers raised over the keel, or the encompassing timbers that make her breadth.

Of these are first, second, third, and fourth, denominated according to their distance from the keel, those next it being called first or ground futtocks, and the others upper futtocks: those timbers, being put together, make a frame-bend.

G.

G, the seventh letter of our alphabet; as a numeral was anciently used to denote 400; and with a dash over it thus, $\overline{G}$, 40,000. In music it is the character or mark of the treble cliff; and from its being placed at the head, or marking the first sound in Guido's scale, the whole scale took the name gamut. As an abbreviature, G. stands for Gaius, Gellius, gens, genius, &c. G. G. for gemina, gessit, gesserunt, &c. G. C. genio civitatis, or Cæsaris. G. L. for Gaius libertus, or genio loci. G. V. S. for genio urbis sacrum. G. B. for genio bono. And G. T. for genio tutelari.

GABARA, or *gabbara*, in antiquity, the dead bodies which the Egyptians embalmed, and kept in their houses, especially those of such of their friends as died with the reputation of great piety and holiness, or as martyrs.

GABEL, a word met with in old records, signifying a tax, rent, custom, or service, paid to the king, or other lord.

GABIONS, in fortification, baskets made of ozier-twigs, of a cylindrical form, six feet high, and four wide; which being filled with earth, serve as a shelter from the enemy's fire. See FORTIFICATION.

GABRES, or *gaurs*, in the religious custom of Persia. See Gaurs.

GAD, among miners, a small punch of iron, with a long wooden handle, used to break up the ore. One of the miners holds this in his hand, directing the point to a proper place, while the other drives it into the vein, by striking it with a sledge-hammer.

GAD-FLY, or *breeze-fly*. See OESTRUS.

GADOLINITE, a mineral first found in a white felspar in the quarry of Ytterby in Sweden, and received the name gadolinite, because Gadolin was the chemist who first ascertained its composition. Colour perfect black, passing sometimes to brown. Found in mass. Fracture conchoidal. Scratches quartz. Brittle. Specific gravity 4.0497. Gelatinizes with hot diluted nitric acid. Before the blow-pipe decrepitates, and assumes a whitish-red colour, but does not melt. With borax it melts into a topaz-yellow glass. Affects the magnetic needle. According to the Vanalysis of auquelin, it is composed of.

35.0	yttria
25.5	silica
25.0	oxide of iron
2.0	lime
2.0	oxide of manganese
10.5	water and carbonic acid
100.0	

Klaproth, on the other hand, found

59.75	yttria
21.25	silica
18.00	oxide of iron
0.50	alumina
99.50	

This last analysis does not differ much from that which Ekeberg had before published.

GADUS, cod, in ichthyology, a genus of fishes belonging to the order of jugulares. The generic character is, head smooth; gill-membrane, seven-rayed; body oblong, covered with deciduous scales; fins all covered by the common skin; dorsal and anal generally more than one; the rays unarmed; ventral fins slender, ending in a point. There are 17 species, the principal of which are,

1. Gadus morhua, or common cod. This highly important and prolific species, which furnishes employment for so many thousands, and forms so considerable a part of the subsistence of mankind, is an inhabitant of the northern seas, where it resides in immense shoals, performing various migrations at stated seasons, and visiting in succession the different coasts of Europe and America. Its history is so well detailed by Mr. Pennant, that little can be added to what that author has collected in his British and Arctic Zoology.

"The general rendezvous of the cod-fish," says Mr. Pennant, "is on the banks of Newfoundland, and the other sand-banks that lie off the coasts of Cape Breton, Nova Scotia, and New England. They prefer those situations on account of the quantity of worms produced in those sandy bottoms, which tempt them to resort thither for food; but another cause of this particular attachment to those spots is their vicinity to the polar seas, where they return to spawn: there they deposit their roe in full security, but want of food forces them, as soon as the first more southern seas are open, to repair thither for subsistence. Few are taken north of Iceland, but on the south and west coasts they abound: they are again found to swarm on the coasts of Norway, in the Baltic, off the Orkney and the Western isles; after which their numbers decrease, in proportion as they advance towards the south, when they seem quite to cease before they reach the mouth of the Straits of Gibraltar."

Before the discovery of Newfoundland, the greater fisheries of cod were on the seas of Iceland and our own Western isles, which were the grand resort of the ships of all the commercial nations; but it seems that the greatest plenty was met with near Iceland.

Newfoundland, a name in the infancy of discovery common to all North America, was discovered in the year 1496, by the celebrated Venetians, Sebastian Cabot and his three sons; who, at their own charges, under a grant of Henry the seventh, giving them possession, as vassals of his, of all lands they might discover, coasted from lat. 67° 30′ to the Cape of Florida.

The isle of Newfoundland is of a triangular form, and lies between lat. 46° 40′ and 51° 30′: visited occasionally, but not inhabited, by savages from the continent. The boasted mine of this land, viz. its sand-bank, is represented as a vast sub-marine mountain, of above 500 miles long, and near 300 broad, and seamen know when they approach it by the great swell of the sea, and the thick

mists that impend over it. The water on the bank is from twenty-two to fifty fathoms; on the outside from sixty to eighty; and on the smaller banks much the same: the increase of shipping that resort to these fertile banks is now unspeakable: England still enjoys the greatest share, and it ought to be esteemed one of it chiefest treasures, bringing wealth to individuals, and strength to the state. All this immense fishery is carried on by the hook and line only: the principal baits are herring, the small fish called a capelin, the shell-fish called clams, and pieces of sea-fowl; and with these are caught sufficient to find employ for fifteen thousand British seamen, and to afford subsistence to a much more numerous body of people at home, who are engaged in the various manufactures which so vast a fishery demands. The fish, when taken, are properly cleaned, salted, and dried, and in this state sent into various parts of the European continent.

The cod grows to a very large size. Mr. Pennant commemorates a specimen taken on the British coast which weighed 78 lbs. and measured 5 feet 8 inches in length, and 5 feet in girth round the shoulders; but the general size, at least in the British seas, is far less, and the weight from about 14 to 40 pounds; and such as are of middling size are most esteemed for the table.

The cod is of a moderately long shape, with the abdomen very thick and prominent: the head is of a moderate size, and the eyes large: the jaws of equal length, the lower one bearded at the tip by a single cirrus; in the jaws and palate are numerous sharp teeth: the dorsal and anal fins are rather large, the pectoral rather small: the ventral small and slender: the tail of moderate size and even at the end, the first ray on each side being short, strong, and bony. The usual colour of this fish is cinereous on the back and sides, and commonly spotted with dull yellow: the belly white or silvery; but the colours occasionally vary very considerably, and instances are often seen in which a yellow, orange, or even red tint prevails on the upper parts of the body, while the spots are lighter or deeper according to the different seasons in which the fish is taken: the lateral line, which is one of the principal distinctive marks of the species, is broad and whitish, and the scales are somewhat larger than in others of the genus.

The food of the cod is either small fish, worms, testaceous or crustaceous animals, such as crabs, large whelks, &c. its digestion is so powerful as to dissolve the greatest part of the shells it swallows; it is very voracious, catching at any small body it perceives moved by the water, even stones and pebbles, which are often found in the stomach. The fishermen are well acquainted with the use of the air bladder or sound of this fish, and dexterously perforate the living fish with a needle, in order to let out the air contained in that part; for without this operation the fish could not be kept under water in the well-boats, and brought fresh to market. The sounds when salted, are reckoned a delicacy, and are often brought in this state from Newfoundland. A species of isinglass is also prepared from this part of the fish by the natives of Iceland.

2. Gadus æglefinus, or haddock, is distinguished from the rest of this genus by having a forked tail, and the lower jaw longer than the upper: the colour of the body is silvery or white, with a dusky cast on the back: the lateral line is black, and on each side at some distance beyond the head, and above the pectoral fins, is a moderately large, squarish black spot: the tip of the lower jaw is furnished with a cirrus: the eyes are large; the scales small, round, and pretty closely attached to the skin.

This species is a native of the northern seas, where, like the cod, it assembles in prodigious shoals, visiting particular coasts at stated seasons; the shoals are sometimes near six miles in length, and more than a mile in breadth. "The grand shoal of haddocks," says Mr. Pennant, "comes periodically on the Yorkshire coasts. It is remarkable that they appeared in 1766 on the 10th of December, and exactly on the same day 1767. These shoals extended from the shore near three miles in breadth, and in length from Flamborough Head to Tinmouth castle, and perhaps much farther northwards. An idea may be given of their numbers by the following fact: three fishermen within the distance of a mile from Scarborough harbour frequently loaded their coble or boat with them twice a day, taking each time about a ton of fish: when they put down their lines beyond the distance of three miles from the shore they caught nothing but dog-fish, which shows how exactly these fish keep their limits. The best were sold from eight pence to a shilling per score, and the poor had the smaller sort at a penny, and sometimes a halfpenny per score." The haddock is taken in vast quantities about Heligoland, and thence sent to Hamburgh. In stormy weather this fish is said to imbed itself in the ooze at the bottom of the sea, none being taken in such weather; and those which are taken afterwards are observed to be covered with mud on their backs.

The haddock is, in general, of moderate size, measuring about eighteen inches or two feet in length: those which are most esteemed for the table weighing from two to four pounds; but it sometimes arrives at the length of three feet, and the weight of fourteen pounds. Its food consists of small fishes, worms, and sea-insects. It spawns in the month of February.

3. Gadus callarias, or dorse, is a somewhat smaller species than the haddock, those which are usually taken rarely exceeding the weight of two pounds.

The head is smaller than that of the haddock, and is marked by several spots, which in the summer are generally brown, and in the winter black: the general colour of the fish is cinereous above, and white beneath, several brown spots being scattered over the body, which, in the young fish, are often of an orange-colour: the scales are small, thin, and soft: the upper jaw is longer than the lower, and is furnished with more rows of teeth: at the tip of the lower jaw is a cirrus or beard.

The dorse is a native of the northern seas, as well as of the Mediterranean and the Baltic. It is taken both by the line and the net, and is highly esteemed as an article of food. It lives, like most others of this genus, on the smaller fishes, and sea-insects. Instances are adduced by authors in which this fish, like the haddock, has been found greatly to exceed the usual size, and to weigh seven, eight, ten, or even fourteen pounds. It spawns in the month of February.

4. Gadus barbatus, or whiting-pout, according to Mr. Pennant, never grows to a large size, rarely exceeding a foot in length, and is distinguished from all others by its great depth; one of the size above mentioned being near four inches deep in the broadest part: the back is very much arched, and carinated: the scales larger than those of the cod-fish: the mouth small, and the head short, on each side the lower jaw are seven or eight punctures: the first dorsal fin is triangular, and terminates in a long fibre: the colour of the fins and tail are dusky or blackish, and at the bottom of the pectoral fins is a black spot: the body is white, but more obscure on the back than the belly, and tinged with yellow: the lateral line is white, broad, and crooked. This fish is in high estimation as a food, and is found in the Mediterranean and northern seas.

5. Gadus minutus, or poor, is a small species, seldom exceeding six or seven inches in length, and of a more slender form than any of the preceding kinds. It is found in the Baltic and the Mediterranean, as well as in some parts of the northern seas. Its appearance in the Mediterranean, is considered by the fishermen as the precursor of the cod, and the haddock, of which it is supposed to indicate very plentiful shoals. It is reckoned a wholesome food, and is taken both by the line and net. It is supposed to feed chiefly on worms and sea-insects, and deposits its spawn among the stones and sea-plants towards the borders of the shore.

6. Gadus merlangus, or whiting, with three dorsal fins, as in the preceding kinds, but with a beardless mouth. The whiting is, according to Mr. Pennant, the most delicate as well as the most wholesome of the genus, but does not grow to a large size, the usual length being about ten or twelve inches, and the largest scarcely exceeding that of twenty. It is a fish of an elegant make: the body is rather long, and covered with small, round silvery scales: the head and back are of a pale brown, and the sides slightly streaked with yellow. This fish is an inhabitant of the Baltic, and the northern seas, and is found in some parts of the Mediterranean. Vast shoals appear in the British seas during the spring; keeping at the distance of from about half a mile to that of three from the shore; they are caught in vast numbers by the line, and afford excellent diversion: their food consists of small fishes, sea insects and worms: they are said to be particularly fond of sprats and young herrings, with which the fishermen generally bait for them, and in defect of these with pieces of fresh herring, one being sufficient, when cut, for twenty baits. According to Dr. Bloch, the chief time of the whiting fishery in France is in the months of January and February, though in England and Holland it is practised at a much later period. It spawns in December and January.

7. Gadus carbonarius, or coal-fish, when full grown, is, in general, readily distinguished from its congeners by its very dark or black colour, though in this respect it sometimes varies: it is of a moderately long and elegant shape, with a small head, sharpened snout, and lower jaw exceeding the upper in length: when full grown the head, dorsal fins, tail and upper parts of the body are of a dusky black, which gradually softens into a silvery tinge as it approaches the abdomen. It is an inhabitant of the Baltic, the northern and Mediterranean seas: it is common on the most of our rocky and deep coasts, but particularly on those of Scotland and the Orkneys, where, according to Mr. Pennant, it swarms, and where the young or fry forms a great part of the support of the poor.

8. Gadus merluccius, or hake, with two dorsal fins. The hake is of a considerably lengthened form: the head is rather large, broad and flat at the top, but compressed on the sides; the opening of the mouth wide, and the jaws armed with two rows of long, sharp-pointed, curved teeth, intermixed alternately with smaller ones: the palate is also furnished with a row of teeth on each side; the pectoral and ventral fins are of moderate size, and of a sharpened shape, and the tail is nearly even at the end; the lateral line commences by several small warts beyond the head, and is continued in a straight direction to the tail: the usual length of the hake is from one to two feet, but it is sometimes found of the length of three feet.

This fish is an inhabitant of the Mediterranean and northern seas, in both of which its fishery is very considerable: it is salted and dried in the manner of cod, haddock, &c. but is not considered as a delicate fish, either in its fresh or salted state, and is rarely admitted to the tables of the rich and luxurious: it forms however a very useful article of food for the lower orders in many parts both of England and other countries. It is found in vast abundance on many of the coasts of England and Ireland. We are informed by Mr. Pennant that there was formerly a vast stationary fishery of the hake on the Nymph Bank, off the coast of Waterford, immense quantities appearing there twice a year; the first shoal coming in June, during the mackarel season, and the other in September, at the beginning of the herring season, probably in pursuit of those fish: it was no unusual thing for six men with hooks and lines to take a thousand hake in one night, besides a considerable quantity of other fish. At present, as we are informed by Dr. Bloch, one of the greatest hake-fisheries is carried on about the coasts of Britanny, both by the hook and net. It is carried on chiefly by night, in boats properly manned for the purpose: the principal baits for such as are taken by the line are launces, sardines, and other small fishes.

9. Gadus molva, or the ling, takes its name from its length, being corrupted from the word long: the body is very slender; the head flat. The usual size of the ling is from three to four feet, but is said to have been sometimes seen of the length of seven feet: in colour it varies, being sometimes of an olive hue on the sides and back, and sometimes cinereous: the abdomen is white, as are also the ventral fins, and the dorsal and anal are edged with white: the tail is marked near the end with a transverse black bar, and tipped with white.

The ling is an inhabitant of the northern seas, and forms in many places a considerable article of commerce. It chiefly frequents the depths of the sea, living on small fishes, shrimps, &c. It spawns in June, depositing its eggs among the fuci on the oozy bottoms. In the Yorkshire seas the ling is in perfection from the beginning of February to the beginning of May, and some till the end of that month: as long as they continue in season the liver is very white, and abounds with fine flavoured oil; but as soon as the fish goes out of season the liver becomes red, and affords no more oil: the same circumstance is obser-

vable in several other fish in a certain degree, but not so remarkably as in the ling.

Vast quantities of this fish are salted for exportation as well as for home consumption. When it is cut or split for curing it must measure twenty-six inches, or upwards, from the shoulder to the tail; if less than that it is not reckoned a sizeable fish, and consequently not entitled to the bounty on exportation.

11. Gadus lota, or the burbot, highly esteemed for its superior delicacy, is an inhabitant of clear lakes and rivers, and is found in many parts of Europe and Asia. In England it occurs chiefly in the lakes of the northern counties, in some of the fens of Lincolnshire, and the rivers Witham and Trent; but it is said to arrive at its greatest perfection in the Lake of Geneva, where it is found in great plenty. In its habit or general appearance the barbot makes an obscure approach to the muræna, having a remarkably lengthened body of a subcylindric shape.

The burbot is considered as a very voracious fish, preying on all the smaller fishes, as well as on frogs, worms, and aquàtic insects: it grows to a considerable size: the largest however of those which are taken in England have been rarely known to exceed the weight of three pounds, but in some parts of Europe they are found of more than double that weight, and of the length of three feet or more. The reputation of this fish as a food has long been established, but its liver is celebrated as an article of peculiar luxury; and we are informed by Aldrovandus, that an old German countess carried her epicurism so far as to expend the greatest part of her income in the purchase of this dish. The gall has been famed, like that of the stargazer, the barbel, and some other fishes, for its supposed efficacy in external disorders of the eyes.

GÆRTNERE, a genus of the decandria monogynia class and order. The calyx is five-parted; corolla five-petalled; seed-vessel nearly globose, with wings. There is one species, a shrub of the East Indies.

GAGE, in law-books, the same with surety or pledge.

Gage, in the sea-language. When one ship is to windward of another, she is said to have the weather-gage of her. They likewise call the number of feet that a vessel sinks in the water, the ship's gage: this they find by driving a nail into a pike near the end, and putting it down beside the rudder till the nail catches hold under it; then as many feet as the pike is under water, is the ship's gage.

Gage, among letter-founders, a piece of box, or other hard wood, variously notched; the use of which is to adjust the dimensions, slopes, &c. of the different sorts of letters. There are several kinds of these gages, as the flat-gage, the face-gage, and italic-gage, &c.

Gage, *sliding*, a tool used by mathematical instrument-makers, for measuring and setting off distances. It is also of use in letter-cutting, and making of moulds.

Gage, *sea*, an instrument invented by Dr. Hayles, and Dr. Desaguliers, for finding the depth of the sea, the description of which is this. A B, (Plate LXIV. fig. 96. Miscel.) is the gage-bottle, in which is cemented the gage-tube E *f*, in the brass-cap at G. The upper end of the tube E, is hermetically sealed, and the open lower end *f*, is immersed in mercury, marked C, on which swims a small thickness or surface of treacle. On the top of the bottle is screwed a tube of brass H G, pierced with several holes, to admit the water into the bottle A B. The body K, is a weight, hanging by its shank L, in a socket N, with a notch on one side at *m*, in which is fixed the catch *l* of the spring *s*, and passing through the hole L, in the shank of the weight K, prevents its falling out, when once hung on. On the top, in the upper part of the brass-tube at H, is fixed a large empty ball, or full-blown bladder I, which must not be so large, but that the weight K may be able to sink the whole under water.

The instrument, thus constructed, is used in the following manner. The weight K being hung on, the gage is let fall into deep water, and sinks to the bottom; the socket N, is somewhat longer than the shank L, and therefore, after the weight K comes to the bottom, the gage will continue to descend, till the lower part of the socket strickes against the weight; this gives liberty to the catch to fly off the hole L, and let go the weight K; when this is done, the ball or bladder I, instantly buoys up the gage to the top of the water. While the gage is under water, the water having free access to the treacle and mercury in the bottle, will by its pressure force it up into the tube E *f*, and the height to which it has been forced by the greatest pressure, viz. that at the bottom, will be shown by the mark in the tube which the treacle leaves behind it, and which is the only use of the treacle. This shows into what space the whole air in the tube E *f* is compressed; and consequently the height or depth of the water, which by its weight produced that compression, which is the thing required.

If the gage-tube E *f*, is of glass, a scale might be drawn on it with a point of a diamond, showing by inspection, what height the water stands above the bottom. But the length of 10 inches is not sufficient for fathoming depths at sea, since that, when all the air in such a length of tube is compressed into half an inch, the depth of water is not more than 634 feet, which is not half a quarter of a mile.

If to remedy this, we make use of a tube 50 inches long, which for strength may be a musquet-barrel, and suppose the air compressed into an hundreth part of half an inch; by saying as 1 : 99 : : 400 : 396000 inches, or 3300 feet: even this is but little more than half a mile, or 2640. But since it is reasonable to suppose the cavities of the sea bear some proportion to the mountainous parts of the land, some of which are more than three miles above the earth's surface, therefore, to explore such great depths, the Doctor contrived a new form for his sea-gage, or rather for the gage-tube in it, as follows: B C D F (fig. 97.) is a hollow metallic globe communicating on the top with a long tube A B, whose capacity is a ninth part of that globe. On the lower part at D, it has also a short tube D E, to stand in the mercury and treacle. The air contained in the compound gage-tube is compressed by the water as before; but the degree of compression, or height to which the treacle has been forced, cannot here be seen through the tube; therefore, to answer that end, a slender rod of metal or wood, with a knob on the top of the tube A B, will receive the mark of the treacle, and show it, when taken out.

If the tube A B be 50 inches long, and of such a bore

that every inch in length shall be a cubic inch of air, and the contents of the globe and tube together 500 cubic inches; then, when the air is compressed within an hundredth part of the whole, it is evident the treacle will not approach nearer than 5 inches of the top of the tube, which will agree to the depth of 3300 feet of water as above. Twice this depth will compress the air into half that space nearly, viz. $2\frac{1}{2}$ inches, which correspond to 6600, which is a mile and a quarter. Again, half that space, or $1\frac{1}{4}$ inch, will show double the former depth, viz. 13200 feet, or $2\frac{1}{2}$ miles, which is probably very nearly the greatest depth of the sea.

*Bucket-sea-*Gage, an instrument contrived by Dr. Hales, to find the different degrees of coolness and saltness of the sea, at different depths; consisting of a common houshold pail or bucket, with two heads to it. These heads have each a round hole in the middle, near four inches diameter, and covered with valves opening upwards; and that they might both open and shut together, there is a small iron-rod fixed to the upper part of the lower valve, and at the other end to the under part of the upper valve: so that as the bucket descends with its sinking weight into the sea, both the valves open by the force of the water, which by that means has a free passage through the bucket. But when the bucket is drawn up, then both the valves shut by the force of the water at the upper part of the bucket; so that the bucket is brought up full of the lowest sea-water to which it had descended.

When the bucket is drawn up, the mercurial thermometer, fixed in it, is examined; but great care must be taken to observe the degree at which the mercury stands, before the lower part of the thermometer is taken out of the water in the bucket, else it would be altered by the different temperature of the air.

In order to keep the bucket in a right position, there are four cords fixed to it, reaching about four feet below it, to which the sinking weight is fixed.

*Wind-*Gage, an instrument for measuring the force of the wind upon any given surface. It was invented by Dr. Lind, who gives the following description of it, Phil. Trans. vol. lxv. This instrument consists of two glass tubes, A *a*, C D, Plate LXIV. Miscel. fig. 98. of five or six inches in length. Their bores, which are so much the better for being equal, are about four-tenths of an inch in diameter. They are connected together like a siphon, by a small bent glass-tube marked *a b*, the bore of which is about one-tenth of an inch in diameter. On the upper end of the leg A *a* there is a tube of latten brass, which is kneed or bent perpendicularly outwards, and has its mouth open towards F. On the other leg C D is a cover with a round hole G in the upper part of it, two-tenths of an inch in diameter. This cover and the kneed tube are connected together by a slip of brass *c d*, which not only gives strength to the whole instrument, but also serves to hold the scale H I. The kneed tube and cover are fixed on with hard cement or sealing-wax. To the same tube is soldered a piece of brass *e*, with a round hole in it to receive the steel spindle K L; and at *f* there is just such another piece of brass soldered to the brass-hoop *g*, which surrounds both legs of the instrument. There is a small shoulder on the spindle at *f*, upon which the instrument rests, and a small nut at *i*, to prevent it from being blown off the spindle by the wind. The whole instrument is easily turned round upon the spindle by the wind, so as always to present the mouth of the kneed tube towards it. The end of the spindle has a screw on it, by which it may be screwed into the top of a post or a stand made on purpose. It has also a hole at L, to admit a small lever for screwing it into wood with more readiness and facility. A thin plate of brass *k* is soldered to the kneed tube, about half an inch above the round hole G, so as to prevent rain from falling into it. There is likewise a crooked tube A B, fig. 99, to be put occasionally upon the mouth of the kneed tube F, in order to prevent rain from being blown into the mouth of the wind-gage when it is left out all night or exposed in the time of rain.

The force or momentum of the wind may be ascertained by the assistance of this instrument, by filling the tubes half full of water, and pushing the scale a little up or down, till the 0 of the scale, when the instrument is held up perpendicularly, be on a line with the surface of the water in both legs of the wind-gage. The instrument being thus adjusted, hold it up perpendicularly, and, turning the mouth of the kneed tube towards the wind, observe how much the water is depressed by it in the one leg, and raised in the other. The sum of the two is the height of a column of water which the wind is capable of sustaining at that time; and every body that is opposed to that wind will be pressed upon by a force equal to the weight of a column of water having its base equal to the altitude of a column of water, sustained by the wind in the wind-gage. Hence the force of the wind upon any body where the surface opposed to it is known may be easily found; and a ready comparison may be made betwixt the strength of one gale of wind and that of another.

The force of the wind may be likewise measured with this instrument, by filling it until the water runs out at the hole G. For if we then hold it up to the wind as before, a quantity of water will be blown out; and if both legs of the instrument are of the same bore, the height of the column sustained will be equal to double the column of water in either leg, or the sum of what is wanting in both legs. But if the legs are of unequal bores, neither of these will give the true height of the column of water which the wind sustained. But the true height may be obtained by the following formulæ.

Suppose that after a gale of wind which had blown the water from A to B, fig. 100, forcing it at the same time through the other tube out at E, the surface of the water should be found standing at some level as DG, and it were required to know what was the height of the column EF or AB, which the wind sustained. In order to obtain this, it is only necessary to find the height of the columns DB or GF, which are constantly equal to one another; for either of these, added to one of the equal columns AD, EG, will give the true height of the column of water which the wind sustained. 1. Let the diameters AC, EH, of the tubes, be respectively represented by *cd*; and let $a = AD$ or EG, and $x = DB$ or GF; then it is evident, that the column DB is to the column EG, as c^2x to d^2a. But these colums are equal. Therefore $c^2x = d^2a$; and consequently $x = \frac{d^2a}{c^2}$. But if, at any instant of

time whilst the wind was blowing, it was observed, that when the water stood at E, the top of the tube out of which it is forced, it was depressed in the other to some given level BF, the altitude at which it would have stood in each had it immediately subsided, may be found in the following manner. Let $b = AB$ or EF. Then it is evident that the column DB is equal to the difference of columns EF, GF. But the difference of these columns is as $d^2b - d^2x$; and consequently $x = \frac{d^2b}{c^2 + d^2}$.

For the cases when the wind blows in at the narrow leg of the instrument: Let $AB = EF = b$, EG or $AD = a$, $GF = DB = x$, and the diameters EH, CA, respectively $= d, c$, as before. Then it is evident, that the column AD is to the column GF as ac^2 to d^2x. But these columns are equal; therefore $d^2x = ac^2$; and consequently $x = \frac{ac^2}{d^2}$. It is also evident, that the column AD is equal to the difference of the columns AB, DB; but the difference of these columns is as $bc^2 - c^2x$. Therefore $d^2x = bc^2 - c^2x$. Whence we get $x = \frac{bc^2}{d^2 + c^2}$.

The use of the small tube of communication *a b*, fig. 98. is to check the undulation of the water, so that the height of it may be read off from the scale with ease and certainty. But it is particularly designed to prevent the water from being thrown up to a much greater or less altitude, than the true height of the column which the wind is able at that time to sustain, from its receiving a sudden impulse whilst it is vibrating either in its ascent or descent. As in some cases fresh water in this instrument might be liable to freeze, and thus break the tubes, Dr. Lind recommends a saturated solution of sea-salt to be used instead of it, which does not freeze till Fahrenheit's thermometer falls to 0.

Tide-GAGE, an instrument used for determining the height of the tides by Mr. Bayley, in the course of a voyage towards the south pole, &c. in the Resolution and Adventure, in the years 1772, 1773, 1774, and 1775. This instrument consists of a glass tube, whose internal diameter was 7-10ths of an inch, lashed fast to a 10 foot fir rod, divided into feet, inches, and parts, the rod being fastened to a strong post fixed firm and upright in the water. At the lower end of the tube was an exceedingly small aperture, through which the water was admitted. In consequence of this construction, the surface of the water in the tube was so little affected by the agitation of the sea, that its height was not altered the 10th part of an inch when the swell of the sea was 2 feet; and Mr. Bayley was certain, that with this instrument he could discern the difference of the 10th of an inch in the height of the tide.

GAHNIA, a genus of the monogynia order, in the hexandria class of plants. The calyx is an involucrum with two or five flowers; the corolla is two-valved; the stamina six capillary and very short filaments; the antheræ linear, sharp-pointed at the apex, and as long as the corolla; there is no pericarpium: the seed is single and oblong. There are two species, herbs of New Zealand and Otaheite.

GAIANITES, *gainaitæ*. in church history, a branch of eutychians.

GALBULA, in ornithology, a genus of the order picæ, bill straight, very long, quadrangular, pointed; nostrils oval, at the base of the bill: tongue short, sharp-pointed; thighs downy on the forepart. The viridis inhabits the moist woods of Guinea and Brazil; the size of a lark: it feeds on insects. There are three other species, viz. the grandis, the paradisea and albirostris.

GALANGALS, the name of two roots kept in the shops, a greater and a smaller; of which the smaller is by far most esteemed. See MATERIA MEDICA.

GALANTHUS, the SNOW-DROP, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the ninth order, spathaceæ. There are three concave petals; and the nectarium consists of three small emarginated petals; the stigma is simple. There is but one species, viz. the nivalis: which is a bulbous rooted flowery perennial, rising but a few inches in height, and adorned at top with small tripetalous flowers of a white colour. There are three varieties, viz. the common single-flowered snow-drop, the semi double snow-drop, and the double snow-drop. They are beautiful little plants, and are much valued on account of their early appearance, often adorning the gardens early in the spring, when scarcely any other flower is to be seen, making a very ornamental appearance especially when disposed in clusters towards the fronts of the borders, &c. The single kind comes first into bloom, then the semi-double, and after that the double. They will succeed any where, and multiply exceedingly by off-sets from the roots.

GALARDIA, a genus of the class and order syngenesia polygamia frustranea. The recept. is chaffy; seed crowned with five-leaved calycle; cal. two-rows of scales, almost equal. There is one species; an annual of Louisiana.

GALAX, a genus of the pentandria monogynia class and order. The cal. is ten-leaved; cor. silver-shaped; caps. one-celled, two-valved, and elastic. There is one species, an herb of Virginia.

GALAXIA, a genus of the monodelphia triandria class and order. The spethe. is one-valved; cor. one-petalled, six-cleft; tube capillary; stigma many parted. There are two species, herbs of the Cape.

GALAXY, in astronomy, the via lactea, or milky way of the heavens: a tract of a whitish colour, and considerable breadth, which runs through a great compass of the heavens, sometimes in a double, but for the greatest part of its course in a single stream; and is composed of a vast number of stars, too minute or too remote from the earth, to be distinguished by the naked eye; but are discovered in all parts of it, in great numbers, by the assistance of the telescope. See ASTRONOMY.

GALBANUM, a gum issuing from the stem of an umbelliferous plant, growing in Persia and many parts of Africa.

It is sometimes met with in the shops in loose granules, called drops or tears, and sometimes in large masses, formed of a number of these blended together; but in these masses some accidental foulness is often mixed with the gum. The single drops usually approach to a round-

ish, oblong, pearlike form. Galbanum is soft like wax, and, when fresh drawn, white; but it afterwards becomes yellowish or reddish: it is of a strong smell, of an acrid and bitterish taste; it is inflammable in the manner of a resin, and soluble in water like a gum. It attenuates and dissolves tough phlegm, and is therefore of service in asthmas and inveterate coughs: it is also of great service in hysteric complaints; it dissipates flatulencies. It is given in pills and electuaries, and is used externally in form of a plaster, applied to the abdomen, against habitual hysteric complaints, and on many other occasions.

GALEASSE, a large low-built vessel, using both sails and oars, and the largest of all the vessels that make use of the latter. It may carry twenty guns, and has a stern capable of lodging a great number of marines. It has three masts, which are never to be lowered or taken down. It has also thirty-two benches of rowers, and to each bench six or seven slaves, who sit under cover. This vessel has latterly been only used by the Venetians.

GALEGA, a genus of the class and order diadelphia decandria. The cal. has tubulate teeth nearly equal; legume with streaks between the seeds. There are 19 species, some of them known by the name of goat's rue.

GALENIA, a genus of the digynia order, in the octandria class of plants, and in the natural method ranking under the 13th order, succulentæ. The calyx is trifid; there is no corolla; the capsule is roundish and dispermous. There are two species, shrubs of the Cape.

GALENIC, or Galenical, in pharmacy, a manner of treating diseases founded on the principles of Galen. The distinction of galenical and chemical, was occasioned by a division of the practitioners of medicine into two sects, which happened on the introduction of chemistry into medicine; then the chemists, arrogating to themselves every kind of merit and ability, stirred up an opposition to their pretensions, founded on the invariable adherence of the other party to the ancient practice. And although this division into two sects of galenists and chemists has long ceased, yet the distinction of medicines which resulted from it is still retained.

Galenical medicines are those which are formed by the easier preparations of herbs, roots, &c. by infusion, decoction, &c. and by combining and multiplying ingredients; while those of chemistry draw their more intimate and remote virtues by means of fire and elaborate preparations, as calcination, digestion, fermentation, &c.

GALENISTS, in church history, a branch of anabaptists, who are said to have adopted several arian opinions concerning the divinity of our Saviour.

GALENA, in mineralogy, sulphuret of lead, is very common, and is found both in masses and crystallized. The primitive form of its crystals is a cube. The most common varieties are the cube, sometimes with its angles wanting, and the octahedron, composed of two four-sided pyramids applied base to base. The summits of these pyramids are sometimes cuneiform, and sometimes their solid angles are wanting.

Its colour is commonly blueish grey like lead, but brighter. Streak blueish grey and metallic. Lustre metallic. Sometimes stains the fingers. Texture foliated. Fragments cubical. Soft; but brittle. Specific gravity 7.22 to 7.587. Effervesces with nitric and muriatic acids. Before the blow-pipe decrepitates, and melts with a sulphureous smell; part sinks into the charcoal. It is composed of from .45 to .83 lead, and from .086 to .16 of sulphur. It generally contains some silver, and sometimes also antimony and zinc.

To this species is to be referred a mineral which occurs but rarely, called

Compact galena. Found in mass; sometimes in specular plates. Texture compact. Fracture even. Softer than common galena. Specific gravity 7.444. Streak lead grey, brighter, and metallic. Feels soft, and stains the fingers. Fragments indeterminate. Found in Derbyshire, and in different parts of Germany and Italy. Often mistaken for plumbago or molybdena. Another species is

Blue lead ore. This ore has hitherto been observed only at Zschopau in Saxony. It occurs rarely in mass, usually crystallized in small six-sided prisms. Colour between indigo blue and lead grey; sometimes inclining to black. Usually striated longitudinally. Internal lustre metallic. Streak brighter. Texture compact. Specific gravity 5.461. Before the blow-pipe melts with a low blue flame and a sulphureous smell, and is easily reduced. It has not been analysed. Its crystals resemble those of phosphat of lead; but its component parts seem to be the same as those of galena. Brochan supposes it a phosphat converted into a galena by some unknown process. A third species is

Black lead ore. This ore is found in Saxony, Poland, Siberia, and in different parts of Britain. It occurs in mass, disseminated and cellular; but more frequently crystallized in six-sided prisms, which are generally truncated and confused. Colour greyish black. Streak greyish black. Brittle. Specific gravity from 5.744 to to 5.77. Before the blow-pipe it decrepitates, melts easily and is reduced.

GALEOPITHECUS. Colugo. A genus of quadrupeds. The generic character is front-teeth in the upper jaw none; in the lower six, short, broad, distant, pectinated; canine-teeth very short, triangular, broad, sharp, serrated; grinders four, truncated, and muricated with conical proturberances; flying-skin surrounding the body, limbs, and tail.

This singular animal, which, from its size and extraordinary conformation, claims a conspicuous place among the productions of nature, has but lately been examined with the degree of exactness necessary for ascertaining clearly its generic characters. It is to Dr. Pallas that we owe the exact knowledge of these particulars, and an accurate description, accompanied by good figures, may be found in the transactions of the Academy of Petersburgh for the year 1780.

Galeopithecus volans, the flying colugo, is a native of the Molucca and Philippine islands, where it is said to frequent woody places, and to feed principally on fruits. It almost constantly resides on trees, and makes use of its membranes in the same manner as the flying squirrel. In descending from the top of a tree, it spreads its membranes, and balances itself to the place it aims at in a gentle manner; but in ascending it uses a leaping pace. It has two young, which are said to adhere to its breasts by the mouth and claws. The whole length of the animal is about three feet: the breadth, when expanded, nearly the same: the tail is slender and about a span long. The

membrane, or expansile skin, by which it is enabled to fly, is continued, on each side, from the neck to the fore feet; thence to the hind feet; and again to the tip of the tail: it is not naked, like the skin of a bat's wing, but covered with fur, in the same manner as the body: the inner or lower side, however, appears membranaceous, and is marked by numerous veins and fibres dispersed through it. The whole upper side of the animal is generally of a deep ash-colour, most so in those which are full-grown, and blacker in the younger or less advanced specimens: the back also, in the full-grown animals, is crossed transversely with blackish lines; towards the edges, is commonly a tinge of yellowish, and the whole under side, both of the body and membrane, is of a yellowish colour. The head is long; the mouth rather small; the tongue, according to Dr. Pallas, fleshy, broad, rounded, attenuated on the edges, and ciliated with papillæ, as in the opossums: it is also slightly beset with papillæ on its surface. There are no fore-teeth in the upper jaw, but in the lower are six, which are short, broad, and pretty deeply pectinated, so as to resemble little combs on their upper part: the canine teeth, or at least those which Dr. Pallas considers as such, are shaped somewhat like the petrifactions known by the name of glossopetræ, being triangular, very broad at their base, very short, sharp-pointed, and serrated; the grinders, or molares, which are generally four, both above and below, are of an abrupt or truncated form, and roughened with conical protuberances. The ears are small, round, membranaceous, and marked internally by numerous semicircular transverse streaks, as in a bat. The legs are clothed with a soft yellow down: there are five toes on each foot, united by a common membrane, and terminating in large, thin, broad, very sharp crooked claws. This animal is said to be called by the Indians caguang, colugo, and gigua. It was first described by Bontius, in his History of Java. He informs us that it is found in Guzarat, in India; that it is a gregarious animal, and flies principally in the evening; and that its body is of the size of a cat, and is covered above with a soft, grey fur, like that of a rabbit; that the head is oblong, the ears small and round, and that it has five strong claws on each foot, by which it holds firmly whatever it seizes, and that it feeds chiefly on fruits. Camelli, in his enumeration of the animals of the Philippine isles, published by Petiver in the Philosophical Transactions, describes it as about the size of a cat, shaped like a monkey, but more slender, and of the length of about three spans from head to tail; but adds, that in some parts it arrives at a far larger size, so as to equal a Chinese umbrella in expanse. He describes the colour on the upper parts as dusky, and elegantly variegated with whitish streaks on the back, running beyond the body over the flying membrane; the face he compares to that of a monkey, and the manner of flight to that of a flying squirrel: Camelli adds, that the young adhere to the teats of the parent by their mouth and claws; but it is remarkable, that in his manuscript on this subject now preserved in the British Museum, he expressly asserts that the female is furnished with two sacs or pouches on her belly, in which she carries her young while sucking.

Linnæus, judging of this animal's place in systematic arrangements, from the figures and descriptions of authors, but not having had an opportunity of examining its generic characters himself, placed it in the genus Lemur, to which he supposed it most allied; but was careful, at the same time to observe, that, as its teeth had not been examined, its real genus was, of course, not determinable. By the count de Buffon it was, with unpardonable negligence, entirely omitted; nor was it till Dr. Pallas's description in the Petersburgh Transactions appeared, that its generic characters were ascertained.

GALILEANS, a sect of the Jews. Their founder was one Judas, a native of Galilee, from which place they derived their name. Their chief, esteeming it an indignity for the Jews to pay tribute to strangers, excited his countrymen against the edict of the emperor Augustus, which had ordered a taxation or enrolment of all the subjects of the Roman empire. They pretended that God alone should be owned as master and lord; and in other respects were of the opinions of the pharisees: but, as they judged it unlawful to pray for infidel princes, they separated themselves from the rest of the Jews, and performed their sacrifices apart.

GALIUM, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 47th order, stellatæ. The corolla is monopetalous and plain; and there are two roundish seeds. There are 48 species, of which the most remarkable are, the verum or yellow lady's bed-straw, and the aperine, clivers or goose-grass. The former has a firm, erect, brown, square, stem; the leaves generally eight in each whorl, linear, pointed, brittle, and often reflex; branches short, generally two from each joint, terminating in spikes of small yellow flowers. It grows commonly in dry ground and on road-sides. The flowers will coagulate boiling milk; and the best Cheshire cheese is said to be prepared with them. The French prescribe them in hysteric and epileptic cases. Boiled in alum-water, they tinge wool yellow. The roots dye a red not inferior to madder; for which purpose they are used in the island of Jura. In the Edinburgh Medical Commentaries we have accounts of some violent scorbutic complaints being cured by the juice of this plant. Sheep and goats eat the plant; horses and swine refuse it; cows are not fond of it. The aperine or clivers has a square, very rough, jointed, very weak stem, two, three, or four feet long, and adhesive: the branches are opposite; the joints hairy at the base. The expressed juice of this plant taken internally, and the bruised leaves applied by way of poultice, are said to have been used with success as a cure for the cancer. The effects are, however, uncertain: the course, it is said, often requires to be continued for nine or ten months.

GALL, in the animal œconomy, the same with bile. See PHYSIOLOGY.

GALL-BLADDER, called vesicula, and cystis fellea, is usually of the shape of a pear, and of the size of a small hen's egg. It is situated in the concave side of the liver, and lies upon the colon, part of which it tinges with its own colour. It is composed of four membranes, or coats: the common coat; a vesicular one; a muscular one, consisting of straight, oblique, and transverse fibres; and a nervous one, of a wrinkled or reticulated surface within, and furnished with an unctuous liquor. See ANATOMY.

The use of the gall-bladder is to collect the bile, first

secreted in the liver, and mixing with its own peculiar produce, to perfect it farther, to retain it together a certain time, and then to expel it.

Gall, in natural history, denotes any protuberance or tumour produced by the puncture of the insects on plants and trees of different kinds. Galls are of various forms and sizes, and no less different with regard to their internal structure. Some have only one cavity, and others a number of small cells communicating with each other. Some of them are as hard as the wood of the tree they grow on, whilst others are soft and spongy; the first being termed gall-nuts, and the latter berry-galls, or apple-galls.

The general history of galls is this: an insect of the fly-kind (See Cynips), is instructed by nature to take care for the safety of her young, by lodging her eggs in a woody substance, where they will be defended from all injuries: she for this purpose wounds the branches or leaves of a tree, and the lacerated vessels, discharging their contents, soon form tumours about the holes thus made. The hole in each of these tumours, through which the fly has made its way, may for the most part be found; and when it is not, the maggot inhabitant or its remains, are sure to be found within, on breaking the gall. It is to be observed, however, that in those galls which contain several cells, there may be insects found in some of them, though there is a hole by which the inhabitant of another cell has escaped.

Oak-galls put, in a very small quantity, into a solution of vitriol in water, though but a very weak one, give it a purple or vitriol colour; which, as it grows stronger, becomes black; and on this property depends the art of making our writing-ink, as also a great deal of those of dying and dressing leather, and other manufactures. See Ink, &c.

Gall-stones. See Concretions.

GALLATS, in chemistry: whether gallic acid is capable of forming crystallizable salts with the different bases, is still a problem which chemists have not resolved.

1. When the alkalies are dropt into a solution of gallic acid in water, or into a solution containing gallic acid, it assumes a green colour. This change is considered by Proust as the most decisive test of the presence of gallic acid. The same change of colour takes place when gallic acid is poured into barytes water, strontian water, or lime water, and at the same time a powder of a greenish brown colour precipitates. The green liquid which remains contains only gallic acid combined with the earth employed in the experiment. But if we attempt to evaporate it to dryness, the green colour disappears, and the acid is almost completely decomposed.

2. When magnesia is boiled with the infusion of nut-galls, the liquid becomes almost limpid, and assumes the same green colour as the former mixtures. From the experiments of Mr. Davy, it appears, that in this case all the extract of tan is separated from the infusion, together with a portion of the gallic acid; and that the liquid holds in solution nothing but a combination of that acid and magnesia. But in this case also the acid is decomposed, and the green colour disappears when we attempt to obtain the composition in a dry state.

3. When a small portion of alum is mixed with the infusion of nut-galls, it separates the whole of the tan and extract, and leaves the liquid limpid and of a very pale yellowish green colour. This liquid, by spontaneous evaporation, yields small transparent prismatic crystals, which, according to Mr. Davy, are supergallats of allumina. They afford the only instance of a gallat capable of existing in the state of crystals. The quantity of allumina is very small; two small to disguise the properties of the acid.

GALLEON, in naval affairs, a sort of ships employed by Spain in the commerce of the West-Indies. The Spaniards send annually two fleets; the one for Mexico, which they call the flota; and the other for Peru, which they call the galleons. By a general regulation made in Spain, it has been established, that there should be twelve men of war, and five tenders annually fitted out for the armada or galleons; eight ships of 600 tons burden each, and three tenders, one of 100 tons, for the island of Margarita, and two of 80 each, to follow the armada: for the New Spain fleet, two ships of 600 tons each, and two tenders of 80 each; and for the Honduras fleet, two ships of 500 tons each: and in case no fleet happened to sail any year, three galleons and a tender should be sent to New Spain for the plate. They are appointed to sail from Cadiz in January, that they may arrive at Porto Bello about the middle of April; where, the fair being over, they may take on board the plate, and be at Havannah with it about the middle of June; where they are joined by the flota, that they may return to Spain with the greater safety.

GALLERY, in fortification, a covered walk, across the ditch of a town, made of strong beams, covered over head with planks, and loaded with earth: sometimes it is covered with raw hides to defend it from the artificial fires of the besieged. See Fortification.

Gallery *of a mine*, is a narrow passage, or branch of a mine carried on under-ground to a work designed to be blown up. Both the besiegers and the besieged also, carry on galleries in search of each others mines, and these sometimes meet and destroy each other.

Gallery, in a ship, that beautiful frame, which is made in the form of a balcony, at the stern of a ship without board; into which there is a passage out of the admiral's or captain's cabin, and is for the ornament of the ship.

GALLEY, in naval affairs, a low-built vessel using both sails and oars, and commonly carrying only a main-mast and foremast, to be struck or lowered at pleasure.

GALLIAMBIC verse, in ancient poetry, a verse consisting of six feet, viz. an anapest or a spondee; an iambus, or an anapest, or a tribrach; an iambus; a dactyl; an anapest.

GALLIC acid, in chemistry, is obtained from the nut-gall which grows on some species of oak. In an infusion of galls made with cold water, a sediment is formed which on examination is found to have a crystalline form and an acid taste. By letting an infusion of galls remain a long time exposed to the air, and removing now and then the mouldy skin which formed on its surface, a large quantity of this sediment was obtained; which being edulcorated with cold water, redissolved in hot water, filtrated and evaporated very slowly, yielded an acid salt in crystals as fine as sand.

Mr. Davy has lately pointed out another method which

yields gallic acid in a state of considerable purity. Boil for some time a mixture of carbonat of barytes and infusion of nut-galls. A blueish green liquid is obtained, which consists of a solution of gallic acid and barytes. Filter and saturate with diluted sulphuric acid. Sulphat of barytes is deposited in the state of an insoluble powder, and a colourless solution of gallic acid remains behind.

Gallic acid, when pure, is in the form of transparent plates or octahedrons. Its taste is acid, and somewhat astringent; and when heated it has a peculiar and rather unpleasant aromatic odour.

It is soluble in one and a half parts of boiling water, and in 12 parts of cold water. When this solution is heated, the acid undergoes a very speedy decomposition. Alcohol dissolves one-fourth of its weight of this acid at the temperature of the atmosphere. When boiling hot, it dissolves a quantity equal to its own weight. It is insoluble in ether. When exposed to the action of heat, it is sublimed without alteration: but a strong heat decomposes it in part, and converts it into an acid water, carbureted hydrogen gas, carbonic acid gas, oil, and charcoal. When distilled, a quantity of oxygen gas is disengaged, an acid liquor is found in the receiver, with some gallic acid not decomposed, and there remains in the retort a quantity of charcoal. If what has passed into the receiver is again distilled, more oxygen gas is obtained, some gallic acid still sublimes, and a quantity of charcoal remains in the retort. By repeated distillations the whole of the acid may be decomposed. This decomposition may be more easily accomplished by distilling repeatedly a solution of gallic acid in water. The products are oxygen gas, charcoal, and an acid liquor.

From these experiments it was concluded, that gallic acid is composed of oxygen, and a much larger proportion of carbon than enters into the composition of carbonic acid. But this conclusion is not warranted by the analysis: for the quantity of oxygen gas and carbon obtained was not equal to that of the gallic acid decomposed; and in the acid liquor which came over, there evidently existed a quantity of water, which doubtless was formed during the distillation. Scheele, by treating gallic acid with nitric acid in the usual manner, converted it into oxalic acid. Now it is certain that oxalic acid contains hydrogen as well as carbon. It cannot be doubted, then, that gallic acid is composed of oxygen, hydrogen, and carbon, in proportions not yet ascertained. But Mr. Deyeux has proved, that the quantity of carbon is very great, compared with that of the hydrogen.

Gallic acid is not altered by exposure to the air. Neither oxygen gas, the simple combustibles, nor azote, seem to have any particular action on it. Its action on the metals has not been examined. It combines with alkalies, earths, and metallic oxides, and forms compounds called gallats, most of which are still but very imperfectly known.

As the greater number of its combinations with metallic oxides are insoluble, it for the most part occasions a precipitate when poured into a solution containing a metal; and this precipitate differs in colour, according to the metal which occasions it. Hence this acid, or at least the infusion of nut-galls, is very much used by chemists to detect the presence of metals when held in solution. The formation of a precipitate, with infusion of nut-galls, is even considered as a property almost peculiar to metallic oxides. It ought to be remarked, however, that all the metals are by no means precipitated from their solutions by gallic acid. The following must be excepted:

1. Platinum,	4. Cobalt,
2. Tin,	5. Manganese,
3. Zinc,	6. Arsenic.

The following Table exhibits a view of the colours of the precipitates of different metals by means of this acid:

Gold	Brown
Silver	Brown
Mercury	Orange yellow
Copper	Brown
Iron	Black
Lead	White
Nickel	Grey
Bismuth	Orange
Antimony	White
Tellurium	Yellow
Uranium	Chocolate
Titanium	Reddish brown
Chromium	Brown
Columbium	Orange

Molybdic acid acquires a dark yellow colour, but does not precipitate.

But the colour of these metallic precipitates varies considerably according to the state of oxydizement, and the acid with which they are composed. These differences are especially remarkable in the solutions of mercury and copper.

Gallic acid produces no change in the solutions of alkaline salts: but when dropt into barytes water, strontian water, or lime water, it gives them a blueish-red colour, and occasions a flaky precipitate, composed of the acid combined with the earths.

Gallic acid occasions a precipitate when poured into solutions of glucina, yttria, and zirconia in acids. This property distinguishes these three bodies from all the other earths, none of which are precipitated from their solutions in acids by gallic acid.

The affinities of gallic acid are still undetermined. Mr. Richter has shown, that it is not capable of taking iron from sulphuric acid, as has been hitherto supposed, unless it is assisted by the action of some other body which has an affinity for sulphuric acid. He has endeavoured to show, too, contrary to the experiments of Proust, that it strikes a black with all the oxides of iron; but his proofs are by no means sufficient to decide that point.

GALLINÆ, in ornithology, the fifth order of birds: the upper mandible is channelled, extending with a margin above the lower, and a little bowed; the nostrils are covered with a cartilaginous membrane; they live upon grain, dust themselves, make an artless nest and lay many eggs. Under this order are comprehended the peacock, pheasant, turkey, the common dunghill cock, partridge, grous, dodo, curissoa, &c.

GALLIUM, *ladies bed-straw*. See GALIUM.

GALLON, a measure of capacity both for dry and liquid articles, containing four quarts; but these quarts, and consequently the gallon itself, are different, accord-

ing to the quality of the thing measured; for instance, the wine gallon contains 231 cubic inches, and holds eight pounds five ounces and two-thirds avoirdupois, of pure water: the beer and ale gallon contains 282 solid inches, and holds ten pounds three ounces and a quarter avoirdupois, of water: and the gallon for corn, meal, &c. two hundred and sixty-eight cubic inches and four-fifths, and holds nine pounds eleven ounces and a half of pure water.

GALLOON, in commerce, a narrow thick kind of ferret or lace, used to edge or border clothes, sometimes made of wool, and at others of gold or silver.

GALOPINA, a genus of the tetandria digynia class and order. Cal. none; cor. four cleft; seeds two, naked. A plant of the Cape.

GALVANISM, a term used to denote the influence of metals by mere external contact with the animal body. In the year 1791, a very remarkable discovery made by Dr. Galvani of Bologna was announced to the scientific world in a publication entitled, Aloysii Galvani de Viribus Electricitatis in motu musculari Commentarius. Bononiæ 1791.

The discoveries of Galvani were made principally with dead frogs. He in the first place discovered that a frog dead and skinned, is capable of having its muscles brought into action by means of electricity, even in exceedingly small quantities.

Secondly, that independant of any apparent electricity, the same motions may be produced in the dead animal, or even in a detached limb, merely by making a communication between the nerves and the muscles, with substances that are conductors of electricity. If the circuit of communication consists of non-conductors of electricity, as glass, sealing-wax, and the like, no motion will take place. Similar experiments were also successfully instituted upon other animals; and as the power seemed to be inherent in the animal parts, those experiments, or the power which produces the motion of the muscles in those experiments, were denominated animal electricity. But it being now fully ascertained, that by the mere contact of metallic and other conducting substances, some electricity is generated, it is evident that the muscular motions in the above-mentioned experiments are produced by that electricity; hence we have confined the name of animal electricity to denote the power of the fishes which give the shock, &c. as described in a preceding article. (See Electricity.) And, at least for the present, we shall examine the electricity which is produced by the contact, or by the action, of metallic and other conducting substances upon each other, under the title of galvanism; though in truth Galvani's discoveries go no farther than what relates to certain effects of the contact of animal parts principally with metallic. We shall briefly describe the several facts which relate to the above-mentioned sort of muscular motion, and shall then proceed to those which refer to the wonderful effects of the mere contact or action of one conducting substance upon another, amongst which the metallic are the most conspicuous.

The action of electricity on a frog, recently dead and skinned, (and indeed on other animals more or less) occasions a tremulous motion of the muscles, and generally an extension of the limbs.

Dr. Galvani used to skin the legs of a frog recently dead, and to leave them attached to a small part of the spine, but separated from the rest of the body. Any other limb may be prepared in a similar manner: viz. the limb is deprived of its integuments, and the nerve which belongs to it is partly laid bare.

If the limbs thus prepared, for instance the legs of a frog, are situated so that a little electricity may pass through them, be it by the immediate contact of an electrified body, or by the action of electric atmospheres (as when the preparation is placed within a certain distance of an electrical machine, and a spark is taken from the prime conductor); the prepared legs will be instantly affected with a kind of spasmodic contraction, sometimes so strong as to jump a considerable way.

When the electricity is caused to pass through the prepared frog by the immediate contact of the electrified body, a much smaller quantity of it is sufficient to occasion the movements, than when it is made to pass from one conductor to another, at a certain distance from the prepared animal.

The movements are much stronger when the electricity is caused to pass through a nerve to the muscle or muscles, than through any other part.

The sensibility of the prepared animal is greatest at first, but it diminishes by degrees till it vanishes entirely. Animals with cold blood, and especially frogs, retain that sensibility for several hours, sometimes even for a day or two. With other animals the sensibility does not last long after death, and sometimes not above a few minutes.

The like movements may be produced in the prepared animal without the aid of any apparent electricity. In an animal recently dead, detach one end of a nerve from the surrounding parts, taking care to cut it not too near its insertion into the muscle; remove the integuments from over the muscles which depend on that nerve; take a piece of metal, as a wire, and touch the nerve with one extremity of it, and the muscles with its other extremity; on doing which you will find that the prepared limbs move in the same manner as when some electricity is passed through them. This, however, is not the most effectual way of forming the communication: yet it will generally succeed, and the experiment will answer whether the preparation is laid upon conductors or upon electrics.

If the communication between the nerve and the muscle is formed by the interposition of non-conductors of electricity, such as glass, sealing-wax, &c. then no movements will take place.

When the application of the metal or metals is continued upon the parts, the contractions will cease after a certain time, and on removing the metal, seldom, if ever, any contraction is observed.

The conducting communication between the muscle and the nerve may consist of one or more pieces, and of the same or, much better, of different bodies connected together, as metals, water, a number of persons, and even wood. But it must be observed, that the various bodies, which form this circuit, must be placed in full and perfect contact with each other, which is done by pressure, or by the interposition of water, &c. The less perfect conductors will answer only at first, when the

prepared animal is vigorous; but when the power begins to diminish, then the more perfect conductors only will answer, and even these will produce various effects.

The most effectual way of producing those movements in prepared animal parts is by the application of two metals, of which silver and zinc seem upon the whole to be best, though silver and tin, or copper and zinc, and other combinations, are not much inferior. If part of the nerve proceeding from a prepared limb is wrapped up in a bit of tin foil, or only laid upon zinc, and a piece of silver laid with one end upon the bare muscle, and with the other upon the above-mentioned tin or zinc, the motion of the prepared limb will be very vigorous. The two metals may be placed not in contact with the preparation, but in any other part of the circuit, which may be completed by means of other conductors, as water, &c.

The best preparation for this experiment is made in the following manner:

Separate with a pair of scissars the head and upper extremities of a frog from the rest of the body. Open the integuments and muscles of the abdomen, and remove the entrails, by which means you will lay bare the crural nerves. Then pass one blade of the scissars under the nerve, and cut off the spine with the flesh close to the thighs, by which means the legs will remain attached to the spine by the nerves alone. This done, leave a small bit only of the spine attached to the crural nerves, and cut off all the rest. Thus you will have the lower limbs G, H, (fig. 1, Plate LXI. Galvanism) of the frog adhering to the bit of spine A B, by means of the crural nerves C, D. These legs must be flayed in order to lay bare the muscles; and a bit of tin foil should be wrapped round the spine A B. With this preparation the experiment may be performed in various ways, but the two which follow are the best.

Hold the preparation by the extremity of one leg, the other leg hanging down, with the armed bundle of nerves and spine lying upon it. In this situation interpose a piece of silver, as a half-crown, between the lower thigh and the nerves, so that it may touch the former with one surface, and the metallic coating of the latter with the other surface, or with its edge; and you will find that the hanging leg will vibrate very powerfully, sometimes so far as to strike against the hand of the operator, which holds the other leg.

Otherwise, place two wine-glasses, both full of water, contiguous to each other, but not actually touching. Put the thighs and legs of the preparation in the water of one glass, and laying the nerves over the edges of the two glasses, let the bit of spine with its armour (viz. tin foil) touch the water of the other glass. Things being thus prepared, if you form the communication between the waters of the two glasses, by means of silver, or put the fingers of one hand into the water of the glass that contains the legs, and holding a piece of silver in the other, you touch the coating of the nerves with it, you will find that the prepared legs move so powerfully as sometimes to jump fairly out of the glass.

Fig. 2 represents a prepared frog suspended on a metallic wire, and parallel to the animal, a metallic chain. When the receiver x is exhausted, on pushing down the rod so that the nerve of the frog and the chain may touch the metallic plate z at the bottom, the frog is convulsed as in the open air.

By the application of armours of different metallic substances, and forming a communication between them, the motions may be excited even in an entire living frog, as also in some other living animals, particularly eels and flounders. The living frog is placed upon a piece of zinc, with a slip of tin foil pasted upon its back. This done, whenever the communication is formed between that zinc and the tin foil, especially if silver is used, the spasmodic convulsions are excited, not only in the muscles which touch the metallic substances, but likewise in the neighbouring muscles. This experiment may be performed entirely under water.

Fig. 3 represents a living frog placed in an exhausted receiver, the animal being tied to a plate of silver by a silken string, and having a piece of tin foil on its back. As often as the circuit is completed, the convulsions ensue.

The experiment may be performed with a flounder in a similar easy and harmless manner. Take a living flounder; wipe it pretty dry, and lay it flat on a pewter plate, or upon a sheet of tin foil; and place a piece of silver, as a shilling, a crown piece, &c. upon the fish. Then, by means of a piece of metal, complete the communication between the pewter plate or tin foil and the silver piece: on doing which the animal will give evident tokens of being affected.

It seems that such movements may be excited by the contact of metallic substances in all the animals; at least they have succeeded, but in different degrees, in a great variety of animals from the ox to the fly.

Fig. 4 shows the method of producing convulsions in cold-blooded animals, by the influence of warm-blooded animals. The right hand of the experimentalist is placed in the ear, previously moistened with salt and water, of an ox's head, while in the other hand a prepared frog is suspended by the foot, and the sciatic nerves brought into contact with the ox's tongue. Convulsions are immediately produced in the muscles of the frog.

The human body, whilst undergoing certain chirurgical operations, or its amputated limbs, have been convulsed by the application of metals. But the living animal body may be rendered sensible of the action of metallic application in an harmless way, and both the senses of taste and sight may be affected by it, but in different degrees according to the various constitutions of individuals.

Let a man lay a piece of metal, as zinc, upon his tongue, and a piece of some other metal, as silver, under the tongue; on forming the communication between those two metals, either by bringing their outer edges in contact, or by the interposition of some other piece of metal, he will perceive a peculiar sensation, a kind of irritation, accompanied with a sort of cool and subacid taste, not exactly like, and yet not much different from, that which is produced by artificial electricity. The sensation seems to be more distinct when the metals are of the usual temperature of the tongue. The silver or gold may be applied to any other part of the mouth, to the nostrils, to the ear, or to other sensible parts of the body, whilst the zinc is applied to the tongue; and on making the communication between the two metals, the taste will be perceived upon

the tongue. The effect is rather more remarkable when the zinc touches the tongue in a small part, and the silver in a great portion of its surface, than vice versa. Instead of the tongue, the two metals may also be placed in contact with the roof of the mouth, as far back as possible; and on completing the communication, the taste or irritation will be perceived.

Different persons are variously affected by this application of metals; with some the sensation or taste is so slight as to be hardly perceived, whilst with others it is very strong and even disagreeable. Some persons feel merely a pungency, and not properly a taste.

In order to affect the sense of sight by means of metals, let a man in a dark place put a slip of tin foil upon the bulb of one of his eyes, and let him put a piece of silver, as a spoon or the like, in his mouth. On completing the communication between the spoon and the tin foil, a faint flash of white light will appear before his eyes. This experiment may be performed in a more convenient manner, by placing a piece of zinc between the upper lip and the gums, as high up as possible, and a silver piece of money upon the tongue; or else by putting a piece of silver high up in one of the nostrils, and a piece of zinc in contact with the upper part of the tongue; for in either case the flash of light will appear whenever the two metals are made to communicate, either by the immediate contact of their edges, or by the interposition of other good conductors.

By continuing the contact of the two metals, the appearance of light is not continued, it being only visible at the moment of making the contact, and sometimes, though rarely, at the instant of separation: it may therefore be repeated at pleasure, by disjoining, and again connecting, the two metals. When the eyes are in a state of inflammation, the appearance of light is much stronger.

When the science was advanced no farther than the knowledge of the above-mentioned facts, it was doubtful whether the convulsions of prepared animal limbs, and the sensations which are produced by the application of metallic substances, were owing to some electrical property peculiar to the animal parts, which might perhaps be conducted through the metals from one part to the other; or to a small quantity of electricity, which might be supplied by the metals themselves. The latter supposition however was soon verified by the result of various experiments, which prove in the most convincing manner that electricity is produced by the mere contact, not only of metallic substances, but likewise of other bodies.

The electricity thus produced by the mere contact of bodies is so very small as not to be perceived without great care, and without using some of those artifices for discovering small quantities of electricity, which have been mentioned above. But the discoveries of the ingenious Mr. Volta have shown a method of increasing that electricity to a most extraordinary degree. We shall now proceed to state those facts in as compendious a manner as the nature of the subject will admit of.

The action of metallic substances upon the organs of living, or of recently dead animals, has been fully manifested by the above-mentioned discoveries of Galvani and others; but, previously to these discoveries, a variety of facts, frequently asserted, imperfectly known, and often disbelieved, indicated a peculiar action arising from a combination of different metallic bodies in certain cases.

It had been long asserted, that when porter (and some other liquors also) is drunk out of a pewter pot, it has a taste different from what it has when drunk out of glass or earthenware.

It has been observed, that pure mercury retains its metallic splendour during a long time; but its amalgam with any other metal is soon tarnished or oxidated.

The Etruscan inscriptions, engraved upon pure lead, are preserved to this day; whereas some medals of lead and tin, of no great antiquity, are much corroded. Works of metal, whose parts are soldered together by the interposition of other metals, soon tarnish about the places where the different metals are joined.

When the copper sheeting of ships is fastened on by means of iron nails, those nails, but particularly the copper, are readily corroded about the place of contact.

It had been observed that a piece of zinc might be kept in water for a considerable time, with hardly oxidating at all; but that the oxidation would soon take place if a piece of silver happened to touch the zinc, whilst standing in water.

Since Galvani's discoveries, the action arising from the combination of three conductors has been examined with great care, and with considerable success, especially by Mr. Volta, who lately discovered that the slight effect of such a combination may be increased to a prodigious degree by repeating the combination; for instance, if a combination of silver, zinc, and water, produce a certain effect, a second combination (viz. another piece of silver, another piece of zinc, and another quantity of water) added to the first, will increase the effect; the addition of a third combination will increase the effect still more, and so on.

Previously to the description of the construction of the very remarkable effects of those repeated combinations, which are now generally called galvanic batteries, it will be necessary to state the principal laws, which have been pretty well ascertained with respect to the simple combinations.

1. The conductors of electricity, which, strictly speaking, do almost all differ from each other in conducting power, are nevertheless divided into two principal classes. Those of the first class, otherwise called dry and perfect conductors, are the metallic substances and charcoal. Those of the second class, or the imperfect conductors, are water and other oxidating fluids, as also the substances which contain those fluids. But as the substances of the second class differ in conducting power much more than those of the first class, so they may be subdivided into species.

Mr. Volta arranges those substances in the following order, commencing with the least active; observing, however, that this order is subject to a considerable deviation, especially with respect to the latter species, and according as they are combined with certain bodies of the first class.

"1. Pure water; (it may be observed, that water holding in solution common air, and especially oxygen gas, is much more active than water deprived of air by boiling or otherwise.) 2. Water mixed with clay or chalk; 3. A solution of sugar; 4. Alcohol; 5. Milk; 6. Mucilagi-

nous fluids; 7. Animal gelatinous fluids; 8. Wine; 9. Vinegar and other vegetable juices and acids; 10. Saliva; 11. Mucus from the nose; 12. Blood; 13. Brains; 14. Solution of salt; 15. Soap suds; 16. Chalk-water; 17. Concentrated mineral acids; 18. Strong alkaline leys; 19. Alkaline fluids; 20. Livers of sulphur."

2. The simplest combinations capable of producing galvanic effects, (viz. to convulse the prepared limbs of a frog, or to excite the taste upon the tongue, &c.) must consist of three different conductors; for two conductors only will not produce any sensible effect. If the three conductors are all of the first class, or all of the second, then the effect is seldom sensible. In this case such conductors of the second class as differ more from each other, are more likely to produce a sensible effect than those of the first class. But a proper active simple combination must consist of three different bodies; viz. of one conductor of one class, and two different conductors of the other class. Thus (denoting the bodies of the first class by means of large capital letters, and those of the second class by small letters) the combinations of fig. 5 and 6, are active; but those of fig. 7, 8, 9, 10, and 11, are not active; because that of fig. 7, 8, or 9, consists of two bodies only, and that of fig. 10 or 11, consists of three bodies, of which two are of the same sort, and of course act as a single body.

When two of the three bodies are of the first class, and one is of the second, the combination is said to be of the first order; otherwise it is said to be of the second order.

In a single active galvanic combination, or, as it is commonly called, in a simple galvanic circle, the two bodies of one class must touch each other in one or more points, at the same time that they are connected together at other points by the body of the other class. Thus, when a prepared frog is convulsed by the contact of the same piece of metal in two different places; then the fluids of those parts, which must be somewhat different from each other, are the two conductors of the second class, and the metal is the third body, or the conductor of the first class. If two metals are used, then the fluids of the prepared animal, differing but little from each other, may be considered as one body of the second class. Thus also, when a person drinks out of a pewter mug, the saliva or moisture of his under lip is one fluid or one conductor of the second class, the liquor in the mug is the other, and the metal is the third body, or conductor of the first class.

3. It seems to be indispensably requisite, that in a simple galvanic circle, the conductor or conductors of one class should have some chemical action upon the other conductor or conductors; without which circumstance the combination of three bodies will have either no galvanic action at all, or a very slight one. Farther, the galvanic action seems to be proportionate to the degree of chemical agency; which seems to show that such chemical action is the primary cause of the electric phenomena.

The most active galvanic circles of the first order, are when two solids of different degrees of oxidability are combined with a fluid capable of oxidating at least one of the solids. Thus gold, silver, and water, do not form an active galvanic circle; but the circle will become active if a little nitric acid, or any fluid decomposable by silver, is mixed with the water.

A combination of zinc, silver, and water, forms an active galvanic circle; and the water is found to oxidate the zinc, provided the water holds some atmospheric air, as it commonly does. and especially if it contains oxygen gas. But zinc, silver, and water containing a little nitric acid, form a more powerful galvanic circle, the fluid being capable of acting both upon the zinc and upon the silver.

The most powerful galvanic combinations of the sesecond order, are when two conductors of the second class have different chemical actions on the conductors of the first class, at the same time that they have an action upon each other. Thus copper, or silver, or lead, with a solution of an alkaline sulphuret, and diluted nitrous acid, forms a very active galvanic circle.

The present state of knowledge relative to this subject, does not enable us actually to determine the particular powers of all sorts of galvanic combinations; the following lists, however, contain an useful arrangement of the best combinations, disposed in the order of their powers, and commencing with the most powerful.

Table of galvanic circles of the first order, viz. which consist of two conductors of the first class, and one of the second.

Zinc, with gold, or charcoal, or silver, or copper, or tin, or iron, or mercury; and water containing a small quantity of any of the mineral acids.

Iron, with gold, or charcoal, or silver, or copper, or tin, and a weak solution of any of the mineral acids, as above.

Tin, with gold, or silver, or charcoal, and a weak solution of any of the mineral acids, as above.

Lead, with gold, or silver, and a weak acid solution, as above.

Any of the above metallic combinations, and common water, viz. water containing atmospheric air, or especially water containing oxygen air.

Copper, with gold, or silver, and a solution of nitrate of silver and mercury; or the nitric acid; or the acetous acid.

Silver, with gold, and the nitric acid.

Table of galvanic circles of the second order, viz. which consist of one conductor of the first class, and two of the second.

Charcoal, or Copper, or Silver, or Lead, or Tin, or Iron, or Zinc,	with water, or with a solution of any hydrogenated alkaline sulphurets, capable of acting on the first three metals only;	and a solution of nitrous acid, or oxygenated muriatic acid, &c. capable of acting upon all the metals.

The action of a simple galvanic circle seems to be in some measure dependant upon the quantity of surface of contact between the acting bodies. A higher temperature, within certain limits, renders the activity of the circle greater than a lower temperature.

The activity of a galvanic circle is not altered by the interposition of such conductors as have no action upon the adjoining conductors of the circle. Thus, if a circle consists of zinc, gold, and water; and if you interpose a piece of iron, or of silver, or both, between the zinc and

the gold; the activity of the circle will not be altered. Hence it appears that the action of a galvanic circle may be conveyed through extraneous conductors to a considerable distance; but it must be observed, that the activity is weakened by the great length of the conductors, especially if they are of an imperfect nature.

4. When the three bodies which form a galvanic circle of the first order are laid one upon the other, but the lower and the upper one do not touch each other; then these two extremes are in opposite electric states, viz. the extremity which is next to that metallic surface that touches the body of the second class, is positive, and the opposite extremity is negative. Thus let copper, zinc, and moistened leather, be laid one upon the other, as in fig. 12, and the upper end W, viz. the wetted leather, will be found possessed of positive electricity; whilst the lower end C, or the copper, will be found negative.

5. The galvanic effects may be increased to almost any degree, by connecting several of the above-mentioned active combinations, or by a repetition of the same simple galvanic combination (the most active simple combinations forming the most powerful batteries, and vice versa) provided the simple combinations are disposed so as not to contract each other.

Those batteries are said to be of the first or of the second order, according as the simple combinations, of which they consist, are of the first or of the second order. Thus, if a piece of zinc is laid upon a piece of copper, and a piece of moistened card upon the zinc; then a similar arrangement of three other such pieces laid upon them, and a third arrangement upon this, &c. all in the same order; the whole will form a battery of the first order. But if the arrangement is made by connecting a piece of copper with a piece of cloth moistened with water; the latter with a piece of cloth moistened with a solution of sulphuret of potass, and this again with another piece of copper, &c. the whole will form a battery of the second order.

Mr. Davy distinguishes the batteries of the second order into the following three classes:

1. The most feeble is composed, whenever single metallic plates, or arcs, are arranged in such a manner, that two of their surfaces, or ends opposite to each other, are in contact with different fluids, one capable and the other incapable of oxidating the metal. And regular series of such combinations are formed.

2. When the single combinations or elements of the series consist each of a single plate or arc of a metallic substance capable of acting upon sulphureted hydrogen, or upon sulphuret dissolved in water, accompanied with portions of a solution of sulphurets of potass on one side, and water on the other.

3. The most powerful class is formed when metallic substances oxidable in acids, and capable of acting on solutions of sulphurets, are connected, as plates, with oxidating fluids and solutions of sulphuret of potass, in such a maner that the opposite sides of every plate may be undergoing different chemical changes, the mode of alternation being regular.

The above-mentioned restriction, viz. that the parts of a battery must not counteract each other, will be easily understood by considering that every simple, but interrupted galvanic combination, has a positive and a negative end; or that in every complete galvanic circle, the electric fluid circulates in one way only. Thus, if two simple combinations are disposed as in fig. 14, this arrangement will not have any galvanic power, because the actions of the two simple combinations, or the two currents of electricity, are opposed to each other; the two positive ends being called *p*. and the two negative ends *n*. But if those fixed bodies are disposed as in fig. 15, then the combination will be very active; because, according to the hypothesis, the direction of the electric fluid in each simple arrangement tends the same way, and probably the one accelerates the other.

What has been said above of the arrangement of two simple galvanic combinations, must be likewise understood to hold good with respect to the connection of any number of the same; viz. that they must not counteract each other; or, if a certain number of them counteract each other, then the remaining only form the active part of the battery. For instance, if a battery consists of 40 simple combinations, and if 12 of them are placed in a direction contrary to the others; then these 12 will counteract 12 others, and of course the whole battery will have no more power than if it consisted of 16 simple combinations properly disposed.

This points out a method of comparing the powers of two batteries; for if those batteries are connected in an inverted order, viz. the positive end of one to touch the negative end of the other; then, on connecting the two other extremities, or on applying them to proper instruments, the whole power will be annihilated, if the separate batteries had equal power; otherwise the power of the whole will be the excess of the power of the most powerful battery above that of the weakest; and the direction, viz. its being positive or negative, will show to which battery it belongs. It must be observed, with respect to the inactive arrangement of fig. 14, that if one of the separate bodies Z, is removed, then the remaining five bodies will form an active combination; for in that case, W, W, become one body, and S, S, likewise act as one body.

It is almost superfluous to observe, that (as has been said with respect to simple circles) in a galvanic battery the interposition of conductors that have no particular action, or of the conductors of the same class as the adjoining bodies, does not alter the effect of the battery.

Thus far we have stated the general laws, which have been pretty well ascertained with respect to galvanic combinations. We shall now proceed to describe the practical construction, and the effects of those combinations, especially of the compound arrangements or batteries.

The simplicity of single galvanic circles is so great, that nothing more need be said with respect to their construction; for when the three bodies are selected, the operator needs only take care that their contact is perfect.

Galvanic batteries have been constructed of various shapes, and they may be endlessly diversified. But the most useful forms are represented by figs. 16, 17, and 19. Those of figs. 16 and 17 are more easily constructed; that of fig. 16, however, is the most commodious.

The battery, fig. 16, consists of several glasses, or china cups, full of water, or of water containing salt, &c.; and two plates unconnected with each other, viz. a

plate of zinc and a plate of silver, are plunged in the fluid of each cup, excepting the first and last cups; but each of those plates must have a sort of tail or prolongation, by which they are so connected that the silver plate of one cup communicates with the zinc plate of the next, and so on.

The battery, fig. 17, consists of pieces of silver, about as big as half-crowns, pieces of zinc, of an equal size to those of silver, and pieces of card, or cloth, or leather, or other bibulous substance, a little smaller in diameter than the metallic pieces, and soaked in water or in other proper fluid.

Those pieces are disposed in the order of silver, zinc, and wet cloth, &c. as indicated by the letters S, Z, W. The pieces of card, or cloth, must be well soaked in the fluid; but before they are applied, they should be squeezed, in order that the superfluous fluid may not run down the outside of the pile, or insinuate itself between the contiguous pieces of silver and zinc. Those pieces, especially if soaked in plain water, lose their moisture pretty soon, so that they can hardly serve longer than for a day or two; after which time the pile must be decomposed, the metallic pieces cleaned, those of cloth or card soaked again, and the whole arranged as before.

The three rods R, R, R, are of glass or of baked wood; and the piece of wood, O, slides freely up or down the rods. This serves to prevent the falling of the pieces.

When such battery is to be very powerful, viz. is to consist of numerous pieces, the best way is to form two or three or more piles, and to join them by pieces of metal, as *c c* in fig. 18, where two piles are joined together, so that *a* is the negative extremity, and *b* is the other or positive extremity of the whole arrangement, or of the two piles considered as one.

The battery, fig. 19, consists of a strong oblong vessel of baked wood, about three inches deep and about as much broad. In the sides of this vessel grooves are made opposite to each other, and about one-eighth of an inch in depth. In each pair of opposite grooves a double metallic plate, viz. a plate of zinc and a plate of silver soldered together at their edges, are cemented; by which means the wooden vessel is divided into several partitions, or cells, about half an inch broad, as is sufficiently indicated by the figure. The cementation of the metallic pieces into the sides and the bottom of the wooden vessel, must be so accurate as not to permit the passage of any fluid from one cell into the next. The cement proper for this purpose is made by melting together 5 parts of resin, 4 parts of bees'-wax, and 2 parts of powdered red ochre.

Those cells are afterwards filled almost to the top with water, or any other fluid, according to the foregoing table; and thus the whole will form a battery, consisting of various repetitions of silver, zinc, and fluid. Two or more of such batteries may be joined, as has been said of the preceding battery. See fig. 24.

It need hardly be observed, that instead of zinc, copper, and water, other combinations may be made according to the table. At present the last-described batteries are constructed with copper, zinc, and water mixed with a small proportion of nitric or muriatic acid. For the construction of such batteries it is immaterial whether the metals are quite pure or slightly alloyed.

The action of all these batteries is greatest when they are first completed or filled with the fluid; and it declines in proportion as the metal is oxidated, or the fluid loses its power. Hence, after a certain time, not only the fluid must be changed, but the metallic pieces must be cleaned by removing the oxidated surface; which is done either by filing or by rubbing them with sand or sand-paper, or by immersing them for a short time in diluted muriatic acid, and then wiping them with a coarse cloth. The metallic pieces of the battery, fig. 19, may be cleaned by the last method, and may be wiped by introducing a stick with a rag into the cells.

Thus much may be sufficient with respect to the construction of simple and compound galvanic arrangements. It is now necessary to state the effects of those combinations. Indeed, the mode of applying single galvanic circles, and their principal effects, have already been described; yet, for the sake of assisting the memory, it will be useful to collect those effects under the four following heads, in explanation of which we shall add such farther experiments and observations as could not with propriety be mentioned before.

(1) The action of a single galvanic circle affects the organs of living animals, or of animals recently dead, especially when one end of the combination is connected with a nerve, and the other end is connected with a muscle of the same limb.

(2) That action may be transmitted through good conductors of electricity, but not through electrics, or through less perfect conductors.

(3) It affects the electrometer by the intermediation of other instruments.

(4) That action increases, or otherwise modifies, the chemical agency of the bodies concerned, upon each other.

The limbs of animals, especially of frogs recently dead, are the most sensible instruments of galvanic powers; and, in fact, the simplest galvanic circles will affect them, when they will not produce any other decisive electrical effect.

The various powers of different simple circles may be ascertained by applying them to such animal preparations as have their vitality or irritability more or less exhausted. Thus Mr. Volta, in his letter to Gren, says, "If you take a frog, the head of which has been cut off, and which has been deprived of all life by thrusting a needle into the spinal marrow, and immerse it without skinning, taking out the bowels, or any other preparation, into two glasses of water, the rump into one, and the legs into the other as usual; it will be strongly agitated and violently convulsed when you connect the water in both glasses by a bow formed of very different metals, such as silver and lead, or, what is better, silver and zinc; but this will by no means be the case when the two metals are less different in regard to their powers, such as gold and silver, silver and copper, copper and iron, tin and lead. But what is more, the effect will be fully produced on this so little prepared frog, when you immerse in one of the two glasses the end of a bow merely of tin or zinc, and into the other glass the other end of this bow which has been rubbed over with a little alkali. You may perform the experiment still better with an iron bow, one end of which has been covered

with a drop of thin coating of nitrous acid; and beyond all expectation, when you take a silver bow, having a little sulphuret of potass adhering to its extremity."

When a single powerful galvanic combination of the second order is applied with one end to the tongue, and with the other fluid end to some other sensible part of the body, an acid taste is perceived on the tongue, which taste, by continuing the contact. becomes less distinct, and is even changed into an alkaline taste.

If a tin bason is filled with soap-suds, lime-water, or a strong ley, which is still better; and if you then lay hold of the bason with both your hands, having first moistened them with pure water. and apply the tip of your tongue to the fluid in the bason, you will immediately be sensible of an acid taste upon your tongue, which is in contact with the alkaline liquor. This taste is very perceptible, and, for the moment, pretty strong; but it is changed afterwards into a different one, less acid, but more saline and pungent, until at last it becomes alkaline and sharp, in proportion as the fluid acts more upon the tongue.

Mr. Davy observes, that if zinc and silver are made to form a circle with distilled water, holding in solution air, for many weeks, a considerable oxidation of the zinc is perceived, without the perceptible evolution of gas; and the water, at its point of contact with the silver, becomes possessed of the power of tinging green, red cabbage juice, and of rendering turbid, solution of muriate of magnesia.

The chemical action of bodies upon each other is increased by the galvanic arrangement so much, that some of them are by that means enabled to act upon bodies that otherwise they would have no action upon. Fig. 20. represents a glass tube about four inches long. Two corks are thrust into its apertures A and B. An oblong piece of zinc, CD, is fixed into one of the corks, and is made to project within and without the tube. EFG is a silver wire, which, being fixed into the other cork, projects with the extremity E within the tube; and its other extremity is bent so as to come near the projecting part of the zinc C.

Remove one of those corks, and fill the tube with water, in which you must mix a drop or two of muriatic acid; then replace the cork, and you will find that the zinc is acted upon by the diluted acid, is oxidated by it, and bubbles of gas are evolved from it; but the silver wire E remains untouched, and no gass whatever is evolved from it. Now, if you bend the silver wire FG, so that its end G may touch the zinc at C, then the galvanic circle of silver, zinc, and diluted acid is completed, in consequence of which the diluted acid is enabled to act stronger upon the zinc D, which is manifested by the more copious evolution of gas, and is besides enabled to act upon the silver wire; for now you will observe the evolution of gas from the siver E also. Break the contact between G and C, and the silver E will cease to yield gas. Form it again, and gas will again proceed from the silver.

Instead of silver, zinc, and diluted muriatic acid, you may in the same manner use gold, tin, and diluted nitric acid; and by completing the circle, the acid will be enabled to act upon the gold.

It has been observed, that whenever an oxidating influence is exerted at one of the places of contact of the perfect and imperfect conductors, a deoxidating action appears to be produced at the other place. Thus when iron, which oxidates rapidly when forming a circle with silver and common water, is arranged with zinc and common water, it remains perfectly unaltered, whilst the zinc is rapidly acted upon.

Such are the facts which have as yet been discovered with respect to the power of single galvanic circles. They form a remarkable addition to the science of electricity, and open a vast field of speculation and experimental investigation; yet we are unable to form a theory sufficient to account for the original cause, or for the action of that very remarkable power; and we can only wait with patience for the probable elucidation, which may be afforded by farther discoveries.

If the effects of single circles are very remarkable, the collected power of several single circles, or of the battery, cannot fail of surprising the least reflecting mind.

The battery not only convulses the prepared limbs of a frog, or produces the appearance of a flash of light before the human eye; but it shows all the phenomena of electricity in a very considerable degree. It gives the shock; it affects the electrometer; shows a luminous spark, accompanied with an audible report; it burns metallic and other combustible bodies; and continues in action for a very long time, viz. until the chemical action between the component parts of the battery is quite exhausted. The following paragraphs contain a more particular, yet concise, enumeration of these wonderful effects.

When the galvanic battery of the first order consists of 20 repetitions of simple combinations, if you touch with one hand one extremity of the battery, as at *b*, in any one of the above described batteries (See figs. 17, 18, 19), and apply your other hand to the other extremity of the battery, as at *a*, you will feel a very slight shock, like that which is communicated by a Leyden phial weakly charged, and it will be hardly felt beyond the fingers, or at most the wrists. This shock is felt as often as you renew the contact. If you continue the hands in contact with the extremities *b* and *a*, you will perceive a slight but continued irritation; and, when the hand or other part of the body, which touches the extremity of the battery, is excoriated or wounded, this sensation is disagreeable and rather painful.

The dry skin of the human body is seldom capable of conducting this shock; therefore the touching fingers should be well moistened with water. It will be better to immerse a wire that proceeds from one extremity of the battery, in a bason of water, wherein you may plunge one of your hands; then grasping with your other hand well moistened a large piece of metal, for instance a large silver spoon, touch the other end of the battery with it, and the shock will be felt more distinctly. By this means the shock has been felt when the battery consisted of less than twenty repetitions.

Instead of one person, several persons may join hands (which must be well moistened with water), and on completing the circuit, they will all feel the shock at the same instant. But the strength of the shock is much diminished by its passing through the several persons, or, in general, by passing through less perfect conductors.

The shock from a battery consisting of 50 or 60 repe-

titions of the most active combinations of the first order may be felt as far as the elbows; and the combined force of five or six such batteries will give a shock perhaps much stronger than most men would be willing to receive. The prepared limbs of a frog or other animal are violently convulsed, but soon exhausted of their irritability by the action of a galvanic battery.

This shock is similar to that of a large common electrical battery weakly charged, and not to that of a small Leyden phial fully charged. The difference consists in this, viz. that the latter contains a small quantity of electric fluid highly condensed; hence its discharge will force its way through perhaps an inch of air; whereas the former contains a vast quantity of electricity but little condensed; hence its sparks, viz. its course through the air, is so very short, that the fingers must be brought almost into perfect contact in order to receive the shock; and such is the case with the galvanic battery: for the shock from a very powerful battery of this sort will hardly ever force its way through the air, when the extremities of the circle of communication are more than a fortieth of an inch distant, even when those extremities consist of perfect conductors. In this case a small but very vivid spark is seen at that extremity, accompanied with an audible but not strong report. There is no perceptible difference of appearance between the spark of the positive and that of the negative end of the battery.

If a wire proceeding from one extremity of a pretty strong battery is made to communicate with the inside coating, and a wire, which proceeds from the other extremity of the battery, is made to communicate with the outside coating of a common large jar or electrical battery; the latter will become weakly, but almost instantaneously, charged, in the same manner as if it had been charged by a few turns of a common electrical machine; and with that charge you may either give the shock or affect on electrometer, &c.

In short, every thing conspires to prove that a galvanic battery produces a vast quantity of electric fluid, but which is little condensed; and indeed it would be impossible to suppose that the electric fluid could proceed in a very condensed state from an arrangement of bodies, which, whether more or less, are however all good conductors of electricity; for if the fluid was much condensed at one extremity of the battery, and much rarefied at the other extremity, the condensation would soon be made through the pile itself. Indeed, it is difficult to comprehend how this compensation does not take place in all cases.

Having mentioned above, that the charge of a battery may be communicated to a common electrical battery, it is almost superfluous to observe, that the same may be communicated to a condenser, or to a multiplier, and from it to the electrometer. If the battery consists of 200 repetitions, the electrometer will be affected by the simple contact.

The spark, or the discharge of a galvanic battery, when sent through thin inflammable bodies that are in contact with common or oxygen air, sets them on fire, and consumes them with wonderful activity. It fires gun-powder, hydrogen gas, phosphorus, and other combustibles; it renders red-hot, fuses, and consumes very slender metallic wires and metallic leaves. The mode of applying the power of the battery for such purposes is shown in fig. 21. where AB represents a powerful galvanic battery; ACDF is a wire which communicates with the last plate of the battery at A; BKIHG is another wire which communicates with the last plate at B. DE, HI, are two glass tubes, through which those wires pass, and into which they are fastened sufficiently steady. Those tubes serve to move the wires by; for if the operator applies his fingers to the middlemost parts of those tubes, he may move the wires wherever he pleases, without the fear of receiving a shock. If the two extremities F, G, are brought sufficiently near to each other, the spark will be seen between them. It is between those extremities that the combustible substances, or metalic leaf, &c. is to be placed, in order to be fired or consumed. This figure represents the situation of the wires in the act of inflaming gunpowder. A battery consisting of 200 pairs of metallic plates (viz. copper and zinc, each five inches square) melted 23 inches of very fine iron wire. A platina wire about $\frac{1}{175}$ inch in diameter, was melted into a globule. Fig. 24 is the representation of a compound battery of the same kind, fastened together with iron cramps *a, b, c*.

Under the exhausted receiver of the air pump, the galvanic battery acts less powerfully than in the open air; but in oxygen air it acts with increased power.

The flash of light which appears before the eye of the experimenter, when the eye itself, or some other part not very remote from it, is put in the circuit of a galvanic combination, does not appear much greater when a battery is employed than when two plates are applied in the manner which has been already mentioned; but when the battery is used, the sensation of a flash may be produced in various ways. If one hand or both be placed in perfect contact with one extremity of the battery, and almost any part of the face brought into contact with the other extremity of the battery, the flash will appear very distinctly, the experimenter being in the dark, or keeping his eyes shut. This flash appears very strong, when a wire which proceeds from one extremity of the battery is held between the teeth, and rests upon the tongue, whilst the other wire is held in the hand. In this case the lips and the tongue are convulsed, the flash appears before the eyes, and a very pungent taste is perceived in the mouth.

If any part of the human body, forming part of the circuit of a galvanic battery, is kept sometime in that situation, the irritation or numbness is more or less distinct, and more or less painful, according to the sensibility of the parts concerned. This application is likely to prove most useful as a remedy in various disorders. It is said that it has already proved beneficial in deafnesses and in rheumatisms. It highly deserves to be tried by medical persons. See fig. 25.

The most extraordinary phenomena of a galvanic battery are the chemical effects and the modifications which are produced by it upon the bodies concerned, or upon such as are placed in the circuit. We shall first describe the simplest mode of exhibiting the principal of those phenomena, namely, the evolution of gas from water, from which the mode of conducting similar experiments is easily derived; then shall transcribe the various particulars which relate to those chemical effects, from the

Journals of the British Royal Institution, where they are concisely expressed.

AB, fig. 22, exhibits a glass tube full of distilled water and having a cork at each extremity. EF is a brass or copper wire, which proceeds from one extremity of a galvanic battery, and, passing through the cork A, projects within the tube. HG is a similar wire, which proceeds from the other extremity of the battery, and comes with its extremity G within the distance of about an inch or two from the wire F.

In this situation of things, you will find that bubbles of gas proceed in a constant stream from the surface G of the wire which proceeds from the negative end of the battery; these bubbles of gas, ascending to the upper part of the tube, accumulate by degrees. This gas is the hydrogen, and may be inflamed. At the same time the other wire F deposits a stream of oxide in the form of a stream or cloud, which gradually accumulates in a greenish form in the water, or on the sides of the tube, and is a perfect oxide of the brass. The wire F is readily discoloured and corroded. If you interrupt the circuit, the production of gas and of oxide ceases immediately. Complete the circuit, and the production of gas re-appears.

This production of gas may be observed even where the battery consists of not more than six or eight repetitions of silver, zinc, and water. In short, if the power of the battery is sufficient to oxidate one of the wires of communication, the other wire will afford hydrogen gas; both extremities of the wires being in water.

In this experiment it seems that the hydrogen is separated from the water, and is converted into a gaseous state by the wire connected with the negative extremity of the battery; whilst the oxygen unites with and oxidates the wire connected with the positive end of the battery. If you connect the positive end of the battery with the lower wire of the tube, and the negative with the upper, then the hydrogen proceeds from the upper wire, and the lower wire is oxidated.

If the two wires of gold or platinum are used, which are not oxidable; then the stream of gas issues from each, the water is diminished, and the collected gas is found to be a mixture of hydrogen and oxygen. It explodes violently.

Those two different elastic fluids may be obtained separate from each other by the following means: Let the extremities of the two wires which proceed from the battery, be immersed in water, at the distance of about an inch from each other, and place over each of them a small glass vessel inverted and full of water, as in fig. 23. Dr. Priestley, however, who denies the convertibility of water into hydrogen and oxygen air, thinks that the elastic fluid in these experiments originates from the air which is contained in the water; "since," says he, "if by means of oil upon the water, or a vacuum, access to the atmosphere is cut off, the whole production of gas ceases." Nor is any air produced when the water has been exhausted of it.

In the above described apparatus, a little hole must be made in the lower cork B, for the purpose of giving exit to the water in proportion as the gas is formed.

In all batteries of the first order, when the connexion is completed, changes take place which denote the evolution of influences capable of producing from common water oxygen and hydrogen, acid and alkali, in different parts of the body.

Thus in the battery with a series of zinc plates, silver wires, and common water, oxide of zinc is formed on all the plates of zinc, whilst hydrogen is produced from the silver wires; and if the water in contact with them is tinged with red cabbage juice, it becomes green.

And in the battery with silver, gold, and weak nitric acid, the silver is dissolved, whilst the acid becomes green, and slowly evolves gas at its points of contact with the gold.

The chemical agencies exerted in the compound batteries of the first order can be best observed by the substitution of single metallic wires for some of the plates; for, in this case, the changes taking place in the series with wires, will be exactly analogous to those produced in the series with plates; silver, and all the more oxidable metals, oxidating in water, in the usual place, and gold and platina evolving oxygen gas.

Thus, when in two small glass tubes, connected by a moist animal substance, and filled with distilled water, two gold wires are introduced from a large battery in the proper order, oxygen is produced in one quantity of water, and hydrogen in the other, nearly in the proportions in which they are required to form water by combustion: and if the process is continued for some time, the apparatus being exposed to the atmosphere, the water, in the oxygen-giving tube, will become impregnated with an acid (apparently the nitrous); whilst that in the hydrogen-giving tube will be found to hold in solution an alkali, which, in certain cases, has appeared to be fixed.

From some experiments it would appear probable, that the quantities of hydrogen, produced in series, are small, and the quantities of alkali great, in proportion as the surfaces of contact of the least oxidable metals with the water are more extended.

All the oxygenated solutions of bodies possessing less affinity for oxygen than nascent hydrogen, are decomposed when exposed to the action of the metal occupying the place of the least oxidable part of the series in the compound circle.

Thus, sulphur may be produced from sulphuric acid; and copper and other metals precipitated in the metallic form from their solvents.

It is well known that hydrogen gas, in its nascent state, reduces the oxides of metals. Accordingly, when the tube. fig. 22. is filled with a solution of acetite of lead in distilled water, and a communication is made with the battery as above described, no gas is perceived to issue from the wire which proceeds from the negative end of the battery; but, in a few minutes, beautiful metallic needles are perceived on the extremity of this wire; these soon increase. and assume the form of a fern or other vegetable. The lead thus separated is in its perfect metallic state, and very brilliant.

When a solution of sulphat of copper is employed, the copper is precipitated in its metallic state; but instead of appearing in crystals, it forms a kind of button, which adheres firmly to the end of the wire.

On making the experiment with a solution of nitrate of silver, the silver is precipitated in the form of a beautiful metallic brush, the metal shooting into fine needle-like crystals.

If iron is immersed in a solution of sulphate of copper, the latter metal will be precipitated in a metallic form, and will adhere to the surface of the former. Upon silver merely immersed in the same solution, no such effect is produced; but as soon as the two metals, viz. the silver and the copper, are brought into contact, the silver receives a coating of copper.

Little knowledge has yet been obtained concerning the chemical changes taking place in the batteries of the second order. But from several experiments it would appear that they are materially different in the laws of their production from those taking place in the first order.

Thus, when single metallic wires with water are placed as series in powerful batteries of the second order, the influence producing oxygen seems to be transmitted by the point in the place of that part of the plate which was apparently incapable of undergoing oxidation; whilst the hydrogen is evolved from that point where the oxidating part of the primary series appeared to exist.

The agency of the galvanic influence, which occasions chemical changes and communicates electrical charges, is probably in some measure distinct from that agency which produces sparks and the combustion of bodies.

The one appears (all other circumstances being similar) to have little relation to surface in compound circles, but to be great in some unknown proportion, as the number of series are numerous. The intensity of the other seems to be as much connected with the extension of the surfaces of the series as with their number.

Thus, though eight series composed of plates of zinc and copper, about 10 inches square, and of cloths of the same size, moistened in diluted muriatic acid, give sparks so vivid as to burn iron wire, yet the shocks they produce are hardly sensible, and the chemical changes indistinct; whilst 24 series of similar plates and cloths, about two inches square, which occasion shocks and chemical agencies more than three times as intense, produce no light whatever.

A measure of the intensity of the power in galvanic batteries, producing chemical changes, may be derived from the quantity of gas it is capable of evolving from water in a given time.

The preceding facts can hardly leave any doubt with respect to the identity of the galvanic power and the electricity which is produced by means of a common electrical machine, or that is brought down from the clouds; but, what is still more remarkable, it reconciles to the same principle the animal electricity, viz. the power of the torpedo, gymnotus electricus, &c. since all the phenomena of the animal electricity agree with those of the galvanic battery. See ELECTRICITY.

But the most striking circumstance is, that the electric organ of any of the above-mentioned fishes seems to be constructed exactly like a galvanic battery; for it consists of little laminæ or pellicles arranged in columns, and separated by moisture. It seems, in short, to be a galvanic battery, consisting of conductors of the second order only, but undoubtedly of different conducting powers.

Though the galvanic battery exhibits all the leading properties of common electricity, such as the attraction, the spark, &c. yet in some effects, viz. the decomposition of water, oxygenation of metals, &c. the former seem to differ considerably from the latter; but those apparent differences have been sufficiently reconciled by some very ingenious experiments and observations of Dr. W. H. Wollaston. See Phil. Trans. 1801.

With respect to the decomposition of water, which was thought to require very powerful electrical machines, he justly suspected, that by reducing the surface of communication, the decomposition of water might be effected with less powerful means; and this was verified by actual experiments. "Having," he says, "procured a small wire of fine gold, and given it as fine a point as I could, I inserted it into a capillary glass tube; and after beating the tube so as to make it adhere to the point, and cover it in every part, I gradually ground it down, till, with a pocket-lens, I could discern that the point of the gold was exposed.

"The success of this method exceeding my expectations, I coated several wires in the same manner, and found that when sparks from the conductors were made to pass through water by means of a point so guarded, a spark passing to the distance of one-eighth of an inch would decompose water, when the point exposed did not exceed $\frac{1}{700}$ of an inch in diameter. With another point which I estimated at $\frac{1}{1500}$ of an inch, a succession of of sparks, $\frac{1}{20}$ of an inch in length, afforded a current of small bubbles of air.

"I have since found that the same apparatus will decompose water with a wire $\frac{1}{40}$ of an inch diameter, coated in the manner before described, if the spark from the prime conductor passes to the distance of $\frac{4}{10}$ of an inch of air."

He also found that with a gold point similar to, but much smaller than any of the above-mentioned, and similarly situated in water, the mere current of electricity, without any sparks, would occasion a stream of very small bubbles to rise from the extremity of the gold.

"Having coloured a card," he adds, "with a strong infusion of litmus, I passed a current of electric sparks along it, by means of two fine gold points, touching it at the distance of an inch from each other. The effect, as in other cases, depending on the smallness of the quantity of water, was most discernible when the card was nearly dry. In this state, a very few turns of the machine were sufficient to occasion a redness at the positive wire, very manifest to the naked eye. The negative wire being afterwards placed on the same spot, soon restored it to its original blue colour."

Dr. Wollaston likewise remarks another strong point of analogy between the electricity of the galvanic battery and that of a common electrical machine, viz. that they both seem to depend upon oxidation. In fact, a common electrical machine will act more or less powerfully, according as the amalgam which is applied to its rubber consists of metals that are more or less oxidable.

GAMBEZON, or GAMBA, in antiquity, a kind of soft quilted waistcoat, worn under the coat of mail to prevent its hurting the body. It was made of wool or cotton, quilted between two stuffs, and was also called counterpoint.

GAMBOGE, is a concreted vegetable juice, and is partly of a gummy and partly of a resinous nature. It

is brought to us either in form of orbicular masses, or of cylindrical rolls of various sizes, and is of a dense, compact, and firm texture, and of a beautiful yellow. It is chiefly brought to us from Cambaja, in the East Indies, called also Cambodja and Cambogia; and thence it has obtained its names of cambadium, cambogium, and gambogium.

It is a very rough and strong purge; it operates both by vomit and stool, and both ways with much violence, almost in the instant in which it is swallowed, but yet without griping. It requires caution and judgment in administering it; but those who know how to give it properly, find it an excellent remedy in dropsies, cachexies, jaundice, asthmas, catarrhs, and in the worst cutaneous eruptions.

Its dose is from two or three grains to six, eight, or ten: four grains generally operate briskly without vomiting, and eight or ten grains usually vomit briskly, and afterwards purge downwards.

It is at present much more esteemed by painters in water-colours than by physicians.

GAME, in general, signifies any diversion or sport that is performed with regularity, and restrained to certain rules.

Games are usually distinguished into those of address and those of hazard. To the first belong chess, tennis, billiards, wrestling, &c. and to the latter those performed with cards or dice, as back-gammon, ombre, picquet, whist, &c.

It would be a most salutary maxim to be adopted generally, that no game should be pursued but such as afforded exercise, and consequently contributed to the health of the body. In this view we greatly prefer such as tennis and billiards to the pernicious sedentary games at present pursued, which are only productive of gouts, palsies, &c.

Games, in antiquity, were public diversions, exhibited on solemn occasions. Such, among the Greeks, were the Olympic, Pythian, Isthmian, Nemæan, &c. games; and, among the Romans, the Apollinarian, Circensian, Capitoline, &c. games.

It was also customary among the Greeks for persons of quality to institute games, with all sorts of exercises, as running, wrestling, boxing, &c. at the funerals of their friends, to do them honour, and render their death more remarkable. This practice is frequently mentioned by ancient writers, as Miltiades's funeral in Herodotus, Brasidas's in Thucydides, Timoleon's in Plutarch, with many more. Nor was this custom peculiar to later ages, since we find the description of Patrocius's funeral games takes up the greatest part of one of Homer's Iliads; and even prior to this, the funeral of Œdipus is said to have been solemnized with sports.

Among the Romans, there were three sorts of games, viz. sacred, honorary, and ludicrous. The first were instituted immediately in honour of some deity or hero; of which kind were those already mentioned, together with the augustales, florales, palatini, &c. The second class were those exhibited by private persons at their own expense, in order to please the people, and ingratiate themselves with them, to make way for their own preferment: such were the combats of gladiators, the scenic games, and other amphitheatrical sports. The ludicrous games were much of the same nature with the games of exercise and hazard among us: such were the ludus trojanus, tesseræ, tali, trochus, &c.

By a decree of the Roman senate, it was enacted, that the public games should be consecrated and united with the worship of the gods; whence it appears, that feasts, sacrifices, and games, made up the greatest part, or rather the whole, of the external worship offered by the Romans to their deities. Others distinguish the Roman games into

1. The equestrian, or curule games, which were the same with the circensian. 2. The gymnic games, wherein were exhibited gladiatorial and other shows of the like nature: these were sacred to Mars and Minerva. 3. The theatrical entertainments, consisting of tragedies, comedies, &c.; these were sacred to Apollo, Bacchus, Minerva, Venus, &c.

Game. It is a maxim of the common law of England, that goods of which no person can claim any property belong to the king by his prerogative. Hence those animals feræ naturæ, which come under the denomination of game, are styled in our laws his majesty's game; and that which he has he may grant to another; in consequence of which another may prescribe to have the same, within such a precinct or lordship. And hence originated the right of lords of manors or others to the game within their respective liberties.

As the sole right of taking and destroying game belongs exclusively to the king, as such he may authorize the only persons who can acquire any property, however fugitive and transitory, in the animals coming under that denomination.

For the preservation of these species of animals; for the recreation and amusement of persons of fortune, to whom the king, with the advice and assent of parliament, has granted the same; and to prevent persons of inferior rank from misemploying their time, the following acts of parliament have been made. The common people are not injured by these restrictions, no right being taken from them which they ever enjoyed; but privileges are granted to those who have certain qualifications therein mentioned, which before rested solely in the king. 2 Bac. Abr. 612.

For the sake of perspicuity, we have arranged the different acts of parliament in alphabetical order.

Certificates to be dated the day of the month when issued, and shall be in force till the 1st of July following and no longer: and if any clerk of the peace, his deputy or steward, clerk, &c. issue certificates otherwise than directed, to forfeit 20*l*. 25 G. III. sess. 2.

No person to destroy game until he has delivered an account of his name and place of abode to the clerk of the peace, or his deputy, or to the sheriff or steward clerk of the county, riding, shire, stewartry, or place where such person shall reside, and annually take out a certificate thereof, which must have a stamp duty of 3*l*. 3*s*. 25 Geo. III. sess. 2.

Any person counterfeiting or forging any seal or stamp directed to be used by this act, with intent to defraud the revenue, or shall utter and sell such counterfeit, on conviction thereof shall be adjudged a felon, and shall suffer death without benefit of clergy; and all provisions of

former acts relative to stamp duties to be in force in executing this act. *Id.*

Every qualified person shooting at, killing, taking, or shooting any pheasant, partridge, heath-fowl, or black-game, or any grouse or red game, or any other game, or killing, taking or destroying any hare with any greyhound, hound, pointer, spaniel, setting-dog, or other dog, without having obtained such certificate, shall forfeit the sum of 20*l.* *Id.*

Clerks of the peace or their deputies, or the sheriff or steward clerks, in their respective counties, ridings, shires, stewartries, or places, shall, on or before November 1, 1785, or sooner if required by the commissioners of his majesty's stamp duties, transmit to the head office of stamps in London, a correct list in alphabetical order of the certificates by them issued between the 25th day of March, in the year 1785, and the 1st of October in the same year; and shall also in every subsequent year, on or before the 1st of August in each year, make out and transmit to the stamp-office in London, correct alphabetical lists of the certificates so granted by them, distinguishing the duties paid on each respective certificate so issued; and on delivery thereof, the receiver-general of the stamp duties shall pay to the clerk of the peace, &c. for the same one-halfpenny a name; and in case of neglect or refusal, or not inserting a full, true, and perfect account, he shall forfeit 20*l.* *Id.*

Lists may be inspected at the stamp-office for 1*s.* each search; *id.* which lists shall once or oftener in every year, be inserted in the newspapers in each respective county.

If any qualified person, or one having a deputation, shall be found in pursuit of game, with gun, dog, or net, or other engine for the destruction of game, or taking or killing thereof, and shall be required to show his certificate by the lord or lady of the manor, or proprietor of the land whereon such person shall be using such gun, &c. or by any duly-appointed game-keeper, or by any qualified or certified person, or by any officer of the stamps, properly authorized by the commissioners, he shall produce his certificate; and if such person shall refuse, upon the production of the certificate of the person requiring the same, to show the certificate granted to him for the like purpose; or in case of not having such certificate to produce, shall refuse to tell his christian and surname, and his place of residence, and the name of the county where his certificate was issued, or shall give in any false or fictitious name, he shall forfeit 50*l.* *Id.*

Certificates do not authorize any person to shoot at, kill, take or destroy any game at any time that is prohibited by law, nor give any person a right to shoot at, &c. unless he is duly qualified by law. *Id.*

No certificate obtained under any deputation shall be pleaded or given in evidence, where any person shall shoot at, &c. any game out of the manors or lands for which it was given. The royal family are exempted from taking out certificates for themselves or their deputies. *Id.*

Conies.—Destroying conies, transportation. 5 G. III. c. 14.

Robbing warrens, felony without clergy. 9 G. I. s. 22.

Killing them in the night, or endeavouring to kill them, fine of 10*s.* or commitment. 22 and 23 Car. II. c. 25.

Unqualified person using a gun to kill them, the same may be seized. 3 Jac. I. c. 13.

Deer.—Stalking deer without leave, 10*l.* 19 H. VII. c. 11.

Hunting or killing them, 10*l.*, costs, and sureties for good behaviour. 5 Eliz. c. 21.

Buck stalls or engines kept by unqualified persons may be seized. 3 Jac. I. c. 13.

Selling or buying them to sell again, 40*l.* 3 Jac. I. c. 27.

Coursing or killing them without consent, 20*l.* 13 Car. II. c. 10.

Hunting, taking, killing, or wounding, 30*l.* or transportation. 3 W. III. c. 10.; 5 G. I. c. 15.; 9 G. I. c. 22.; 10 G. II. c. 32.

Destroying pales or walls of inclosed grounds, without consent, 30*l.* 5 G. I. c. 15.

Keeper of parks privately killing or taking them, 50*l.* *Id.*

Robbing places where kept, felony without clergy. 9 G. I. c. 22.

Game-keepers.—All lords of manors, or other royalties, may appoint game-keepers, and empower them to kill game. 22 and 23 Car. II. c. 25.

But if game-keepers dispose of the game without the lord's consent, he shall be committed for three months, and kept to hard labour. 5 Anne, c. 14.

But no lord shall make above one game-keeper within one manor, with power to kill game, and his name shall be entered with the clerk of the peace; certificate whereof shall be granted by the clerk of the peace on payment of 10*s.* 6*d.* Unqualified game-keeper killing or selling hare, pheasant, partridge, moor, heath-game, or grouse, he shall forfeit 5*l.* by distress, or commitment for three months for the first offence, and every other four. 9 Anne, c. 21.

No lord shall appoint an unqualified game-keeper, or one who is not bona fide servant to such lord, or immediately employed and appointed to take and kill game for the use of the lord; other persons, under colour of authority for taking and killing game, or keeping any dogs or engines whatsoever for that purpose, shall forfeit 5*l.* in like manner. 3 G. I. c. 11.

Every deputation of a game-keeper to be registered with the clerk of the peace, or in the sheriff's or steward's court-books of the county, &c. where the lands lie, and annually take out certificate thereof, stamped with a half-guinea stamp (now 1*l.* 1*s.*). 25 Geo. III. sess. 2.

Every game-keeper, from and after the passing of this act, who shall deliver his name and place of abode as aforesaid, and require a certificate, shall be annually entitled thereto, stamped as before directed, from the clerk of the peace or his deputy, sheriff or steward, clerk, &c. to the effect of the form in the act set forth. *Id.*

Clerk of the peace, &c. after signing certificate, shall issue the same stamped, to the person registering the deputation, on requiring the same, for which he may receive 1*s.* *Id.*

If any person to whom any deputation or appointment of a game-keeper shall have been, or at any time thereafter shall be, granted, by any lord or lady of a manor, &c. shall, for the space of 20 days after the de-

putation or appointment shall be granted, neglect or refuse to register the same, and take out a certificate as aforesaid, he shall forfeit and pay the sum of 20*l.* to be applied as the law directs. *Id.*

Neglect or refusal of issuing certificates, incurs a forfeiture of 20*l.* recoverable in the courts of Westminster, court of session, of justiciary, or exchequer in Scotland, by action of debt or information, for the use of the plaintiff, with double costs of suit. *Id.*

Clerk of the peace, &c. may issue his certificate to any game-keeper first appointed in any year after 1st of July in that year. *Id.*

If any lord or lady of a manor, or proprietor of land, shall make any new appointment of a game-keeper, and shall register the deputation with the clerk of the peace, &c. and shall obtain a new certificate thereon, the first shall be void; and any person acting under the same, after notice, shall be liable to all the penalties of the game-laws, and those against unqualified persons. *Id.*

Hares.—Every person tracing or coursing hares in the snow shall be committed for one year (31 Eliz. c. 5.), unless he pay to the churchwardens, for the use of the poor, 20*s.* for every hare, or become bound by recognizances, with two sureties in 20*l.* apiece, not to offend again; and every person taking or destroying hares with any sort of engine, shall forfeit for every hare 20*s.* in like manner. 1 Jac. I. c. 27. Persons found using engines, liable to the punishment inflicted as above, by 31 Eliz. c. 5. Unqualified persons keeping or using sporting-dogs, or engines to kill or destroy hares, shall forfeit 5*l.* to the informer, with double costs (2 Geo. III. c. 19.), by distress, or be committed for three months for the first offence, and for every other four. 5 Anne, c. 14. Taking or killing hares in the night-time, forfeits 5*l.* (9 Anne, c. 25.), the whole to the informer, with double costs. 2 Geo. III. c. 19. Killing or taking with gun, dog, or engine, a hare in the night, between the hours of seven at night and six the morning, from October 12 to February 12, and between the hours of nine at night and four in the morning, from Feb. 12, to Oct. 12, or in the day-time upon Sunday or Christmas-day, to forfeit not less than 10*l.* nor more than 20*l.* for the first offence; nor less than 20*l.* nor more than 30*l.* for the second offence; and 50*l.* for the third offence, with costs and charges; and, upon neglect or refusal, be committed for six or twelve calender months, and may be publicly whipped; final appeal to the quarter-sessions. 13 Geo. III. c. 80. Persons armed and disguised stealing them, felony without clergy. Geo. I. c. 22. Higler, chapman, carrier, inn-keeper, victualler, or alehouse-keeper, having in his custody, or buying, selling, or offering to sale, any hare, unless sent up by some person qualified (or any person selling, exposing, or offering for sale hares, &c. 28 Geo. II. c. 22.) shall forfeit for every hare 5*l.*, the whole to the informer. 2 Geo. III. c. 92.

Heath-fowl.—For preserving heath-cocks or polts, no person whatsoever, on any waste, shall presume to burn, between Feb. 2 and June 24, any grig, ling, heath, furze, goss, or fern, on pain of commitment for a month or ten days, to be whipped and kept to hard labour. 4 and 5 W. and M. c. 23. Shooting heath-cocks, grouse, or moor-game, contrary to 1 Jac. I. c. 27. and killing any of them in the night, or using gun, dog, or engine, with such intent, contrary to 9 Anne, c. 25. and 13 Geo. III. c. 80.; and carriers and others having such in their possession, contrary to 9 Anne, c. 14. are all liable to the same penalties, and recoverable in the same manner, as those offences are subjected to shooting, &c. hares.

Partridges.—Taking partridges by nets or other engines, upon another's freehold, without special leave of the owner of the same, penalty 10*l.* half to him who shall sue, and half to the owner or possessioner. 11 H. VIII. c. 17. Shooting, &c. at partridges with gun or bow, or taking them, &c. with dogs or nets, by 7 Jac. I. c. 11. or taking their eggs out of their nest, liable as persons shooting, &c. at hares, and also 20*s.* for every bird or egg. Selling, or buying to sell again, a partridge (except reared and brought up in houses, or from beyond sea), forfeits for every partridge 10*s.* half to him who will sue, and half to the informer. 1 Jac. I. c. 27. Taking, killing, or destroying partridges in the night, forfeits for every partridge 10*l.* half to him who will sue, and half to the lord of the manor, unless he license or cause the said taking or killing, in which case his half shall go to the poor, recoverable by churchwardens; and if not paid in ten days, to be imprisoned for one month; and moreover shall give bond to the justice, with good sureties, not to offend again for two years. 23 Eliz. c. 10. to kill a partridge in the night, penalty 5*l.* 9 Anne, c. 25. The whole whereof is given to the informer (2 Geo. III. c. 19.) and may be recovered within three months (5 Anne, c. 14), before a justice of peace, or within six months, by action in the courts of record at Westminster (9 Anne, c. 25.) with double costs. 2 Geo III. c. 19. Keeping or using any greyhounds, setting dogs, or any engine for destroying partridges, penalty 5*l.* to be levied and recovered as the like penalty for killing hares. Penalties for using gun, dog, snare, net, or other engine, with intent to take or destroy partridges in the night, or on Sunday, or Christmas-day, same as using them against hares, by 13 G. III. c. 80. Carriers and others having partridges in their possession, liable to the same forfeitures and penalties as having hares; and the same law against shooting them by unqualified persons as for killing hares.

Pheasants.—All the laws respecting the penalties and recovery of them, for taking them by nets, snares, or other engines, without license of the owner, by 11 H. VIII. c. 17. and for shooting or destroying them with dogs or snares, &c. by 7 Jac. I. c. 11. or taking their eggs, by 1 Jac. I. c. 27. and for selling, and buying them to sell again, by last-cited act (except that the penalty for a pheasant is 20*s.*), and for destroying them in the night (except as aforesaid), by 23 Eliz. c. 10. 9 Anne, c. 25. and 13 G. III. c. 80. and for keeping or using sporting-dogs or engines for destroying them on Sunday or Christmas-day, by 13 G. III. c. 80. and for carriers and others having them in their possession. All these laws are, mutatis mutandis, verbatim the same as those respecting partridges.

Prosecutions.—Any one prosecuted for any thing done in pursuance of this act may plead the general issue, and give the special matter in evidence for his defence; and if upon trial verdict pass for the defendant, or plaintiff become nonsuited, defendant shall have treble costs of plaintiff. 25 Geo. III. sess. 2. s. 28.

Qualifications for killing game are, 1. having a freehold estate of 100*l.* per annum, 22 and 23 Car. II. c. 25.; 2. a leasehold estate for 99 years, of 150*l.* per annum; 3. the eldest son or heir apparent to an esquire, or person of superior degree; 4. the owner or keeper of a forest, park, chace, or warren. Unqualified person keeping dogs or engines to destroy game, to forfeit 5*l.* 5 Anne, c. 14.

No person (other than the king's son), unless he has lands of freehold to the value of five marks a year, shall have any game of swans, on pain of forfeiting them, half to the king, and half to any person so qualified, who shall seize the same. 22 Ed. IV. c. 6.

Any gentleman or other that may dispend 40*s.* a year freehold, may hunt and take wild fowls with their spaniels only, without using a net or other engine, except the long bow. 25 Hen. VIII. c. 11. From persons not having land of 40*s.* a year, or not worth in goods 200*l.* using gun or bow to kill deer, any person having 100*l.* may seize the same to his use. 3 Jac. I. c. 13.

Every person qualified to kill game, shall, previous to his shooting at, killing, or destroying any game, take out a certificate. See CERTIFICATE.

Sporting seasons.—The time for sporting in the day is from one hour before sun-rising until one hour after sun-setting. 10 G. III. c. 19.

For bustards, the sporting season is, from December 1 to March 1.

For grouse or red grouse, from August 11 to December 10.

Hares may be killed all the year, under the restriction, as to the hours of the day, in 10 Geo. III. c. 19.

Heath-fowl, or black game, from August 20 to December 20.

Partridges, from September 1 to February 12.

Pheasants, from October 1 to February 1.

Widgeons, wild ducks, wild geese, wild fowls, at any time but in June, July, August, and September.

Summary proceedings.—From and after March 1, 1785, in all cases where the penalty by this act does not exceed 20*l.* a justice of peace shall, upon information or complaint, summon the party and witnesses to appear, and proceed to hear and determine the matter in a summary way; and upon due proof by confession, or upon the oath of one witness, give judgment for the forfeiture, and issue his warrant for levying the same on the offender's goods, and to sell them, if not redeemed within six days, rendering to the party the overplus; and if his goods are insufficient to answer the penalty, shall commit the offender to prison, there to be for six calendar months, unless the penalty is sooner paid; and if the party is aggrieved by the judgment, he may, upon giving security amounting to the value of the forfeitures, with the costs of the affirmance, appeal to the next general quarter-sessions, when it is to be heard and finally determined; and in case the judgment is affirmed, the sessions may award such costs, incurred by the appeal, as to themselves shall seem meet. 25 Geo. III. sess. 2.

Witnesses neglecting or refusing to appear, without reasonable excuse to be allowed of by the justice, shall respectively forfeit for every offence 10*l.* to be levied and paid as other penalties by this act. *Id.*

Justice to cause conviction to be made out to the effect of the form set forth in the act. *Id.*

Justice may mitigate penalties as he thinks fit, so that reasonable costs and charges of the officers and informers for discovery and prosecution be always allowed, over and above mitigation, and so as the same does not reduce the penalties to less than a moiety over and above the costs and charges, any thing therein contained to the contrary notwithstanding; and no such conviction shall be removable by certiorari into any court whatsoever.

No offender against this act to be imprisoned more than three months. *Id.*

The duties to be paid to the receiver-general of the stamp-duties, and by him paid into the exchequer. *Id.*

Swans.—It is felony to take any swans that are lawfully marked, though they should be at large; and so it is unmarked swans, if they are domestic or tame, so long as they keep within a man's manor, or within his private river, or if they happen to escape from them, and are pursued and taken, and brought back again; but if they are abroad, and attain their natural liberty, then the property of them is lost, and so long felony cannot be committed by taking them. Burn's Just. tit. Game.

Wild fowl.—Same laws against shooting wild-fowl as for shooting hares, by 1 Jac. I. c. 27.

GAME-COCK, a fighting-cock, or one kept for sport, in the choice of which four things are chiefly to be regarded, viz. shape, colour, courage, and sharp heel.

1. As to shape, a game-cock must not be chosen either too large or too small: the first being generally unwieldy and inactive; the other weak and tedious in fighting. The middle-sized cock is therefore most proper for this purpose, as being strong, nimble, and easily matched; his head ought to be small, with a quick large eye, and a strong beak, which should be crooked, and in colour suitable to the plume of his feathers; the beam of his leg should be strong, and of the colour of his plume; his spurs should be rough, long, and sharp, a little bending, and pointing inward. 2. The best colour for a game-cock is either grey, yellow, or red; the pyed pile may pass indifferently; but the white and dun are rarely known to be good for any thing. If his neck is invested with a scarlet complexion it is a sign of his being strong, lusty, and courageous; whereas a pale and wan complexion denotes him faint and unhealthy. 3. His courage may be known by his proud, upright standing, and stately tread in walking; and if he crows frequently in the pen, it is a proof of spirit. 4. His sharpness of heel is known only from observations in fighting: that is, when at every rising he hits so that he draws blood from his adversary; gilding his spurs continually, and at every blow threatening him with immediate death.

To prepare a cock to fight: 1. With a pair of fine shears to cut all his mane off, close to his head, from the head to the setting of the shoulders. 2. Clip off all the feathers from the tail close to his rump, and the redder it appears, the better is the cock in condition. 3. Spread his wings by the length of the first rising feather; and cut off the rest slopewise, with sharp points, that in his rising he may therewith endanger an eye of his adversary. 4. See that there be no feathers on the crown of

his head for his opponent to take hold of; and moisten his head all over with your spittle.

GAME-KEEPERS. See GAME.

GAMELION, in ancient chronology, was the eighth month of the Athenian year, containing 29 days, and answering to the latter part of our January and beginning of February. It was thus called, as being, in the opinion of the Athenians, the most proper season of the year for marriage.

GAMING, the art of playing or practising any game, particularly those of hazards as cards, dice, tables, &c. It appears that by the ancient common law all games were lawful. But so early as the reign of Richard II. the legislature found it necessary to interfere, and to make several games illegal. This was levelled at labourers and artificers. The next statute was the 2nd Hen. IV. which inflicted six days imprisonment on those who offended against the act of Richard II. The 17th Edw. IV. imposes a penalty of two years imprisonment and a fine against various games there enumerated; and by the 11th Hen. VII. labourers and artificers are prohibited from playing at unlawful games, but in Christmas only. The principal object of these early statutes was, to encourage archery, and to make that the only lawful sport for the lower ranks of the people. But the earliest act against gaming now in force is the 33d Henry VIII. which gives justices of peace and head officers in corporations a power to enter all houses suspected of unlawful games, and to arrest the gamesters till they give security not to play for the future. Persons keeping any unlawful gaming-house, are fined 40*s.* and the gamesters 6*s.* 8*d.* a time. If any person by fraud, deceit, or unlawful device, in playing either at cards or dice, tables, bowls, cock-fighting, horse-races, &c. or bearing a share in the stakes or betting, shall win any money or valuable thing of another, he shall forfeit treble the value thereof: likewise if any person shall play at any of the said games upon tick, and not for ready money, and lose the sum of 100*l.* on credit, at one meeting, if the money is not paid down, his security taken for it shall be void, and the winner becomes liable to a forfeiture of treble value of such money won. 16 Car. II. c. 7. Not only all notes, bills, bonds, mortgages, or other securities given for money won at gaming, are declared void; but also where lands are granted, they shall go to the next person entitled, after the decease of the person so incumbering the same. Persons losing by gaming at one time 10*l.* may recover the money lost from the winner, by an action of debt brought within three months; and on the loser's not prosecuting, any other person may lawfully do it, and recover treble the value, with costs. 9 Anne, c. 14. Those who cheat at cards, dice, &c. besides their forfeitures, have inflicted on them such infamy and corporal punishment, as in cases of perjury; and beating, or challenging any other person to fight, on account of money won by gaming, shall forfeit all their goods, and be imprisoned two years: and where persons play that have no visible estates, and do not make it appear that the principal part of their maintenance is got by other means than gaming, they may be bound to their good behaviour by two justices of the peace, &c. Stat. ibid. See 2 Geo. II. c. 28. The ace of hearts, pharaoh, basset, &c. are judged to be lotteries by cards or dice; and persons who set up those games, are subject to 200*l.* penalty. And every adventurer, who shall play, stake, or punt at them, forfeits 50*l.* Also any sales of houses, goods, plate, &c. in such a way, are void, and the things forfeited to any who will sue for the same. 12 Geo. II. c. 28. See Disney's Laws of Gaming, Wagers, &c.

GAMING, *laws of.* These are founded on the doctrine of chances. See CHANCE.

Mr. de Moivre, in a treatise De Mensura Sortis, has computed the variety of chances in several cases that occur in gaming, the laws of which may be understood by what follows.

Suppose p the number of cases in which an event may happen, and q the number of cases wherein it may not happen, both sides have the degree of probability, which are to each other as p to q.

If two gamesters, A and B, engage on this footing, that if the cases p happen, A shall win; but if q happen, B shall win, and the stake be a; the chance of A will be $\frac{pa}{p+q}$, and that of B $\frac{qa}{p+q}$; consequently, if they sell the expectancies, they should have that for them respectively.

If A and B play with a single die, on this condition, that if A throw two or more aces at eight throws, he shall win; otherwise B shall win; what is the ratio of their chances? Since there is but one case wherein an ace may turn up, and wherein it may not, let $a = 1$, and $b = 5$. And again, since there are eight throws of the die, let $n = 8$; and you will have $\overline{a+b}^{n} - b^{n} - nab^{n-1}$, to $b^{n} + nab^{n-1}$: that is, the chance of A will be to that of B, as 663991 to 10156525, or nearly as 2 to 3.

A and B are engaged at single quoits, and after playing some time, A wants 4 of being up, and B 6; but B is so much the better gamester, that his chance against A upon a single throw would be as 3 to 2; what is the ratio of their chances? Since A wants 4, and B 6, the game will be ended at nine throws; therefore, raise $a + b$ to the ninth power, and it will be $a^9 + 9a^8b + 36a^7bb + 84a^6b^3 + 126a^5b^4 + 126a^4b^5$, to $84a^3b^6 + 36aab^7 + 6ab^8 + b^9$; call a 3, and b 2, and you will have the ratio of chances in numbers, viz. 1759077 to 194048.

A and B play at single quoits, and A is the best gamester, so that he can give B 2 in 3, what is the ratio of their chances at a single throw? Suppose the chances as z to 1, and raise $z + 1$ to its cube, which will be $z^3 + 3z^2 + 3z + 1$. Now, since A could give B 2 out of 3, A might undertake to win three throws running, and, consequently, the chances in this case will be as z^3 to $3z^2 + 3z + 1$. Hence $z^3 = 3z^2 + 3z + 1$; or, $2z^3 = z^3 + 3z^2 + 3z + 1$. And therefore, $z\sqrt[3]{2} = z + 1$; and, consequently, $z = \frac{1}{\sqrt[3]{2} - 1}$. The chances, therefore, are $\frac{1}{\sqrt[3]{2} - 1}$, and 1, respectively.

Again, Suppose I have two wagers, depending, in the first of which I have 3 to 2 the best of the lay, and in the second 7 to 4, what is the probability I win both wagers?

1. The probability of winning the first is $\frac{3}{5}$, that is, the number of chances I have to win, divided by the number of all the chances: the probability of winning the se-

cond is $\frac{7}{11}$: therefore, multiplying these two fractions together, the product will be $\frac{21}{55}$, which is the probability of winning both wagers. Now, this fraction being subtracted from 1, the remainder is $\frac{34}{55}$, which is the probability I do not win both wagers; therefore the odds against me are 34 to 21.

2. If I would know what the probability is of winning the first, and losing the second, I argue thus: the probability of winning the first is $\frac{3}{5}$, the probability of losing the second is $\frac{4}{11}$; therefore multiplying $\frac{3}{5}$ by $\frac{4}{11}$, the product $\frac{12}{55}$ will be the probability of my winning the first, and losing the second; which being subtracted from 1, there will remain $\frac{43}{55}$, which is the probability I do not win the first, and at the same time lose the second.

3. If I would know what the probability is of winning the second, and at the same time losing the first, I say thus: the probability of winning the second is $\frac{7}{11}$; the probability of losing the first is $\frac{2}{5}$: therefore, multiplying these two fractions together, the product $\frac{14}{55}$ is the probability I win the second, and also lose the first.

4. If I would know what the probability is of losing both wagers, I say, the probability of losing the first is $\frac{2}{5}$, and the probability of losing the second $\frac{4}{11}$; therefore, the probability of losing them both is $\frac{8}{55}$; which being subtracted from 1, there remains $\frac{47}{55}$: therefore, the odds of losing both wagers is 47 to 8.

This way of reasoning is applicable to the happening or failing of any events that may fall under consideration. Thus, if I would know what the probability is of missing an ace four times together with a die, this I consider as the failing of four different events. Now the probability of missing the first is $\frac{5}{6}$, the second is also $\frac{5}{6}$, the third $\frac{5}{6}$, and the fourth $\frac{5}{6}$; therefore the probability of missing it four times together is $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{625}{1296}$; which being subtracted from 1, there will remain $\frac{671}{1296}$, for the probability of throwing it once or oftener in four times; therefore the odds of throwing an ace in four times, is 671 to 625.

But if the flinging of an ace was undertaken in three times, the probability of missing it three times would be $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{125}{216}$; which being subtracted from 1, there will remain $\frac{91}{216}$ for the probability of throwing it once or oftener in three times; therefore the odds against throwing it in three times are 125 to 91.

Again, suppose we would know the probability of throwing an ace once in four times, and no more: since the probability of throwing it the first time is $\frac{1}{6}$, and of missing it the other three times is $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6}$, it follows that the probability of throwing it the first time, and missing it the other three successive times, is $\frac{1}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{125}{1296}$; but because it is possible to hit it every throw as well as the first, it follows, that the probability of throwing it once in four throws, and missing the other three, is $\frac{4 \times 125}{1296} = \frac{500}{1296}$; which being subtracted from 1, there will remain $\frac{796}{1296}$ for the probability of throwing it once, and no more, in four times. Therefore, if one undertake to throw an ace once, and no more, in four times, he has 500 to 796 the worst of the lay, or 5 to 8 very near.

Suppose two events are such, that one of them has twice as many chances to come up as the other, what is the probability that the event which has the greater number of chances to come up, does not happen twice before the other happens once, which is the case of flinging 7 with two dice before 4 once? Since the number of chances are as 2 to 1, the probability of the first happening before the second is $\frac{2}{3}$, but the probability of its happening twice before it, is but $\frac{2}{3} \times \frac{2}{3}$, or $\frac{4}{9}$; therefore it is 5 to 4 seven does not come up twice before four once.

But if it were demanded, what must be the proportion of the facilities of the coming up of two events, to make that which has the most chances come up twice, before the other comes up once, the answer is 12 to 5 very nearly: whence it follows, that the probability of throwing the first before the second is $\frac{12}{17}$, and the probability of throwing it twice is $\frac{12}{17} \times \frac{12}{17}$, or $\frac{144}{289}$; therefore, the probability of not doing it is $\frac{145}{289}$: therefore the odds against it are as 145 to 144, which comes very near an equality.

Suppose there is a heap of thirteen cards of one colour, and another heap of thirteen cards of another colour, what is the probability that, taking one card at a venture out of each heap, I shall take out the two aces?

The probability of taking the ace out of the first heap is $\frac{1}{13}$, the probability of taking the ace out of the second heap is $\frac{1}{13}$; therefore the probability of taking out both aces is $\frac{1}{13} \times \frac{1}{13} = \frac{1}{169}$, which being subtracted from 1, there will remain $\frac{168}{169}$: therefore the odds against me are 168 to 1.

In cases where the events depend on one another, the manner of arguing is somewhat altered. Thus, suppose that out of one single heap of thirteen cards of one colour, I should undertake to take out first the ace; and, secondly, the two: though the probability of taking out the ace be $\frac{1}{13}$, and the probability of taking out the two be likewise $\frac{1}{13}$; yet, the ace being supposed as taken out already, there will remain only twelve cards in the heap, which will make the probability of taking out the two to be $\frac{1}{12}$; therefore the probability of taking out the ace, and then the two, will be $\frac{1}{13} \times \frac{1}{12}$.

In this last question the two events have a dependance on each other, which consists in this, that one of the events being supposed as having happened: the probability of the other's happening is thereby altered. But the case is not so in the two heaps of cards.

If the events in question be n in number, and be such as have the same number a of chances by which they may happen, and likewise the same number b of chances by which they may fail, raise $a+b$ to the power n. And if A and B play together, on condition that either one or more of the events in question happen, A shall win, and B lose, the probability of A's winning will be $\frac{\overline{a+b}|^{n} - b^{n}}{\overline{a+b}|^{n}}$; and that of B's winning will be $\frac{b^{n}}{\overline{a+b}|^{n}}$; for when $a+b$ is actually raised to the power n, the only term in which a does not occur is the last b^{n}: therefore, all the terms but the last are favourable to A.

Thus, if $n = 3$, raising $a+b$ to the cube $a^3 + 3a^2b + 3ab^2 + b^3$, all the terms but b^3 will be favourable to A; and therefore the probability of A's winning will be $\frac{a^3 + 3a^2b + 3ab^2}{\overline{a+b}|^{3}}$, or $\frac{\overline{a+b}|^{3} - b^3}{\overline{a+b}|^{3}}$; and the probability of

B's winning will be $\frac{b^3}{\overline{a+b}|^3}$. But if A and B play on condition, that if either two or more of the events in question happen, A shall win; but in case one only happen, or none, B shall win; the probability of A's winning will be $\frac{\overline{a+b}|^n - nab^{n-1} - b^n}{\overline{n+b}|^n}$; for the only two terms in which *aa* does not occur, are the two last, viz. nab^{n-1} and b^n. See CHANCE.

GAMMONING, among seamen, denotes several turns of rope taken round the bowsprit, and reeved through holes in knees of the head, for the greater security of the bowsprit.

GAMMUT, in music, the name given to the table or scale laid down by Guido, and to the notes of which he applied the monosyllables *ut, re, mi, fa, sol, la*. Having added a note below the proslambanomenos, or lowest tone of the ancients, he adopted for its sign the gamma, or third letter of the Greek alphabet; and hence his scale was afterwards called gammut. This gammut consisted of twenty notes, viz. two octaves and a major-sixth. The first octave was distinguished by capital letters, as G, A, B, &c. the second by small letters, *g, a, b*, &c. and the supernumerary sixth by double letters, as *gg, aa, bb*, &c. By the word gammut, we now generally understand the whole present existing scale; and to learn the names and situations of its different notes is to learn the gammut. It. however, sometimes simply signifies the lowest note of the Guidonian or common compass.

GANG, in the sea language, the same with crew. The company with which a ship's boat is manned is called the cockswain's crew or gang.

GANG, or GANGUE, in mineralogy. The word gang is used by German mineralogists to denote a metallic vein. Now, it is not often that these veins consist entirely of ore; in general they contain stony matter besides. For instance, in the copper-mine at Airthry, near Stirling, the copper ore is merely a narrow stripe in the middle of the vein, and the rest of it is filled up with sulphat of barytes. We use the word *gangue* as the French do, to denote not the metallic vein, but the stony matter which accompanies the ore in the vein. The gangue of the copper ore at Airthry is sulphat of barytes.

GANG-WAY, is the several passages or ways from one part of the ship to the other; and whatever is laid in any of those passages is said to lie in the gang-way.

GANGLIO, or GANGLION. See SURGERY.

GANGRENE. See SURGERY.

GANTLET, or GAUNTLET, a large kind of glove made of iron, and the fingers covered with small plates. It was formerly worn by cavaliers, when armed at all points.

GAOL. Gaols are of such universal concern to the public, that none can be erected by any less authority than an act of parliament. 2 Inst. 705.

All prisons and gaols belong to the king, although a subject may have the custody or keeping of them. 2 Inst. 100.

The justices of the peace at their general quarter-sessions, or the major part of them, provided that such major part shall not be less than seven, upon presentment made by the grand jury at the assizes of the insufficiency, inconvenience, or want of repair of the gaol, may contract for the building, repairing, or enlarging the same, together with the yards, courts, and outlets thereof, and adding such other building, and making such conveniences, as shall be thought requisite; or for erecting any new gaol within any distance not exceeding two miles from the site, and in that case for selling the old gaol and the site thereof, and also the materials of the old gaol; the contractors giving security to the clerk of the peace for the performance of the contract. 24 Geo. III. c. 54.

The expense of building, rebuilding, or enlarging such gaols, and such other necessary incidental expenses as aforesaid, shall be paid out of the county-rate; and when the account of such expense shall exceed half the amount of the ordinary annual assessment for the county rate (to be computed at a medium for the last proceeding five years), the justices in session may borrow in mortgage of the said rates any sum not less than 50*l*. nor exceeding 100*l*. and may order the growing interest and so much of the principal sum as shall be equal at least to such interest, to be paid off yearly, till the whole thereof shall be discharged, and an account thereof shall be kept in a book provided for that purpose; and such book shall be delivered into court at every quarter-session to be inspected by the justices, who shall make such orders relating thereto as to them shall seem meet: provided that the whole sum of money borrowed be fully paid within fourteen years from the time of borrowing it. *Id.*

As there are several persons confined in the county and city gaols under sentence and order made by one or more justices at their sessions, or otherwise, upon conviction in a summary way without the intervention of a jury; it is therefore, by 24 Geo. III. *c.* 56., enacted, that any judge of assize, or two justices, within whose jurisdiction such gaol is situated, may remove such persons to any house of correction within the same jurisdiction, there to be confined, and to remain in execution of such sentence or order.

For the relief of prisoners in gaols, justices of the peace in sessions have power to tax every parish in the county, not exceeding 6*s*. 8*d*. per week, leviable by constables, and distributed by collectors, &c. 12 Car. II. c. 29.

But it is observed by lord Coke, that the gaoler cannot refuse the prisoner victuals, for he ought not to suffer him to die for want of sustenance. 1 Inst. 295.

If any subject of this realm shall be committed to prison for any criminal or supposed criminal matter, he shall not be removed thence, unless by habeas corpus, or some other legal writ; or where he is removed from one prison or place to another within the same county, in order to his trial or discharge; or in case of sudden fire or infection, or other necessity; on pain that the person signing any warrant for such removal, and he who executes the same, shall forfeit to the party grieved 100*l*. for the first offence, and 200*l*. for the second, &c.

GAOL OF PRISON BREAKING, at the common law, was

felony, for whatever cause the party was imprisoned; but by 1 Ed. II. st. 2. the severity of the common law is mitigated, which enacts, that no person shall have judgment of life or member, for breaking prison, unless committed for some capital offence; so that, unless the commitment is for treason or felony, the breaking of prison is not felony, but is otherwise punishable as a misdemeanor only, by fine and imprisonment. 4 Black. 130.

Any place whatever, wherein a person under a lawful arrest for a supposed crime is restrained of his liberty, whether in the stocks or street, or in the common gaol, or the house of a constable, or a private person, is a prison in this respect, for a prison is nothing else but a restraint of liberty; and therefore this extends as well to a prison in law, as to a prison in deed. 2 Inst. 589.

He that breaks prison may be proceeded against for such a crime, before he is convicted of the crime for which he is committed, because the breach of prison is a distinct independant offence; but the sheriff's return of a breach of prison is not a sufficient ground to arraign a man without an indictment. 2 Haw. 197.

It is not sufficient to indict a man generally for having feloniously broken prison; but the case must be set forth specially, that it may appear that he was lawfully in prison, and for a capital offence. 2 Inst. 591. Hale's P. C. 109.

GAOLER. Besides the duties enjoined on gaolers by act of parliament, and the abuses for which by statute they are punishable, the common law subjects them to fine and imprisonment, as also to the forfeiture of their offices, for gross and palpable abuses in the execution of their offices. 2 Inst. 381.

Also gaolers are punishable by attachment, as all other officers are, by the courts to which they more immediately belong, for any gross misbehaviour in their offices, or contempt of the rules of such courts, and punishable by any other courts for disobeying writs of habeas corpus awarded by such courts, and not bringing up the prisoner at the day perfixed by such writs. 2 Haw. 151.

If the gaoler, by keeping the prisoner more strictly than he ought, occasions the prisoner's death, this is felony in the gaoler by the common law. Therefore, if a prisoner dies in gaol, the coroner ought to sit upon him; and if the death was occasioned by cruel and oppressive usage on the part of the gaoler, or any officer of his, it will be deemed wilful murder in the person guilty of such duress. 3 Inst. 91.

But if a criminal endeavouring to break gaol, assaults the gaoler, he may be lawfully killed by him in the affray. Jenk. 23. 1 Haw. 71.

A gaoler is considered as an officer relating to the administration of justice, and is under the same special protection of the law that other ministers of justice are. If a person threatens him for keeping a prisoner in safe custody, he may be indicted, and fined and imprisoned for it. 2 Rol. Abr. 71.

If in the necessary discharge of his duty he should meet with resistance, whether from prisoners in civil or criminal suits, or from others in behalf of such prisoners, he is not obliged to retreat as far as he can with safety, but may freely and without retreating repel force with force; and if the party so resisting happens to be killed, this will be justifiable homicide in the gaoler or his officer, or any person coming in aid of him. On the other hand, if the gaoler or his officer, or any person in aid of him, should fall in the conflict, this will amount to wilful murder in all persons joining in such resistance; for it is homicide in defiance of the justice of the kingdom. Fost. 321.

The justices in their sessions, or in any special adjournment held for such express purpose, may, if they shall think it necessary or proper, appoint salaries or allowances to gaolers, in lieu of the profits derived from the sale of liquors, as to them shall seem meet, and order the same to be paid out of the county-rate, by a certificate of such allowance being signed by the chairman of the sessions: but no chairman shall sign such certificate, unless notice of such intended application, signed by the clerk of the peace, has been given 14 days at least before the holding of such session or adjournment thereof, by two several advertisements in some newspaper which shall be printed and circulated in such county. 24 Geo. III. c. 54.

It seems clearly agreed, that a gaoler, by suffering voluntary escapes, by abusing his prisoners, by extorting unreasonable fees from them, or by detaining them in gaol after they have been legally discharged, and paid their just fees, forfeits his office; for that in the grant of every office it is implied, that the grantee executes it faithfully and diligently. Co. Lit. 233.

GAOL-DELIVERY. By the law of the land, that men might not be long detained in prison, but might receive full and speedy justice, commissions of gaol-delivery are issued out, directed to two of the judges, and the clerk of assize associate; by virtue of which commission, they have power to try every prisoner in the gaol, committed for any offence whatsoever.

GARBE, in heraldry, a sheaf of any kind of grain, said to represent summer, as a bunch of grapes does autumn.

GARBOARD-STRAKE, the plank next the keel of a ship, one edge of which is run into the rabbit made in the upper edge of the keel on each side.

GARCINIA, a genus of the monogynia order, in the dodecandria class of plants, and in the natural method ranking under the 18th order, bicornes. The calyx is tetraphyllous inferior: there are four petals: the berry is octospermous, and crowned with a shield-like stigma. There are three species. The mangostana is a tree of great elegance, and producing the most pleasant fruit of any yet known.

This tree has been very accurately described by Dr. Garcin, in honour of whom, as its most accurate describer, Linnæus gave it the name of Garcinia, in the 35th volume of the Philosophical Transactions. It grows, he informs us, to about 17 or 18 feet high, "with a straight taper stem like a fir," having a regular tuft in form of an oblong cone, composed of many branches and twigs, spreading out equally on all sides without leaving any hollow. Its leaves, he observes, are oblong, pointed at both ends, entire, smooth, of a shining green on the upper side, and of an olive on the back. Its flower is composed of four petals almost round or a little pointed: its colour resembles that of a rose, only deeper and less lively. The calyx of the flower is of one piece, expanded, and cut into four lobes. The two upper lobes are

something larger than the lower ones: they are greenish on the outside, and of a fine deep red within: the red of the upper ones is more lively than that of the lower ones. This calyx incloses all the parts of the flower; it is supported by a pedicle, which is green, and constantly comes out at the end of a twig above the last pair of leaves. The fruit is round, of the size of a small orange, from an inch and a half to two inches diameter. The body of this fruit is a capsule of one cavity, composed of a thick rind a little like that of a pomegranate, but softer, thicker, and fuller of juice. Its thickness is commonly a quarter of an inch. Its outer colour is of a dark-brown purple, mixed with a little grey and dark-green. The inside of the peel is of a rose-colour, and its juice is purple. Last of all, this skin is of a styptic or astringent taste, like that of a pomegranate; nor does it stick to the fruit it contains. The inside of this fruit is a furrowed globe, divided into segments much like those of an orange, but unequal in size, which do not adhere to each other. The number of these segments is always equal to that of the rays of the top which covers the fruit. The fewer there are of these segments the larger they are. There are often in the same fruit segments as large again as any of those that are on the side of them. These segments are white, a little transparent, fleshy, membranous, full of juice like cherries or raspberries, of a taste of strawberries and grapes together. Each of the segments incloses a seed of the figure and size of an almond stripped of its shell, having a protuberance on one of its sides. These seeds are covered with two small skins, the outermost of which serves for a basis to the filaments and membranes of which the pulp is composed. The substance of these seeds comes very near to that of chesnuts, as to their consistency, colour, and astringent quality.

"This tree (according to our author) originally grows in the Molucca islands, where it is called mangostan, but has been transplanted to the islands of Java and Malacca, at which last place it thrives very well. Its tuft is so fine, so regular, so equal, and the appearance of its leaves so beautiful, that it is at present looked upon at Batavia as the most proper for adorning a garden, and affording an agreeable shade. There are few seeds, however, (he observes) to be met with in this fruit that are good for planting, most part of them being abortive." He concludes his description by mentioning that one may eat a great deal of this fruit without any inconvenience; and that it is the only one which sick people may be allowed without any scruple.

Other writers concur in their praise of this fruit. Rumphius observes, that the mangostan is universally acknowledged to be the best and wholesomest fruit that grows in India; that its flesh is juicy, white, almost transparent, and of as delicate and agreeable a flavour as the richest grapes; the taste and smell being so grateful that it is scarcely possible to be cloyed with eating it. He adds, that when sick people have no relish for any other food, they generally eat this with great delight; but should they refuse it, their recovery is no longer expected. "It is remarkable (says he) that the mangostan is given with safety in almost every disorder. The dried bark is used with success in the dysentery and tenesmus, and an infusion of it is esteemed a good gargle for a sore mouth or ulcers in the throat. The Chinese dyers use this bark for the ground or basis of a black colour, in order to fix it the firmer."

According to captain Cook, in his Voyage round the World, vol. iii. p. 737, the garcinia mangostana of Linnæus is peculiar to the East Indies. It is about the size of the crab-apple, and of a deep red-wine colour. On the top of it is the figure of five or six small triangles joined in a circle, and at the bottom are several hollow green leaves, which are remains of the blossom. When they are to be eaten, the skin or rather flesh must be taken off, under which are found six or seven white kernels, placed in a circular order; and the pulp with which these are enveloped is the fruit, than which nothing can be more delicious. It is a happy mixture of the tart and the sweet, which is no less wholesome than pleasant, and, as well as the sweet orange, is allowed in any quantity to those who are afflicted with fevers either of the putrid or inflammatory kind.

GARDENIA, a genus of the pentandria monogynia class and order. The corolla is one-petalled, contorted or twisted; stigma lobed; berry inferior, two or four celled, many-seeded. There are 15 species, chiefly shrubs of the Cape and Japan. They are known in our stoves by the name of Cape jasmin, and some of them are highly ornamental. They are propagated by cuttings, plunged in a hotbed, &c.

GARDENING. This art, so natural to man, so improving to health, so conducive to the comforts and the best luxuries of life, may properly be divided into two branches; practical, and picturesque or landscape gardening.

The former is what every person, except the inhabitants of populous cities, has more or less occasion to practise; the latter is a privilege which only the very opulent can enjoy, and which must consequently be the elegant amusement of a chosen few.

Picturesque or landscape gardening should certainly never be attempted on a small scale. Indeed we are not certain that we may not be incurring a solecism in applying the term gardening to this department of agriculture. It is properly the art of laying out grounds; and the park or the farm, not the garden, is its object. It never can be attempted with success on a smaller scale than 20 acres; but 50 or 100, or even more, are better adapted to the design.

That style of gardening which would unite both objects, and which would give a picturesque effect to an acre or two of ground, is truly absurd. Many an improvident citizen wastes unprofitably the morsel of earth which should grow cabbages for his family, on an unprofitable grass-plat or shrubbery, on serpentines and mazes, and fish-ponds; or even on cascades, to the infinite annoyance of his visitors, the prejudice of his own health, and the merriment of all persons of true taste. This mania for the picturesque would have been not less deserving the ridicule of an Addison, than the perverse taste which displayed our first parents in yew, and the Graces and Muses in Portugal laurel.

A garden, properly speaking, is a small spot of ground attached to the house. As the house is itself a regular and formal object, so we naturally expect something of the same regularity in this appendage. Neatness too is

one of the chief excellencies of a garden, and this is found to be wholly inconsistent with this rage for the picturesque. Littered walks, and parched and cankered vegetables, with a wretched patch of green in the middle where a weekly exhibition is made from the buck-basket, are the usual effects of this rus-in-urbe taste; while all the real beauty, neatness, and utility, which a small spot of ground is really capable of affording, are preposterously neglected.

It is also fashionable to make a separation between the pleasure and the kitchen garden. This may indeed preserve the few shrivelled fruit which the latter, on a diminutive scale, is capable of affording, from the hands of rapacious visitors; but the range of the proprietor becomes by this appointment most deplorably limited and diminished; and the vegetables will want what alone can render them fine and flourishing, the free circulation of air.

For our own parts we cannot enter into that fastidiousness of taste, which can see no beauty in the esculent vegetables. There is a variety, and often a beauty, in their foliage, not inferior to the furniture of a shrubbery. The common pea, was it an exotic, would be admired for its milk-white blossom; and the bean for its agreeable fragrance. Few hot-house plants can vie in colour, or even in habit and growth, with the scarlet runner; and even the plants of more humble growth are not wholly destitute of beauty.

The garden of which we shall in the first place treat, as taking that practical view of the subject which is consistent with our design, is one in which vegetables, fruits, and flowers, are cultivated under the same inclosure. The work of making a new garden can happen to few; and when it does, soil, situation, and space, all favourable, are happy circumstances not always at command. It often happens, however, that pieces of ground are taken into use as additions; and some judgment should be exercised in the choice, that the business may be well effected.

With respect to the extent, a general idea may be given in observing, that an acre with wall-trees, hot-beds, pots, &c. will furnish employment for a man, who at some busy times will even need assistance. The size of the garden should, however, be proportioned to the house, as to the number of inhabitants it does or may contain. This is naturally dictated; but yet it is better to have too much ground allotted than too little, and there is nothing monstrous in a large garden annexed to a small house.

Some families use few, others many vegetables, and it makes a great difference whether the owner is curious to have a long season of the same production, or is content to have a supply only at the more common times. But to give some rule for the quantity of ground to be laid out, a family of four persons (exclusive of servants) may have a rood of good working open ground, and so in proportion.

But if possible let the garden be rather extensive according to the family; for then a useful sprinkling of fruit-trees can be planted in it, which may be expected to do well, under the common culture of the ground about them; a good portion of it also may be allotted for that agreeable fruit the strawberry in all its varieties; and the very disagreeable circumstance of being at any time short of vegetables will be avoided. It should be considered also, that artichokes, asparagus, and a long succession of peas and beans, require a good deal of ground. Hotbeds will also take up some room, if any thing considerable is done in the way of raising cucumbers, melons, flowers, &c.

The situation of a garden should be dry, but rather low than high, and as sheltered as can be from the north and east winds. These points of the compass should be guarded against by high and good fences; by a wall of at least ten feet high; lower walls do not answer so well for fruit-trees, though one of eight may do. A garden should be so situated, to be as much warmer as possible than the general temper of the air is without, or ought to be made warmer by the ring and subdivision fences. This advantage is essential to the expectation we have from a garden locally considered.

As to trees planted without the wall, to break the wind, we cannot expect to reap much good this way, except from something more than a single row, *i. e.* a plantation. Yet the fall of the leaves by the autumnal winds is troublesome, and a high wall is therefore advisable. Spruce firs have been used in close-shorn hedges; which, as evergreens, are proper enough to plant for a screen in a single row, though not very near to the wall; but the best evergreens for this purpose are the evergreen oak and the cork-tree. The witch elm, planted close, grows quick, and has a pretty summer appearance behind a wall; but is of little use then as a screen, except to the west; where still it may shade too much (if planted near), as it mounts high. In a dry hungry soil the beech also is very proper; and both bear cutting. The great maple, commonly called the sycamore, is handsome, of quick growth, and being fit to stand the rudest blasts, will protect a garden well in every exposed situation: the wind to be chiefly guarded against as to strength, in most places, being westerly.

The form of a garden may be a square, but an oblong is preferred, and the area rather a level; or if there is any slope it should be southward, a point either to the east or west not much signifying; but not to the north, if it can be avoided, because crops come in late, and plants do not stand the winter so well, in such a situation. A garden with a northern aspect has, however, its advantages, being cooler for some summer productions, as strawberries, spring-sown cauliflowers, &c. and therefore to have a little ground under cultivation so situated is desirable, especially for late succession crops.

The soil that suits general cultivation best is a loam, rather the red than the black; but there are good soils of various colours, and this must be as it happens. The worst soil is a cold heavy clay, and the next a light sand; a moderate clay, however, is better than a light soil, though not so pleasant to work. If the soil is not good, *i. e.* too poor, too strong, or too light, it is to be carefully improved without delay. Let it first, at least, be thoroughly broken and cleaned of all rubbish, to a regular level depth at bottom as well as at top, so as to give full eighteen inches of working mould, if the good soil will admit of it; none that is bad should be thrown up for use, but rather moved away. This rule of bottom levelling is particularly necessary when there is clay be-

low, as it will secretly hold up wet, which should not stand in any part of the garden. (See DRAINING.) When a piece of ground is cleared of roots, weeds, stones, &c. it would be of advantage to have the whole thrown into two-feet-wide trenches, and lie thus as long as conveniently may be. The ground cannot be too well prepared; for when this business is not performed to the bottom at first, it is often neglected, and is not conveniently done afterwards; and so it happens, that barely a spade's depth (or less) is too often thought sufficient to go on with. There is this great advantage of a deep staple, that in the cultivation of it the bottom may be brought to the top every other year, by double trenching; and being thus renewed, less dung will do, and sweeter vegetables be grown. Tap-rooted things, as carrots and parsnips, require a good depth of soil.

The aspect of the wall designed for the best fruits may be full south; or rather inclining to the east, by which it will catch the sun's rays at its rise, the cold-night dews be earlier and more gently dissipated, and the scorching rays of the afternoon summer's sun are sooner off. By thus having the walls of a garden not directly to the four points, the north wall is greatly advantaged by having more sun.

The border next this wall should be of very good earth, about two feet deep, rising a little towards the wall. A free moderate loam, or some fresh maiden soil, not too light, is necessary: and if it is not naturally there, let no trouble be spared to procure it, if it can be had, so as to make all the borders promising good; and in order to this, if manure is necessary, let it rather be that of rotted vegetables, or turf, with a small quantity of wood-ashes; for the roots of fruit-trees should not meet with much dung, at least of horses: that of cows is the best, or that of sheep and hogs will do well rotted, well mixed, &c. being worked in the borders as long as possible before the trees are so planted. Let the holes be some time opened beforehand, that they may be improved by exposure to the atmosphere. Thus due care will be taken, and all things be ready to go about the work of planting properly.

The borders for peaches, &c. cannot be too wide, for in a few years the roots will spread a considerable way: and that they may do it without impediment of rubbish in the walks, and without meeting with a bad soil, is of the greatest consequence to the future health and fruitfulness of the trees.

If a garden is large and square, a second south wall, running down the middle of it, would be very useful; and so, if large and long, a cross wall or two might be adopted, as giving opportunity for the cultivation of more trained fruit-trees, these intersecting walls, ranging east and west, are proper for it (as situated within the ring-fence), furnished with flues, &c.

The best fruit-border being prepared for peaches, nectarines, and apricots, or vines and figs, the trees should take their residence there (if the leaf is falling) about the latter part of October, or as soon after as can be. If the middle of December is past, February is then the time; though gardeners plant all winter, if the weather is open enough at the time to work the ground. March, however, may do, or even the beginning of April.

Wall-trees should not be older than two years from grafting or budding. Much disappointment has been the consequence of planting old trained trees, through their being accustomed (perhaps) to a contrary soil, or by damage done to the roots in taking the trees up; and thus, instead of saving time, it has frequently been lost, being obliged (after years) to be replaced with young ones. But if trained trees are to be made use of, let them be planted as early, and with as full roots as possible, and in a good soil. Except in fine situations as to sun, shelter, and climate, never plant early and late peaches; as the first may be cut off, and the latter not ripen.

The distance to plant should be about 12 inches from the wall: and let apricots, peaches, and nectarines, be twenty feet asunder, more or less, according to the height of the wall; though for the small early sorts fifteen or sixteen feet will do. As the larger apricots, however, grow freely, and do not well endure the knife, they ought to have twenty-five feet allowed them. This is for a wall of nine or ten feet high; if higher, the distance may be less, and if lower, the contrary. This room may seem to some too great; but when trees are planted in too confined a space, after a few years it is troublesome to keep them pruned within bounds: and the cutting they must have makes them run to wood, and thus to become less fruitful. Fig-trees require as much room as the apricot, or rather more; as they grow freely, and are to extend without shortening. Though other trees are best planted in October, the fig should not be till March.

The intermediate spaces between peaches, nectarines, and apricots, may have a vine, a dwarf cherry, or currant or gooseberry tree of the early sorts, as the smooth green and small red, to come in early; and will be improved in the beauty, size, and flavour, of their fruit, by the advantage of situation. But wherever grapes can be expected to ripen, there let a young plant, or cutting, be set, though the space should be confined; for the vine, freely as it shoots, bears the knife well to keep it within bounds. If the wall is high, the cherry or plum may be half-standards; which being after a while kept above, will be more out of the way of the principal trees; though dwarfs may be trained so as not to interfere. Some have planted half-standards of the same kind of fruit as the dwarfs: but whichever mode is adopted, let the intermediate trees be pruned away below in good time, in order to accommodate the principals freely as they mount and extend. The better way however is, when the wall is tolerably covered to extirpate the intermediate trees; as, when large, they impoverish the border, and rob the principals of nutriment. If taken up well in season, and pruned properly, they may be planted elsewhere. Something merely ornamental may occupy the vacancies also, as some double-blossomed fruit-tree, passion-tree, roses, &c. or in a fine situation a pomegranate; any of which may be removed when their room is wanted.

Plums, cherries, and pears, may occupy the other walls; the two former at about fifteen feet, or it may be twenty feet asunder. Cherries, except the morella, will not do well in a full north aspect; but any sort of plum (rather a late one) and summer pears, and also nut-trees, will, if you chuse to train them. There should always be some currants and gooseberries in an east and north

situation, at the distance of eight feet. where they will be easily matted, when ripe, to come in late, as October, November, or perhaps December. Pear trees of free growth are hardly to be kept within tolerable compass on low walls; but if attempted, should have at least thirty feet allowed them. The best sorts of winter pears deserve a southerly wall to ripen them well, and improve them in size and flavour. The gable end of a house is well adapted for a pear-tree, as it affords room, which they require. Apples may do on a wall (and if any on a good wall, let it be the golden-pippin), yet the practice is seldom adopted. The same may be said of mulberries, though they come to bearing much sooner against a wall; but they need not have a south aspect, indeed it has been asserted that they succeed the best in a north one. For furnishing walls chuse trees of moderate wood, young, well rooted, clean, and healthy.

When the planting of a garden is finished, it will be a good way to have a plan of it taken, with the name of every peculiar tree marked on it in their place, to be assured of the sorts when they come to bear. Some have the names of the trees painted on boards, and placed behind them; to which if added the time of ripening, (fixed late enough) it would tend to prevent a premature plucking by visitors, &c.

Here it may be observed, that if any ever-green hedges are desired in or about the garden, yew, box, alaternus, celastrus, phillyrea, and pyracantha, may be kept low, and clipped in form, if so desired; in addition to which, if a few roses were intermixed, it would have a very pretty effect. A deciduous hedge for subdivision, or screen, &c. may be made of elms or limes, setting the larger plants at five feet asunder, and a smaller one between. Or an ordinary fence, or subdivision, may be quickly formed of elder cuttings, stuck in at two feet asunder, which may be kept cut within bounds.

A wide border next the south wall, as was said, is best for the trees; and moreover for the many uses that may be made of it for the smaller early, or late tender esculents, and a few early cauliflowers. For the sake of a pleasant warm walk in spring, to have the south border narrow may be desirable; but on no account let it be less than six feet. Take care that this walk is not sunk too much; and that it have a bottom of good earth, as deep as where the trees are planted. Let the body of gravel be thin, and then the roots of the trees will be admitted to run properly under the walk, and find wholesome nourishment; where, if they were stopped by rubbish, they would be apt to canker, and irrevocably disease the trees.

The number and breadth of the walks must in a measure be determined by the quantity of allotted ground; exceeding in these particulars where there is room. But few and wide walks are better than many and contracted. If the garden is small, one good walk all round is sufficient: and if long and narrow, the cross walks should not be many; six or eight feet walks are not too wide for a moderate-sized garden.

If the ground is laid out in autumn, defer the making of the walks till spring, when the earth will be settled. Gravel laid towards winter would be disturbed by the frost, and the necessary work about the quarters and borders. But whenever made, the garden ought to be brought to an exact level, or slope; then the walks should be stumpt, keeping the tops of the stumps very level (as guides) to the true pitch of the quarters by a light line, made of good hemp, that will bear pulling tight. Proceed to take the earth out of the alleys about eight inches deep, which may be thrown towards the middle of the quarters, to give them a small convexity, which makes them look well.

Rake the bottom of the walk level, and lay the gravel to within two inches of the top of the stumps. The gravel will settle a little, but the walks should always be about three or four inches at their edge, below the quarters, or these will have a flat, and so a mean appearance.

If edgings are to be made, in order to separate between the earth and gravel, especially if of stone, or wood, or box, they should be done first, and they will be a good rule to lay the box by.

If you have plenty of gravel, lay it moderately fine; if little, some small stones, or rubbish of any kind, may be laid in first, and rammed down level with a broad rammer; but do not spare for a little expense, if gravel can be had, as a thick coat of fine gravel will bear relaying, or turning over, to refresh it occasionally in the spring. As the gravel is laid, let the operator neatly rake the larger parts down to the bottom, leaving a fine surface, in a small degree convex, *i. e.* just barely sufficient to throw off wet; walks that lie very high in the middle are unpleasant to both eye and feet, and cannot be so well rolled and kept in order.

When deep walks of gravel are designed, for the sake of the mould dug out of the alleys, it should be forborne, and laid thin, if any trees are intended to be planted near the edge: for if the roots of trees have not a good soil to strike into, when they reach the walks, they will not prosper. In laying gravel very thick it is a good way to do it at two courses; the first of which may be rough, as it comes from the pit, yet still raking the larger parts down, and then ramming or treading it; and the last course should be all of screened materials.

It is best to lay a few yards of gravel only at a time, before ramming or treading: after which it may be necessary to go over it with a fine iron rake, tooth and back; and then a whole walk being finished, it should be repeatedly pressed with a moderately heavy roller; and again soon after the next rain that falls. So will the walks become nicely level and firm, in which their excellence consists.

Grass walks may answer where gravel is scarce; but the latter is so clearly preferable, that except for a little variety in large gardens where there are many walks, they will hardly be made choice of. They are troublesome to keep in order, and if much used are apt to get bare, and out of level, especially when narrow; they are also frequently damp to the feet.

Camomile has been used also to form green or carpet walks, planting it in sets about nine or ten inches asunder; which naturally spreading, the runners are fixed by walking on them, or rolling.

Sand may be adopted for walks, and there is a binding sort of it that does very well; but lay not any of it too thick, as it is the less firm for it. Drift sand is a good substitute for gravel.

Coal-ashes strewed thinly in the alleys are better than nothing, as they at least serve to keep the feet dry and clean. If the garden is of a strong soil, these ashes, when worn down, may be thrown out of the walks, with a little of the earth, and will prove a good manure for the quarters.

Sea-shells make very good walks.

All trees designed to be planted are to be thought of before winter. Those of the wall have been spoken of; and as to standards, they must have a fair depth of good soil to grow in, for it should be remembered, that tree roots in a garden are prevented from running over the surface, as they do in an undisturbed orchard. It is necessary that some caution should be used not to dig the ground too near and too deep about garden trees, lest loosening the roots they should not be able to stand the wind; and because the nearer the surface any root grows, the more and choicer fruit the tree bears.

But the fewer standard trees in a garden the better, as they take up much room, and by their shade prevent the proper growth of vegetables that are near them; so that if a garden is small, there should be no trees except those of the wall. The case is different where there is ample room; and the blossoms of fruit-trees (apples particularly) are so delightful, that if they produced nothing for the palate, there would be a sufficient inducement to plant them for ornament; but let them be dwarf standards in preference to espaliers.

Dwarf-standards occasion less trouble to keep them in order than espaliers, and are generally more productive; for espalier trees are seldom managed well, and thus appear unsightly: at best they are stiff and formal, and obstruct the sight in viewing the quarters of a garden, which, if in order, are worthy of coming under the eye; the violence done to nature, to keep espaliers in form, is commonly paid by disappointment. A writer of repute observes, apples on French paradise stocks, planted at eight or nine feet distance, pruned and kept in an easy manner, make a fine appearance, and produce better fruit, and in greater quantities, than when they are in espaliers. Dutch paradise stocks however last longer, and are altogether superior.

If espaliers are planted, let them be only fruit of the best sorts, and in spacious gardens, where they may have a good length and height allowed them to grow freely; and let it be resolved to do the business neatly. If they may have nothing better than poles or stakes to be trained to, let them at least be straight, and of some equality in size as to height and thickness, smooth, and not too clumsy for the purpose; fix them well in the ground, upright, and about nine inches asunder; at first only four feet from the ground, and raised as the trees advance in height. Apples on paradise stocks best suit for espaliers in small gardens, and pears on quince stocks, as they maintain a small size; but they are apt to decay by the cutting they must have, and so do not prove enduring trees.

Espalier trees should rather be trained to sawed materials properly framed together, smoothed, and painted. But for a year or two they may be fastened to light stakes, when they will have formed a head, to begin to train them for bearing in the neat manner proposed, that is, to slips of deal joined to light oak posts, as trellises. Whether the slips are placed perpendicularly, or longitudinally, seems indifferent. If the longitudinal mode of training is the best approved, strong iron wire may be recommended to run through the posts instead of slips of wood, as it shades less, and is stronger and neater. If upright slips are used, they should be slender, and from six to eight inches distance, according to the greater or less freedom of the natural growth of the tree. The height may be also according to the nature of the tree, from five to six feet, and it will not answer to have them lower. Only a moderate length of trellis (on each hand) need be fixed at first, and so additions made as the tree extends. The posts may be about four feet asunder; the first on each hand being two feet, or a yard, from the stem of the tree.

Apples should be allowed 24 feet, and pears 30; except those grafted on paradise or quince stocks, for which little more than half this distance may answer. Cherries and plums should have about 18 or 20 feet allowed them. Quinces, medlars, mulberries, and filberds, may also be espaliered. The trees should be planted about a yard from the edge, but farther off is better, if the walks lie deep of gravel or poor materials.

The Breda and Brussels apricots have succeeded in espaliers, as also in dwarf and full standards; but the general climate of the place must be mild, and the situation they are planted in must be very sunny and well sheltered. The fruit from standard apricots is very fine, and abundant; but they come not to bearing under several (sometimes 10 or 12) years.

Currants, gooseberries, and raspberries, do well espaliered, as to a production of early and fine fruit.

Trees of a more humble nature, and shrubs, next occupy attention in furnishing a garden. Currants and gooseberries (as bushes) should be planted three feet from the edge, and full six feet asunder. Some of these very useful shrubs should grow in every aspect of the garden, in order to have a succession of their fruits, as long as may be. Those who choose to plant whole quarters of currants and gooseberries ought to do it at six feet asunder in the rows, and the rows eight feet from one another.

Raspberries may be set in plantations, in rows five feet asunder, allowing three feet between the plants. These shrubs are always best by themselves, as otherwise their suckers over-run the quarters. Between rows of raspberries planted at the above distance, coleworts, early cabbages, cauliflowers, and lettuces, may be set, or spinach sowed in drills; the raspberries having had their pruning and dressing early in autumn, for the purpose. Every year a little short manure, dug in close about the roots, (and deeper as the plantation gets older) will insure fine fruit. Raspberries are not very nice as to soil and situation; but the twice-bearing sort should have a dry soil and warm birth to forward the crops, that the last may be in time. See that the plants to be set have good brushy roots, and two or three eyes to each root near the stems, for the next year's bearing. The smooth-wooded, or cane rasp, is to be preferred for a principal crop. The large, white, or Antwerp, is also good.

Strawberries may be planted at the edges of borders and quarters, either in single or double rows (rather the latter) for the convenience of gathering, and for orna-

ment; but the common and best way is, in four-feet beds, with eighteen-inch and two-feet alleys, on which beds may be five rows of the wood and alpine, four of the scarlet and pine-apple, three of the Carolina, and two of the Chili; setting the plants at the same distance in the rows, as the rows are from one another in what is called the quincunx order, that is, like the five of cards. In a good, cool, loamy soil, which suits them best, a little more distance may be allowed the first four sorts; and in a quite dry light soil, somewhat less, that they may shade one another the better from drought.

The best situation for strawberries is an open and sunny one, as thus they bear more, and finer-flavoured fruit. Some of the scarlets should be planted under warm walls to come early. The woods bear shade as natural to them, and the alpines do tolerably well in it. As lengthening the season of fruit is a desirable circumstance, for these three sorts (at least) the situation should be various.

The most proper time for planting the strawberry is the first moist weather in September, (or even earlier) that they may be established in the ground before winter, and they will bear the better the first year. Frost is apt to throw up late-planted ones, and injures, if not destroys them. Those planted in spring often suffer from drought, and bear very little thr first year, except the alpines. Choose forward runners for planting, and let them be from beds in full bearing, that is, of two or three years old; for plants from old beds are not so fruitful. Take care also they come from beds producing fruit good in its kind, and true as to sort: much depends on this. Press the mould to the roots, give them a watering, and again once or twice, if the weather proves dry. Some gardeners let them run over the beds, which in a dry light soil may be proper; but in this case, a greater distance should be allowed them at planting.

If the alpine sort is planted on a warm border, eighteen inches asunder, and suffered to spread, the first runners will fruit the same year, and sometimes this prolific strawberry bears till November.

Fresh plantations of strawberries should be made every fourth year, though in a good soil and with good management they will continue longer: so that where they are suffered to run, the plants being frequently renewed, and old ones removed, beds have borne tolerably for ten years. Some gardeners insist that this spreading mode is the best way of cultivating the strawberry. In a dry season, such full-covered beds have the advantage, but in a wet one the fruit is apt to rot, though still in such a season it is cleaner than from plants growing in an open way; but this carries the appearance of neglected culture. The method of keeping them in detached plants produces the largest and best-ripened fruit, and on the whole is preferable; for which practice there cannot be a stronger argument, than that those follow it who cultivate the strawberry for sale.

The watering of strawberries should not be neglected, doing it almost daily when in flower, and setting their fruit, if the weather proves dry, particularly to those under a warm wall; but this is not to be continued when the fruit is nearly ripe, which would spoil the flavour, and dispose them to decay.

Flowering shrubs may be dispersed about, and herbaceous perennial flowers; but plant them not too near the edge, lest they hang over the walks. The bulbous sorts may however, be within six inches, especially crocuses and snowdrops

Asparagus and artichokes should be thought of, but they take up much room, and in small gardens may therefore be left out. It will be of little use to have less than 50 or 60 feet of asparagus beds, as there would be so few heads to cut at a time; and artichokes must be planted wide, or they will not grow large and fleshy, in which their merit consists.

Let not pot-herbs be forgotten, but provide a general herbary in that part of the garden which is warmest, and best-shaded, for these are tender plants.

Having spoken of stationary things, the routine of the seasons must dictate the rest; and the inclinations of the palate will refresh the memory to take care of providing the most necessary and agreeable esculents for dressing, and raw salads.

Perennial flowers have been mentioned; but let fancy direct as many annuals and biennials to be cultivated, as room can conveniently be found for, that the garden may be, as much as possible. ornamented.

In furnishing a garden with shrubs and flowers, respect should be had to their usual height, their bulk, colour, and season, that the mixture may be properly varied, harmonious to the eye, and come in regular succession. The latter part of the year is seldom provided for so well as it might be; late flowers should be set in warm situations, as their proper place. In the most dreary months, by judicious planting, evergreens in their neat and cheerful " winter liveries," may be viewed from our windows, and serve instead of flowers.

Those who garden upon a large scale, should take care to have every thing proper and convenient liberally provided. Let there be a well-situated place for hot-beds, with some building as a tool-house, and (if dry) for keeping bulbs, seeds, and herbs. Those also who garden even upon a small scale will do well to have every needful implement. It is the way to save time and labour, and have work done well.

If water can be introduced, and kept clean with verdant banks around it, it would be found very useful where a garden is large; but let it be as near the centre as possible, as the most convenient situation. It should be fed from a pond in preference to a spring.

Mixed gardening, as comprehending the useful with the sweet, the profitable with the pleasant, has been the subject hitherto; but if the flower garden and the kitchen garden are to be distinct, the case is altered; not so much indeed but that still the kitchen garden should be adorned with a sprinkling of the more ordinary decorations, to skirt the quarters, chiefly those of the most powerful sweet scents, as roses, sweet-briars, and honey-suckles, wall-flowers, stocks, pinks, minionet, &c. in order to counteract the coarser effluvia of vegetables, or of dead leaves, which, however, should not be suffered to annoy.

The flower garden, properly so called, should be rather small than large; and if a seperate portion of ground is appropriated for this, only the choisest flowers should be introduced, and no trouble spared to cultivate them in the best manner. The beds of this garden should be narrow, and consequently the walks numerous; and not more than one-half or two-thirds the width of the beds, except one

principal walk, all round, which may be a little wider. The gravel, or whatever walks are made of, should lie about four inches below the edge. The beds for tulips, hyacinths, anemonies, ranunculuses, &c. may be three and a half or four feet wide, and those for single flowers the same, or only two and a half feet wide in the borders, which was the most usual breadth in the old flower gardens. Let the beds lie rather rounded in the middle, but the walks flat

Figured parterres have got out of fashion, as a taste for open and extensive gardening has prevailed; but when the beds are not too fanciful, but regular in their shapes, and chiefly at right angles, after the Chinese manner, an assemblage of all sorts of flowers, in a fancy spot of about 60 feet square, is a delightful home scource of pleasure, worthy of pursuit. There should be neat edgings of box to these beds, or rather of neat inch-boards, painted lead colour, to keep up the mould. Be sure to keep the box from the very first, as soon as rooted, and always after, as low as possible: clip it twice a year, April and July.

Landscape or *picturesque gardening*, is so much the work of fancy, and so much depends upon the situation, or what the celebrated Mr. Brown used to call the capability of the place, that no precise rules can be laid down concerning it. All, therefore, that can be expected, is a few lose hints, on which the man of taste may improve according to circumstances.

Those, however, who would do much in landscape gardening, should not be forward to trust their own taste altogether. In this business there is no making experiments, but all should be executed, as much as possible, upon certainty. There is a variety of works and decorations in extensive gardening, which injudiciously introduced, might create a wasteful expense. This is an error that ought to be avoided, and most probably would be by those who have been in the habit of studying nature, and the powers of art as her submissive handmaid.

The pleasure we seek in laying out gardens, is now justly founded upon the principles of concealed art, which appears like nature; but still, whether ingenious contrivances, and decorations, (altogether artificial,) should be so entirely laid aside as they are, may deserve to be considered. Gardens were formerly loaded with statues, and great improprieties were committed in placing them, as Neptune in a grove, and Vulcan at a fountain, large figures in small gardens, and small in large, &c. but perhaps the works of the statuary might still be introduced if well excuted, and in proper places. A terrace as a boundary, is now seldom formed; but in some situations, such an eminence might in several respects be agreeable.

If trees are planted injudiciously, the error is a trifle; but if cut down so, the consequence is serious, and has often been sorely lamented; extirpation should therefore be well thought of before it is executed; especially trees about houses, for many dwellings have been thus too hastily exposed, and deprived of comfortable shelter and shade. And why should a taste have prevailed for so sudden a transition, as no sooner out of the house than to arrive in the open country; or why should an extensive garden be thrown as much as possible into a single view, when meeting with new objects in our walks is so agreeable?

Hilly spots that are in view of the house should be planted with firs, as fine-looking trees, and very hardy. Beech does well on high ground, especially if chalky. In low ground, not to mention alders, and that tribe, the birch, and even the oak, should not be forgotten, where the wet does not long stand.

About the house some shady walks ought always be provided, by thick planting, if not of trees, yet of flowering shrubs, and evergreens, of which the laurel will be found the most useful. If there is good room, single trees of the fir kind, at due distances, are admirable ornaments about a house, and clumps of shrubs all of the same kind have a good effect.

Those who have much space of ground to decorate, do well to plant trees and shrubs of every kind, as enlarging the sources of amusement, and affording opportunities for observation; but if the allotment of ground for this purpose is contracted, then, of course, those only should be planted, which by their neat foliage, natural symmetry, and gay flowers, may be truly esteemed ornamental. They should be such as strike the eye of persons in general, though they have nothing of singularity to engage the attention of the curious in plants. It too often happens, that good old sorts of trees, shrubs and flowers, are excluded for new ones; but if the latter are not more elegant, and generally pleasing, the practice is surely not a wise one: in ornamental gardening, great care should be taken, in the choice of what is really handsome, that nothing dull or rambling be introduced.

The walks should always be wide, some inclining to serpentine, and contrived as much as possible upon a level, as walking up and down hills can hardly be called pleasure. That they may be extensive, they should skirt the grounds, and seldom go across them. In small pleasure-grounds the edges of the walks should be regularly planted with flowers, and long ones occasionally so, or with the most dwarf shrubs; and neat sheltered compartments of flowers, (every now and then to be met with) have a pretty effect. If the walks are extended to distant plantations of forest-trees, every opportunity should be taken, to introduce something of the herbaceous flowery kind, which will prove the more pleasing, as found in unexpected situations. The outer walk of pleasure grounds and plantations, should every now and then break into open views of the country, and to parts of the internal space, made pleasing, if not striking, by some work of art, or decoration of nature.

Water should only be introduced where it will run itself clear, or may be easily kept so, as also in full sight; and some fall of it should be contrived, (if possble) for the sake of giving it motion and sound, because a lively scene of this element is always much more pleasant than a dead one. Every spring of water should be made the most of, and though fountains, &c. are out of fashion, something of this kind is agreeable enough. Near some pieces of water, as a cool retreat, it is desirable that there should be something of the summer-house kind; and why not the simple rustic arbour, embowered with the woodbine, the sweetbriar, the jessamine, and the rose? Pole arbours are tied well together with burk or ozier twigs.

Before the design of a rural and extensive garden is put in execution, it ought to be considered, or anticipated, what it will be in twenty or thirty years time; for it of-

ten happens that a design which looks handsome when first planted, and in good proportion, becomes so small and ridiculous in process of time, that there is a necessity either to alter it, or destroy it entirely, and so plant it anew. To proportion the breath of walks, the size of carpets, casting and levelling of grounds, parterres, &c.; the disposal of fountains, statues, vases, dials, and other decorations of magnificience to most advantage, requires a particular address, says Mr. Evelyn, or to speak more emphatically, a prophetic eye; and though the taste is not what it was in Mr. Evelyn's time, yet, perhaps, the only difference is that more skill is requisite.

Landscape gardening depends much on the form of the ground, and therefore to shape that is the first object, Some situations may not need it, and perhaps a little alteration may produce a happy effect in others; therefore great alterations should not be attempted without manifest advantages, as either levelling, or raising ground, is a heavier business than is commonly supposed, both as to time and expense.

Too much plane is to be guarded against; and when it abounds, the eye should be relieved by clumps, or some other agreeable object. Hollows are not easily filled; and eminences mostly are advantageous, in the formation of picturesque scenes, in which the general principle of ornamental gardening consists. This idea has been pressed so far, that it is contended, a gardener should be a studier of landscape paintings. But without an immediate view to pictures, no doubt, grounds may be laid out in a way sufficiently picturesque. That view may be very agreeable in nature, which would not be so in a picture, and the contrary.

Picturesque gardening is effected by a number of means which a true rural genius, and the study of examples, only can produce. These examples may be pictures, but the better instructors will be scenes in nature; and the proper grouping of trees, according to their mode of growth, shades of green, and appearance in autumn, will effect a great deal.

To plant picturesquely, a knowledge of the characteristic differences of trees and shrubs, is evidently a principle qualification. Some trees spread their branches wide, others grow spiral, and some conical: some have a close foliage, othees an open one; and some form regular, others irregular heads, the branches and leaves of which may grow erect, level, or pendant.

The mode of growth in trees, as quick or slow, the time of leafing, and shedding leaf, with the colour of the bark, are all circumstances of consideration in order to produce striking contrasts, and happy assemblages, in the way of ornamental gardening.

To range the shrubs and small trees, so that they mutually set off the beauties, and conceal the blemishes, of each other; to aim at no effects which depend on a nicety for their success, and which the soil, the exposure, or the season of the day, may destroy; to attend more to the groupes than to the individuals; and to consider the whole as a plantation, not as a collection of plants; are the best general rules which can be given concerning them.

In considering the subjects of gardening, ground and wood first present themselves; and water next; which, though not absolutely necessary to a beautiful composition, yet occurs so often, and is so capital a feature, that it is always regretted when wanting; and no large place can be supposed, a little spot can hardly be imagined, in which it may not be agreeable. It accommodates itself to every situation, is the most interesting object in a landscape, and the happiest circumstance in a retired recess: captivates the eye at a distance, invites approach, and is delightful when near: it refreshes an open exposure, it animates a shade, cheers the dreariness of a waste, and enriches the most crowded view. In form, in style, and in extent, it may be made equal to the greatest compositions, or adapted to the least: it may spread in a calm expanse to sooth the tranquility of a spaceful scene; or hurrying along a devious course, add splendour to a gay, and extravagance to a romantic situation. So various are the characters which water can assume, that there is scarcely an idea in which it may not concur, or an impression which it cannot enforce.

On the works of art in gardening, the following passage is pertinent: "Art was carried to excess, when ground, wood, and water, were reduced to mathematical figure, and similarity and order were preferred to freedom and variety. These mischiefs, however, were occasioned, not by the use, but the perversion of art; it excluded, instead of improving upon nature, and thereby destroyed the very end it was called in to promote. Architecture requires symmetry, the objects of nature freedom; and the properties of the one, cannot with justice be transferred to the other. But if by the term art no more is meant than merely design, the dispute is at an end; choice, arrangement, composition, improvement, and preservation, are so many symptoms of art, which may occasionally appear in several parts of a plantation, but ought to be displayed without reserve near the house: nothing there should seem neglected; it is a scene of the most cultivated nature, it ought to be enriched, it ought to be adorned; and design may be avowed in the plan, and even in the execution. Regularity is not excluded: a capital structure may extend its influence beyond its walls; but this power should be exercised only over its immediate apendages. Works of sculpture are not, like buildings, objects familiar in scenes of cultivated nature; but vases, statues, and termini, are usual appendages to a considerable edifice: as such, they may attend the mansion, and trespass a little upon the garden, provided they are not carried so far into it as to lose their connection with the structure."

The cultivation of a garden.—The first object with a view to produce should be, to keep the ground in such a state as will enable it to produce good crops. Good vegetables cannot be had without good manure. Yet raw unwrought dung is not good for a garden. The most economical plan therefore, that can be pursued, is for the first year to make good hot-beds of your dung, and spread it out upon the quarters, and dig it in in autumn and winter. You by this means have a double produce, and the dung is the better.

Dung, however, used in great quantities, and lying in lumps, breeds worms, grubs, and other insects, and causes plants to grow too rampant and rank-flavoured. Carrots it cankers, and it disagrees with many things. On these accounts some persons have been induced to dress their gardens only with rich fresh earth; which, if they do not overcrop, will do very well, being accom-

panied with good tillage: which alone is of much use, and is essential to due cultivation. The method just recommended, of letting dung lie in the state of a hotbed for a time, is good, as it abates the rankness of it.

If the ground is in proper heart, every spot may be contrived to be constantly and successfully cropped. The common gardeners about London, who give high rents for their land, contrive (manuring well) a succession of crops, one under another, very dexterously; and this sort of conduct should be imitated by private persons. Thus a little spot, in skilful and industrious hands, will be much more productive than a greater under contrary management: but when hard worked, the soil will not do without a good deal of manure.

In the occupation of ground, the change of crops will be proper, as each sort of plant draws a somewhat different nourishment: so that after a full crop of one thing, one of another kind may often be immediately sown; but it should be contrived that a wide crop may follow a close one, and contrariwise.

Close crops, as onions, leeks, carrots, &c. are conveniently and neatly cultivated in beds of from four to five feet width, with alleys of from a foot to eighteen inches between them.

The seasons proper for furnishing the ground with every particular vegetable, should be well attended to, that each may be obtained as early as its nature will permit; and of the seeds and plants we use, care must be taken to procure the best of the kind, lest after all the trouble of cultivation, disappointment as to quality should ensue.

Seeds and plants should be adapted as much as possible to the soil and situation which best suit them; for in the same garden some difference will be found, not only as to sun and shelter, but the earth; as some will be richer, some poorer, some deeper, some shallower, and some perhaps, heavier, some lighter, in due attention to which, advantage is to be reaped.

The thinning of seedling crops should be done in time, before the young plants have drawn one another up too much. All plants grow stronger, and ripen better, when the air circulates freely round them, and the sun is not prevented from an immediate influence; an attention to which should be paid from the first appearance of plants breaking ground.

In the pricking and planting out of crops, be sure to do it as early as may be; let every thing be regular, (not sparing to use the line) allowing always room enough for this work; and being thus treated, vegetables will come forwarded, larger, and of a superior flavour. These advantages are seen in all things, but in letuces particularly, which have not half the room allowed them they should have. Over-cropping robs the ground of strength to no purpose, except increasing the dunghill; it makes it also inconvenient to weed, rake, clean up, which in a private garden, at least, it is proper frequently to do.

Shading of new-planted things, particularly flowers, is of much benefit, and that in proportion as the season is sunny, as neglecting this business has frequently proved: as a little water in a cloudy time does plants much good, so when shaded.

Strawberries and cauliflowers are generally watered in a dry season; that is, the strawberries when in bloom, in order to set the fruit, and the cauliflowers when they show fruit, in order to swell the head. In a light soil, this ought particularly to be done. In very dry weather, asparagus seedlings, early turnips, carrots, radishes, and small salads, will need watering. Slips, cuttings, and layers of any kind, will need water. Pots of flowers must have it frequently.

When watering is undertaken, let it be a complete business; *i. e.* to the bottom and extent of the roots; as much as may be. The wetting only the surface of the ground is of little use, and of some certain harm, as it binds and cracks the earth, and so excludes the benefit of showers, dews, air and sun, from entering the soil, and benefiting the roots as they otherwise would do. Wetting the surface of the ground, however, in a summer's evening, makes a cool atmosphere; a dew is formed, which pervades the leaves, and helps to fill their exhausted vessels.

Watering the roots of wall-trees, (if dry weather) when the fruit is setting, is by some thought necessary. The best way to do this effectually, is to make a few holes at some distance from the three with a smooth sharp-pointed stake, the better to let the water down; but this may wound the roots; and should only be practised in a light soil, and very dry season. To young trees only it can however be of use, for the roots of old ones run far and wide; and it is the small fibres of these distant roots, on which the tree chiefly depends for food. Vines should have no water till they are off blossom, (July) and the fruit as big as large pins' heads; and then if the season is very hot and dry, watering the roots twice a week will help the fruit to swell.

As watering is apt to make ground hide-bound and unsightly, let the surface be occasionally stirred and raked, which will make future waterings enter the ground the better; when the ground is hard on the top, the water runs away from its proper place, and half the labour is lost. Many things are impatient of being kept wet about the shanks, and therefore watering should be generally at a little distance.

The quality of water used for refreshing plants is a material thing, and is very various in its nature, according to the peculiar earths and mineral substances that it passes through. Rain water is by far the best, as appears by the verdure and vivacity it gives.

Pond water is next in fitness, and river water follows. Well water is of least account, though local circumstances occasion its use the most. So that in forming a judgment concerning watering, it is not simply to be considered, whether plants should be watered; but whether with well-water, and that too from a pump. Pump-water, if used directly, is so cold in summer, that it is found prejudicial to plants: and great cold so contracts their vessels, that they perform their proper offices with difficulty, and become diseased.*

The management of a garden, as somewhat distinct from the cultivation of it, is an object of consequence; that is, to keep it in such order, that it may not fail in those general impressions of pleasure it is capable of affording, when things are shown in their best manner. A garden may be cultivated so as to be profitable; and yet not conducted so as to be agreeable to walk in, which in a private garden is a circumstance surely to be lamented. The proper appearance of a well managed one is express-

ed by the word neat. Let all be done that can be in order to it.

To be neat, weeding must be industriously followed up, and all litter that is made in working, quickly carried off. The ground also should be frequently stirred and raked between crops, and about the borders, to give all a fresh appearance. There is a pleasantness to the eye in the new-broken earth: and when there are no flowers left in the borders, this gives an air of culture, and is always agreeable. The observation is particularly meant to apply in autumn, that the garden may not become dreary too soon, and so bring on winter before its time. An asparagus-fork is expeditious and useful in this case; but it must be slightly used, lest it disturb the roots of plants too much. Vegetables should not be suffered to rock themselves by wind, so as to form holes round their stems, but be well earthed up or otherwise supported.

Trees and shrubs should be constantly freed from suckers and dangling shoots, and wall trees ought to be regularly kept in order. Grass plats and walks should have their edges occasionally cut, and be mowed as often as there is the least hold for the scythe, for they lose much of their beauty, when the grass gets long; leaves should not be suffered to remain on them, as it stains the grass; and worm-casts should be cleared away. Edgings of all sorts should be kept in good order, as having a singularly neat effect in the appearance of a garden. The dead edgings will sometimes, and the live edgings often, want putting to rights; either cutting, clipping, or making up complete. Where there are no edgings, or but weak ones, let the earth bordering on the walks be kept firm, and now and then worked up by a line in moist weather, beating it smooth with the spade.

Some fruits may need support, by tying their weak branches when they get heavy, to stakes, &c. Rows of raspberries and beans are kept neatly up in their lines, by putting in here and there a stake, and using packthread lengthwise; and thus will they bear better, and be more conveniently gathered. Strawberries of fine heavy sorts, will be preserved from getting dirty and rotten, by tying their stems to little sticks; by this practice the fruit also g ts better ripened, and of a finer flavour. Some persons lay tiles, or moss round the plants, when the fruit is half-grown; but this is not, generally, so well, only it has the advantage in keeping the ground cooler in a hot season. The first and finest scarlets best deserve this trouble.

Flowers should be frequently tied up, and dead and dangling parts trimmed off. Some of them cannot do without support, and many sorts are made more secure and beautiful by proper ties. If this business is neglected, a heavy rain or strong wind may come, and lay all prostrate, especially about the equinoctial seasons; but weakness or their own weight, will often bring flowers down.

The sticks used for flowers, should be of smooth wood, as hazel or sallow, or of neat painted slips of deal, with or without an ornamental head; white is the best colour, on account of its contrast with the leaves.

Decaying flowers should be timely trimmed or removed, and perennials should be regularly freed from the parts running to seed, (except so much as may be wanted) as the production of seeds weakens the root much; sometimes even causing death, and thus many curious perennials have been lost; especially the first year of planting them. To preserve any particular sort therefore, let the stems be cut down as soon as the flowers appear to be going off, or to secure the root in strength, let them not flower at all the first year.

Of Propagation.—Plants are propagated by seeds, suckers, slips, off-sets, divisions, cuttings, layers, and grafts.

By seed is the most general method of propagation, and plants raised any other way are seldom so fine. Those plants from seed which have never been removed, are commonly handsomer, and come forwarder, than those that have been transplanted, provided they were sown in a proper soil and situation.

Commonly speaking, new seed is to be preferred to old, as growing the more luxuriantly, and coming up the surer and quicker. This circumstance induces some private persons to save their own seed that they may not be deceived in buying old for new seed; a trick of trade, it is to be hoped, not practised by every seedsman. Yet a little mixture of old seed is sometimes proper, because the new is perhaps cut off, and the old saved, by being a day or two later in coming up.

If old seed is knowingly sown, some allowance in point of time must be made. Peas and beans of two years old, are by some preferred to new, as not running so much to straw. The same may be said of cucumbers and melons.

As to the age of seeds, at which they may be sown and germinate, it is uncertain, and depends very much how they are preserved. Seeds kept from the air and moisture by being buried deep in the ground will continue a great many years without corruption. Peas and beans will germinate very well at seven years of age; but the seeds of lettuces, onions, kidney-beans, and some others, are not to be depended upon after a year or two; and though generally speaking the smaller seeds are of the least duration, yet their maintenance of vegetative power depends much upon the texture of the seed, with respect to its coat, and the oil it contains, &c.

The saving of seed by private gardeners, is hardly to be recommended. Things running to seed give a garden a rude appearance, often occupying ground that is wanted, and might be used to better purpose: and the case often is, that seeding plants (in private gardens) are neglected in some measure, or destroyed by birds, and come to little at last. Perhaps they are not saved from proper plants. It is a particular business to raise seeds for sale, and, generally, they are best had from those whose province it is to deal in them.

Seeds should be saved from fine forward plants, secured from rocking about when they get tall; guard them against birds, gather them regularly as they ripen, lest they shed and are lost, and keep them dry. Flowers it may be proper to save the seed of, and it is little trouble. It should be a rule for flower-seeds in general to be fresh from year to year; though if kept dry, and from much air, many sorts will grow that are older: curious flower-seeds are kept well in phials: others may be in small drawers, and some hung up, or kept on shelves in their pods.

Seeds may be forwarded for sowing by various ways of procuring a germination before they are put into the

ground. In summer it has been usual to steep both broad and kidney beans in soft water, about twenty-four hours, to forward their growth, and to ascertain their vitality. If the ground is very dry, when these seeds are committed to it, either steeped or not, it is a good way to make drills or trenches to plant them in, watering them well first, and then pressing the seed in a little. Any sort of the broad beans, or even peas, may be forwarded, when ground is not for the present ready, by laying them in damp mould, in a garden-pot; or otherwise, a layer of earth, and a layer of seeds, &c. and they may be put into drills or trenches, with care, when the radicle has got some length, the mould being light, and the work finished by a gentle watering.

The smaller seeds, as carrots, &c. may be prepared for sowing, by simply mixing them in a little moist sand, or fine earth, taking care that they do not lie longer than the usual time of their beginning to sprout; but this practice need only be adopted for seeds that are long in coming up, and then there is some advantage in having them to sow in a state ready to strike immediately on fresh-dug earth.

The season for committing seeds to the ground, should be as early as the nature of the plant to be cultivated will bear; for the forward productions which come without forcing, are the best as to size, flavour, and fruitfulness, if they meet with no material check from weather. It is the proper ambition of gardeners also, to have some of the first of each kind of vegetables and fruits, and thus to vie with others.

Let this direction for early sowing be understood, not only of spring, but autumn crops; that the plants designed for winter use, or to stand for spring, may be strong, and well established in the ground: though for those designed for spring, it is advisable to have two or three different sowings; for lettuces, as an instance, that are forward, will sometimes fail when backward plants shall do well.

To be sure of a crop, and in some things a succession of crops, various sowings should be made through the year, at all times that are not too unnatural as to season; for it is an object in gardening, not only to have early and late productions, but never to be without what may be produced. Every sowing that is made, the early ones in particular, should be noticed in time, whether it is likely to succeed, that the work may be repeated. But a little caution is necessary, that this business be not overdone; for though there may seem to be a sufficient distance of time in sowing for succession crops, yet they tread sometimes upon the heels of one another so fast as to occasion a superfluity. This is often the case in peas and beans, in the height of summer, and especially if a hot season: this caution is the more necessary, where there is no ground to spare, or but few hands to cultivate it; labour with discretion.

Sowings should be generally performed on fresh dug or stirred ground. The digging should therefore be done as near the time designed to sow as can be. If the ground turns up raw, or wet, as early in the spring it is apt to do, a little time must be allowed it to dry, and so also if rain falls first. In this case, seed should be sown as soon as ever the ground may be trampled on not to hang to the feet; for when the soil is too wet, it binds and does harm, especially in heavy ground. It is to be observed, however, that sowing in drills or on beds that are not to be trampled, the moisture of the ground is rather an advantage, provided in the last case, that the ground will admit a rake, and the soil is not too wet to drop somewhat loosely about the seeds.

The proper depth at which seeds should be sown is to be carefully observed; if too deep, they will either rot, or not thrive well; and if too shallow, they are liable to be injuriously affected by frost, wind, drought, or birds; but of the two rather too shallow, than too deep, is best, and this we are taught by nature, whose sowings are mostly superficial.

The smaller the seed the finer should the soil be, and the less also the covering; so that while some, as the seed of celery, is to be but barely covered, others, as peas and beans, may have a depth of two, three, or four inches. But some regard is to be had to the season and soil; in a warm season, and light soil, sow deeper, and the contrary shallower.

The quantity of seed sown is a thing to be attended to with some exactness. Small seeds go a great way, and require a careful hand to distribute them; for though sowing a little too much is a trifle as to the value of seeds, yet to have them come up crowding thick is an evil. To sow evenly as to quantity, is an object of practice worthy of care, as it secures a better crop, and more easily managed in the thinning. If the seed is suspected, sow thicker; poor land will require more seed than rich.

It is not generally advisable to sow several sorts of seed on the same spot, as some persons are accustomed to do. The gardeners about London follow the practice; as profit is their great object, and not neatness or propriety. On the same piece they sow radishes, lettuces, and carrots; the radishes are drawn young for the table, the lettuces to plant out, and a sufficient crop of carrots is left, for carrots should not be very near to grow large: this is as reasonable a combination as any that is made; but still, if not short of ground, each kind separate will be found best. In defence of this mode of culture, it is said, if one crop fails, the others may do, and there is no loss of ground or time; and if all succeed they do very well. Some little things of this sort, indeed, may well be done; as a piece of ground new-planted with horse-radish may be top-cropped with radishes or spinach, &c. A thin crop of onions upon new asparagus-beds, may also take place, drawing them while young from about the plants.

All seeds come up best when moderately pressed with the earth; for if they lie too lightly in contact with it, cold and drought more easily affect them; and when once seeds begin to germinate, they are impatient of both. To trample seeds in is on the whole better than any other pressure. This done, lay all immediately and neatly level with a wide rake, drawing off stones, &c. but do it lightly, to avoid driving in the teeth of the rake, which would remove the seed, and make it come up irregularly.

Propagation by suckers is a mode of culture rather peculiar to trees and shrubs. The things to be observed in this business are, to take them up with some care from the mother plant, so as not to injure its root, nor the sucker's own root, by pulling it up without properly

loosening it first. The earth should be moved aside by a trowel, and then the sucker cut off by a knife, and not with a spade, as is common. Of those hardy things of which there is plenty, this rough way does not signify much as to the sucker, but it may injure the root too much that it comes from. Wherever a root appears barked, the part below should be cut off. If it is desired to succeed well, in propagating by suckers, consider that all young roots are tender: let them be trimmed to form, and planted immediately; or at least let them be covered with earth or laid by the heels, as it is called. Suckers with poor roots, must have their heads reduced the more.

Propagation by slips is of two sorts, either from the root, or stem; and several sorts of flowers and herbs are increased this way. When from the roots, if the whole is not taken up, move the earth carefully aside, and slip off by a pressure of the thumb and finger, and be cautious of hurting the fibres of the slips, planting with fine and good mould about them. Take off slips from the stem carefully by the push of the thumb, and not too many from the same plant, as it is apt to injure the place by tearing off some of the wood. Slips from the stem are to be considered as cuttings, and treated accordingly. They take more certainly, and make better roots, than cuttings.

Offset is a term sometimes applied to slips from fibrous roots; but more properly so from bulbous roots, which put forth many offsets. These are slipped away at the time they are taken up for removal or replanting, and commonly take two or three years before they bear flowers: dispose of them therefore in a nursery, where they may remain undisturbed till they come to a flowering state. Keep them however clean from weeds, and stir the ground a little.

Division of the roots is a way of propagating many sorts of plants. To this end, of course, they must be taken up, and then either carefully pulled, or cut asunder with a sharp instrument, as the case may require. It is not safe, however, to divide such roots into very small pieces, especially if cut, as then they are apt to die; but leave them of a size sufficient not barely to secure life, but to form immediately a handsome head. The general season for thus splitting fibrous-rooted plants is October, but it may be done early in the spring, as February or March.

Cuttings of a variety of woody plants will grow, and many trees and shrubs are propagated this way; but their sap must be of a watery nature, as those plants that are gummy will not strike (or rarely), though ever so much care is bestowed, or time allowed them. The texture of the wood of cuttings must be somewhat soft, as hard-wooded ones will not grow. Cuttings should be rather short than long, and kept steady in the ground. If they are planted where there is any likelihood of their being disturbed, they may be tied to a stick well fastened in the earth.

The season for setting slips and cuttings is for some things summer, as wall-flowers and myrtles; and for most from October to March; but, in general, the sooner the better. It has however been said, that spring is the best time for all, and that the sap should be in motion first. This is at least true of some things: as cuttings of the vitex, or chaste-tree (though hardy), are found to do best in spring; and all cuttings from plants of a delicate nature do so.

Cuttings should be of well ripened wood, and have the earth pressed to them the whole length they are in the ground; *i. e.* from four to six inches. Cut them with a sharp knife slopewise, and plant in a good soil, and in a situation where they have only the morning sun; and keep them cool (not wet) by occasional watering in dry weather.

Laying of branches is a mode of propagation that may be adopted for almost all forest-trees, and several sorts of fruit-trees and shrubs; *i. e.* all that will grow from cuttings, and many that will not. Layers are less rampant, and more fruitful than suckers; and for those who are curious, and find a seminal variety of any tree or shrub that is remarkably different from the original, the only way to have it preserved genuine is to convert it into a stool (by cutting down), and raising plants by layers. They are made of the lower branches of the plant, and must be young and pliable, to bend down without breaking to the depth of four, five, or six inches in the ground, as the soil is light or heavy, at which they must be held securely by good pegs, and if they cannot be brought down sufficiently deep, some earth may be raised up to them.

Let the ground about layers be kept cool by occasional waterings, and laying some moss, turf, litter, or rather small pebbles about them, which will not harbour insects. The part out of ground may be supported erectly by a tie to a stick. It is a good way to slit, with a sharp knife, the part at the peg, as in carnation layers, a little more than an inch; and some prick a few holes about the part, at a joint, with a blunt awl, to help the layer to strike root. For the harder woods, some gardeners make several slits, or chips, in the part layered in the earth, and bind the layer rather tight, just above it, with pliant wire; and soft-wooded layers are sometimes twisted to crack the bark, in order to help the part to strike quickly. Generally layers should be shortened to six or eight inches above the ground; or do it to two eyes, be it more or less above ground.

Where there are no branches low enough to be brought into the ground, and it is not thought good to head down for the production of low shoots or suckers, plants may be layered by fixing a broken pot, or a box, with a slit in the side, to the height necessary to lay in a branch. A branch also, if long enough, may be thrust through the hole of a garden-pot upwards, then filled with earth, and supported by some contrivance, and shaded by some means, and in both cases water frequently. Take care not to injure the buds in drawing through the hole of the pot. By this contrivance rooted plants being procured in pots, may be turned out with the earth about their roots undisturbed. A branch of a vine thus layered in November, may be next year cut off, when the fruit is ripe, brought in the pot to table, and afterwards planted out. For propagation of fruit-trees by grafting, see that article. See also GREENHOUSE, HOT-BEDS, NURSERY, ORCHARD, PLANTING, PRUNING, VEGETABLES, &c.

GARNET, granatus, in natural history, a very beautiful gem of a red colour, with an admixture of bluish.

When pure and free from blemishes, it is little inferior, in appearance, to the oriental ruby, though only of a middle degree of hardness between the sapphire and common crystal. It is found of various sizes, from that of a pin's head to an inch in diameter.

Among our lapidaries and jewellers, genuine garnets are known by different names, according to their different degrees of colour. 1. The garnet, simply so called, is the finest and most valuable kind, being of a very deep blood-red, with a faint admixture of blue. 2. The rock-ruby, a name very improperly given to the garnet, when it is of a very strong but not deep red, and has a fairer cast of the blue; this is a very beautiful gem. 3. The sorane or serain garnet, that of a yet brighter red, approaching to the colour of a native cinnabar, with a faint blue tinge. 4. The almandine, a garnet only a little paler than that called the rock-ruby.

Garnets are very properly distinguished into the oriental and occidental kinds, as being found in Europe as well as the East Indies. The oriental ones are principally brought from Calicut, Cananor, and Cambay; and the European are common in Italy, Hungary, and Bohemia.

Some authors have supposed the deeper-coloured garnet to be the same with the carbuncle of the ancients, from which it really differs; since, on receiving the sun's beams, it never gives so true a fire-colour as the carbuncle.

This stone is found in great plenty in many mountains; it is usually crystallized. The primitive form of its crystals is dodecahedron, whose sides are rhombs with angles of 78° 31′ and 120° 28′. The inclination of the rhombs to each other is 120°. The dodecahedron may be considered as a four-sided prism, terminated by four-sided pyramids. It is divisible into four parallelopipeds, whose sides are rhombs; and each of these may be divided into four tetrahedrons, whose sides are isosceles triangles, equal and similar to either of the halves into which the rhomboidal faces of the dodecahedron are divided by their shorter diagonal. The integrant molecules of garnet are similar tetrahedrons.

The texture of garnet, as Bergman first showed, is foliated. Its fracture commonly conchoidal: causes single refraction: specific gravity 3.75 to 4.188. Colour usually red, often green: brittle: often attracted by the magnet: fusible per se by the blowpipe into a black glass.

Variety 1. Noble garnet. Specific gravity 4 to 4.188: colour deep red inclining to violet: almost always in crystals.

Variety 2. Common garnet. Found in mass and disseminated, sometimes in crystals: fracture uneven, inclining to the conchoidal: specific gravity 3.75 to 4: colour various; shades of green and brown; sometimes hyacinth red and brown red; rarely orange yellow.

A specimen of oriental garnet, analysed by Klaproth, contained

35.75 silica
27.25 alumina
36.00 oxide of iron
0.25 oxide of manganese.
——
99.25

A specimen of red garnet analysed by Vauquelin contained

52.0 silica
20.0 alumina
17.0 oxide of iron
7.7 lime.
——
96.7

And a specimen of black garnet,

43 silica
16 alumina
20 lime
16 oxide of iron
4 water and volat. matter.
—
99.

Pyrop is another species of the garnet. This mineral, which is found in Bohemia, and was formerly distinguished by the name of Bohemian garnet, has been lately separated from the garnet by Werner, and made a distinct species. It is never found crystallized, but only in round or angular fragments, usually small. Colour deep red, which passes to orange when the mineral is exposed to the sun. Very hard. Specific gravity 3.718 to 3.941. Fracture conchoidal, and very brilliant. According to the analysis of Klaproth, it is composed of

40.00 silica
28.50 alumina
10.00 magnesia
3.50 lime
16.50 oxide of iron
0.25 oxide of manganese.

98.75

Garnet, in a ship, is a tackle having a pendant coming down from the mainmast, with a block well seized to the main-stay, just over the hatchway, to which a guy is fixed to keep it steady; and at the other end is a long tackle-block, in which the fall is reeved, that so by it any goods or casks may be hauled and hoisted into or out of the ship. When this garnet is not used, it is fastened along the stay.

GARNISH, in law books, signifies to warn; in which sense, to garnish the heir, is mentioned in stat. 27 Eliz. c. 3.

GARNISHEE, is used for the third person or party in whose hands money is attached within the liberties of the city of London, in the sheriff's court there; and he is so called, because he has had garnishment or warning not to pay the money, but to appear and answer to the plaintiff creditor's suit.

GARNISHMENT, is a warning given to a person for his appearance, for the better furnishing of the cause and court; as where a person is sued for detaining charters or other writings delivered him by the plaintiff, and another person, upon some certain conditions; and therefore he prays that the other person may be warned to plead with the plaintiff, whether the conditions are or are not performed, which is the praying of garnishment; and interpreted to be either a warning of that other, or a furnishing the court with parties sufficient to determine the cause.

GARRISON, in the art of war, a body of forces dis-

posed in a fortress, to defend it against the enemy, or to keep the inhabitants in subjection, or even to be subsisted during the winter season: hence, garrison and winter quarters are sometimes used indifferently, for the same thing, and sometimes they denote different things. In the latter case, a garrison is a place wherein forces are maintained to secure it; and where they keep regular guard, as a frontier town, a citadel, castle, tower, &c. The garrison should always be stronger than the townsmen. Garrison or winter-quarters signify a place where a number of forces are laid up in the winter season, without keeping the regular guard.

Garrison Guns, such as are mounted and used in a garrison, consisting of the following weights, viz. the 42, 32, 24, 18, 12, 9, and 6 pounders; being made either of brass or iron.

TABLE

Of the Weight and Dimensions of Garrison Guns.

Brass Garrison Guns.						Iron Garrison Guns.

GARTER, *order of the*, a military order of knighthood, the most noble and ancient of any lay order in the world, instituted by king Edward III. This order consists of twenty-six knights companions, generally princes and peers, whereof the king of England is the sovereign or chief. They are a college or corporation, having a great and little seal. Their officers are a prelate, chancellor, register, king at arms, and usher of the black rod. They have also a dean with twelve canons and petty canons, vergers, and twenty-six pensioners, or poor knights. The prelate is the head. This office is vested in the bishop of Winchester, and has ever been so. Next to the prelate is the chancellor, which office is vested in the bishop of Salisbury, who keeps the seals, &c. The next is the register, who by his oath is to enter upon the registry, the scrutinies, elections, penalties, and other acts of the order, with all fidelity. The fourth officer is garter, and king at arms, being two distinct offices united in one person. Garter carries the rod and sceptre at the feast of St. George, the protector of this order, when the sovereign is present. He notifies the elections of new knights, attends the solemnity of their installations, carries the garter to the foreign princes, &c. He is the principal officer within the college of arms, and chief of the heralds.

All these officers, except the prelate, have fees and pensions. The college of the order is seated in the castle of Windsor, with the chapel of St. George, and the chapter-house, erected by the founder for that purpose. The habit and ensign of the order are a garter, mantle, cap, george, and collar. The first four were assigned the knights-companions by the founder; and the george and collar by Henry VIII. The garter challenges pre-eminence over all the other parts of the dress, for from it the noble order is denominated; and it is the first part of the habit presented to foreign princes, and absent knights, who, and all other knights elect, are therewith first adorned; and it is of so great honour and grandeur, that by the bare investitute with this noble ensign, the knights are esteemed companions of the greatest military order in the world. It is worn on the left leg between the knee and calf, and is enamelled with this motto, *honi soit qui mal y pense*, *i. e.* "shame to him that evil thinks hereof." The meaning of which is, that king Edward who laid claim to the kingdom of France, retorted shame and defiance upon him that should dare to think amiss of the just enterprize he had undertaken, for recovering his lawful right to that crown, and that the bravery of those knights whom he had elected into this order, was such as would enable him to maintain the quarrel against those that thought ill of it.

The mantle is the chief of those vestments made use of upon all solemn occasions. The colour of the mantle is by the statutes appointed to be blue. The length of the train of the mantle only distinguishes the sovereign from the knights-companions. To the collar of the mantle is fixed a pair of long strings, anciently woven with blue silk only, but now twisted round, and made of Venice gold and silk, of the colour of the robe, with knobs, or buttons, and tassels at the end. The left shoulder of the mantle has from the institution been adorned with a large garter, with the device *honi soit*, &c. within this is the cross of the order, which was ordained to be worn at all times by king Charles I. At length the star was introduced, being a sort of cross irradiated with beams of silver.

The collar is appointed to be composed of pieces of gold in fashion of garters, the ground enamelled blue, and the motto gold. The manner of electing a knight-companion into this most noble order, and the ceremonies of investure, are as follow. When the sovereign desires to elect a companion of the garter, the chancellor belonging to this order draws up the letters, which passing both under the sovereign's sign manual and signet of the order, are sent to the person by garter principal king at arms, and are in this manner, or to the same effect: "We with the companions of our most noble order of the garter, assembled in chapter, holden this present day at our castle at Windsor, considering the virtuous fidelity you have shown, and the honourable exploits you have done in our service, by vindicating and maintaining our right, &c. have elected and chosen you one of the companions of our order. Therefore we require you to make your speedy repair unto us, to receive the ensigns thereof, and be ready for your installation upon upon the — day of this present month, &c."

The garter, which is of blue velvet bordered with fine gold wire, having commonly the letters of the motto of the same, is, at the time of election, buckled upon the left leg, by two of the senior companions, who receive it

from the sovereign, to whom it was presented upon a velvet cushion by garter king at arms, with the usual reverence, whilst the chancellor reads the following admonition, enjoined by the statutes: "To the honour of God omnipotent, and in memorial of the blessed martyr St. George, tie about thy leg, for thy renown, this noble garter; wear it as the symbol of the most illustrious order, never to be forgotten or laid aside; that thereby thou mayest be admonished to be courageous, and having undertaken a just war in which thou shalt be engaged, thou mayest stand firm, valiantly fight, and successively conquer."

The princely garter being thus buckled on, and the words of its signification pronounced, the knight elect is brought before the sovereign, who puts about his neck, kneeling, a sky-coloured ribbon, to which is appendant, wrought in gold within the garter, the image of St. George on horseback, with his sword drawn, encountering with the dragon. In the mean time, the chancellor reads the following admonition: "Wear this ribbon about thy neck, adorned with the image of the blessed martyr and soldier of Christ, St. George, by whose imitation provoked, thou mayest so overpass both prosperous and adverse adventures, that having stoutly vanquished thine enemies both of body and soul, thou mayest not only receive the praise of this transient combat, but be crowned with the palm of eternal victory."

Then the knight elected kisses the sovereign's hand, thanks his majesty for the great honour done him, rises up, and salutes all the companions severally, who return their congratulations.

Since the institution of this order, there have been eight emperors, and twenty-eight kings, besides numerous sovereign princes, enrolled as companions. Its origin is somewhat differently related: the common account is, that it was erected in honour of a garter of the countess of Salisbury, which she dropped dancing with king Edward, and which that prince picked up; but our best antiquarians think it was instituted on account of the victory over the French at Cressy, where the king ordered his garter to be displayed as a signal of the battle.

GAS, among chemists, a term made use of to denote all the aerial and permanently elastic fluids, except the atmospheric air. See Air.

GASTEROSTEUS, Stickleback, in ichthyology, a fish of the order thoracici. The generic character is, body somewhat lengthened: dorsal spines distinct: ventral fins spiny: abdomen carinated or shielded on the side, and bony beneath. There are eleven species: the following are the principal:

1. Gasterosteus aculeatus, common stickleback. This minute fish is an almost universal inhabitant of ponds, rivers, and marshes, occurring sometimes even in salt or brackish waters. When in its full perfection of colour it is highly beautiful; the gills and abdomen being of a bright red, the back a fine olive-green, and the sides silvery. It is chiefly in the early part of summer that it appears thus decorated; the colours in a great degree fading as the season advances. The general length of this species is about two inches, but it sometimes arrives to the length of three: the ventral fins consist merely of a very strong and serrated spine on each side, accompanied by a single short ray.

The stickleback or banstickle is a fish of an extremely active and vigorous nature, swimming rapidly, and preying on the smaller kind of water-insects and worms, as well as on the spawn of other fishes, and is from this circumstance considered as highly prejudicial to fish-ponds. In the Philosophical Transactions we find some observations relative to the natural history of this fish by Mr. Henry Baker, who informs us that it will spring occasionally to the perpendicular height of not less than a foot out of the water, and to a much greater space in an oblique direction, when wishing to get over stones or other obstacles. "It is scarcely to be conceived," says this writer, "what damage these little fish do, and how greatly detrimental they are to the increase of all the fish in general among which they live; for it is with the utmost industry, sagacity, and greediness, that they seek out and destroy all the young fry that come in their way, which are pursued with the utmost eagerness, and swallowed down without distinction, provided they are not too large: and in proof of this I must assert that a banstickle which I kept for some time did on the 4th of May devour in five hours time seventy-four young dace, which were about a quarter of an inch long, and of the thickness of a horsehair: two days after, it swallowed sixty-two, and would, I am persuaded, have eaten as many every day, could I have procured them for it."

The stickleback is sometimes observed to swarm in prodigious multitudes in some particular parts of Europe. We are told by Mr. Pennant that at Spalding in Lincolnshire, there are, once in seven years, amazing shoals, which appear in the Welland, and come up the river in the form of a vast column: they are supposed to be the multitudes that have been washed out of the fens by the floods of several years, and collected in some deep hole, till, overcharged with numbers, they are periodically obliged to attempt change of place; the quantity is so great that a man employed to take them has got for a considerable time four shillings a day by selling them at the rate of a half-penny per bushel.

2. Gasterosteus spinachia, fifteen-spined stickleback, is much larger than the preceding species, and of a much more slender form; general length from five to six or seven inches; head of a produced and somewhat tubular shape; hinder parts very slender towards the tail; lateral line broad, and composed of a series of small dusky laminæ or scuta; dorsal spines concealed at pleasure in a longitudinal channel; ventral fins each composed of two spines; the first long, the next short: native of the European seas, frequenting shallow places, and preying on marine insects, and the spawn of other fishes; sometimes seen in vast numbers about the coasts of Holland, &c. and occasionally used, like the common stickleback, for the purpose of manuring land, as well as for the preparation of oil for lamps, &c.

GASTRIC Juice, among physicians, a thin, pellucid, spumous, and saltish liquor, which continually distils from the glands of the stomach, for the dilution of the food. See Digestion.

GASTROBRANCHUS, in ichthyology, a genus of fishes of the order chondropterigius: the generic character is, body eel-shaped; mouth beneath, with numerous pectinate teeth; spiracles two, beneath the abdomen.

1. Gastrobranchus cæcus, blind gastrobranchus. The

fish which constitutes this genus has long since been described by Linnæus and others under the title of myxine glutinosa, and considered as belonging to the tribe of vermes, in which situation it ranks in the latest editions of the Systema Naturæ. Dr. Bloch, however, from accurate examination both of its external and internal structure, has very justly considered it as a legitimate cartilaginous fish. The usual length of the European specimens is from four to six inches, but in the Indian ocean it appears to arrive at a far superior size, nearly equalling in this respect the common eel. In its general appearance it bears a near resemblance to the lampreys, with which by Kalm, its first describer, it has been associated. It is remarkable for the total want of eyes, not the least vestige of any such organs being discoverable by the most attentive examination: the mouth, which is situated beneath, as in the lampreys, is of an oblong form; on each side are two beards or cirri, and on the upper part four; in front of the top of the head is a small spout-hole, furnished with a valve, by which it can at pleasure be closed; the teeth, which are situated very deep in the mouth, and are of an orange-colour, as in the lamprey, are disposed on each side into a double row, in form of a pectinated bone; each upper row consisting of nine and each lower row of eight teeth; and in the middle of the roof of the mouth is a single, sharp-pointed, and curved tooth; no nostrils are discoverable; the body is destitute of scales, lateral line, and every kind of fin, except that which forms the tail; this fin is shallow, and commencing at the lower part of the back, runs round the extremity of the body, and is continued beneath as far as the vent; the extremity of the body, where it is surrounded by the caudal fin, is taper or pointed; beneath the body, from head to tail, runs a double row of pretty conspicuous, equidistant pores, through which on pressure, exudes a viscid fluid, and at somewhat more than a third of the animal from the head, are situated beneath the body, the two spiracula, which consist of a pair of oval apertures.

The manners of this fish are represented as highly singular; it is said to enter into the bodies of such fishes as it happens to find on the fishermen's hooks, and which consequently have not the power of escaping its attack, and by gnawing its way through the skin to devour all the internal parts, leaving only the bones and the skin remaining. Another particularity in this animal consists in its uncommonly glutinous nature; if put into a large vessel of sea-water, it is said in a very short space to render the whole so glutinous as easily to be drawn out into the form of threads; when taken out of water the gastro-branchus is said to be incapable of living more than three or four hours. It is an inhabitant of the northern seas, and appears also to occur in those of the southern hemisphere, where, as before mentioned, it arrives at a much larger size than in the northern regions.

2. Dombeyan gastrobranchus. Size much larger than the European specimens of the gastrobranchus cæcus: head rounded, and broader than the body; on the upper lip four beards; number of those on the lower uncertain, the specimen being described in a dried state; teeth pointed, compressed, triangular, and disposed in two circular ranges, the exterior of which is composed of twenty-two, and the interior of fourteen teeth; a single tooth longer than the rest, and of a curved form in the roof of the mouth, as in the European species; eyes and nostrils imperceptible; colour uncertain; tail rounded at the extremity, and terminated by a very shallow fin united with the anal. Native of the South American seas; observed by Mons. Dombey, and described by Cepede from the dried skin in the Paris museum.

GASTROGRAPHY, in surgery, the operation of sowing up wounds of the abdomen. See SURGERY.

GATE, in a military sense, is made of strong planks, with iron bars, to oppose an enemy. They are generally made in the middle of the curtin, from whence they are seen, and defended by the two flanks of the bastions. They should be covered with a good ravelin, that they may not be seen or enfiladed by the enemy. These gates, belonging to a fortified place, are passages through the rampart, which may be shut and opened by means of doors and a portcullis. They are either private or public.

Private gates are those passages by which the troops can go out of the town unseen by the enemy, when they pass to and from the relief of the duty in the outworks, or on any other occasion which is to be concealed from the besiegers.

Public gates are those passages through the middle of such curtins, to which the great roads of public ways lead. The dimensions of these are usually about 13 or 14 feet high, and 9 or 10 feet wide, continued through the rampart, with proper recesses for foot-passengers to stand in, out of the way of wheel-carriages.

GAVELKIND, a custom principally to be found among the men of Kent, and supposed to be one of the effects of the gallant struggles they made to preserve their liberty, though it is sometimes found in other parts of the kingdom. This tenure has various consequences: the principal are, 1. The tenant can alien his estate by feoffment at the age of 15. 2. The estate does not escheat in case of an attainder and execution for felony. 3. In most places he had a power of devising his estate by will, before the statute was made to restrain him. 4. The lands descend to all the sons equally together, according to the ancient course of descent in England, and not according to primogeniture.

GAVELET, in law, an ancient and special cessavit used in Kent, where the custom of gavelkind continues, by which the tenant, if he withdraws his rent and services due to the lord, forfeits his lands and tenements.

The process of the gavelet is thus. The lord is first to seek by the steward of his court, from three weeks to three weeks, to find some distress upon the tenement, till the fourth court; and if at that time he find none, at this fourth court it is awarded, that he take the tenement in his hand in name of a distress, and keep it a year and a day without manuring; within which time, if the tenant pays his arrears, and make reasonable amends for the withholding, he shall have and enjoy his tenement as before: if he come not before the year and day be past, the lord is to go to the next county-court with witnesses of what had passed at his own court, and pronounce there his process, to have further witnesses; and then by the award of his own court, he shall enter and manure the tenement as his own; so that if the tenant desired afterwards to have and hold it as before, he must

agree with the lord; according to this old saying, "Has he not since any thing given, or any thing paid, then let him pay five pound for his were, e'er he become healder again." Other copies have the first part with some variation; "Let him nine times pay, and nine times repay."

Gavelet, in London, is a writ used in the hustings, given to lords of rents in the city of London. Here the parties, tenant and demandant, appear by scire facias, to show cause why the one should not have his tenement again on payment of his rent, or the other recover lands on default thereof.

GAUGE-POINT, of a solid measure, the diameter of a circle, whose area is equal to the solid content of the same measure. Thus the solidity of a wine-gallon being 231 cubic inches, if you conceive a circle to contain so many inches, the diameter of it will be 17.15; and that will be the gauge-point of wine-measure. And of an ale-gallon, containing 282 cubic inches, by the same rule, the gauge-point for ale-measure will be found to be 19.15. After the same manner, may the gauge-point of any foreign measure be obtained; and hence may be drawn this consequence, that when the diameter of a cylinder, in inches, is equal to the gauge-point of any measure, given likewise in inches, every inch in length thereof will contain an integer of the same measure, *e. g.* in a cylinder whose diameter is 17.15 inches, every inch in height contains one entire gallon in wine-measure; and in another, whose diameter is 18.95 inches, every inch in length contains one ale-gallon.

GAUGER, a king's officer, who is appointed to examine all tuns, pipes, hogsheads, and barrels of wine, beer, ale, oil, honey, &c. and give them a mark of allowance, before they are sold in any place within the extent of his office.

There are divers statutes that mention this officer and his office; as by 27 Ed. III. c. 8. all wines, &c. imported are to be gauged by the king's gaugers, or their deputies, otherwise they shall be forfeited, or their value; and on default of the gauger, that he be not ready to do his office when required, or that he defrauds in doing his office to the damage of the buyer or seller, he shall pay the party grieved his treble damage, lose his office, be punished by imprisonment, and be ransomed at the king's will: and in case less is found in the tun or pipe than ought to be, the value of as much as shall lack, shall be deducted in the payment.

Every gauger shall truly, within the limits of his office, gauge all tuns, butts, pipes, tierces, puncheons, tertians, hogsheads, barrels, and runlets; and mark on the head of every vessel the contents, upon pain of forfeiting to the party to whose use the wine, &c. shall be sold, four times the value of that which the vessel marked shall lack of its content: the same forfeiture shall be recovered by an original writ, &c. and every person selling the wine, &c. in the vessel marked, shall allow of the price, the value of gauge, or default of filling, upon pain of forfeiture to the buyer, of double the value, to be recovered with costs as before. No brewer shall put to sale any beer or ale in vessels brought from beyond the sea, within the city of London, or suburbs of the same, or within two miles compass without the suburbs, before the same is gauged, and the true content of every such vessel set upon the same, by the gallon appointed for beer and ale, according to the standard, by the master and wardens of the coopers of London.

GAUGING, the art or act of measuring the capacities or contents of all kinds of vessels, and determining the quantities of fluids or other matters contained therein.

To gauge any vessel, or to find the quantity of liquor it can contain,

Find how many solid inches will fill the cavity of the vessel, and divide these by the number of solid inches which make a pint or gallon; the quotient is the content of the vessel in pints or gallons.

TABLE *of Cubic Inches in several Measures.*

282	Cubic inches	= 1 English ale gallon
231	Ditto	= 1 English wine gallon
268.8	Ditto	= 1 English corn gallon
2150.4	Ditto	= 1 English corn or malt bushel.

From these divisors, multipliers may be found thus: Divide 1 by any number in this table, the quotient is a constant multiplier, by which the content of any vessel in cubic inches being multiplied, the product is its content in that measure for which the multiplier was found.

TABLE *of Divisors and Multipliers.*

282	.003546 ale gallons
231	.004329 wine gallons
268.8	.0037202 corn gallons
2150.42	.00046502 malt bushels.

In gauging vessels, the dimensions are always taken in inches and decimals of an inch.

Ex. 1. Suppose a vessel in form of a parallelopiped, the length of its base 27 inches, breadth $16\frac{1}{2}$ inches, and the depth of the vessel $32\frac{1}{4}$ inches; required the content in English ale gallons?

$$27 \times 16.5 \times 32.25 = 14367.375 \text{ cubic inches.}$$

If you divide 14367.375 by 282, or multiply them by 003546, the result will be the content of the vessel in English ale gallons, viz. 50.946.

In the same manner, the content of any vessel may be found; but those who practice gauging proceed thus:

In any vessel equally wide from top to bottom, they compute the area of its base in square inches; and, by dividing or multiplying these by the numbers in the tables, get what they call the area in gallons, (that is, the number of gallons which the vessel contains when the liquid is only one inch deep), which multiplied by the depth of the liquid, gives the quantity contained in the vessel.

Ex. 2. Suppose a trough, or cistern, in form of a right-angled parallelopiped, its base 27 inches long, and $16\frac{1}{2}$ inches wide, and the height of the vessel $32\frac{1}{2}$ inches, but the depth of liquor only 20 inches; required its content in English ale gallons? *Ans.* 31.594.

$27 \times 16.5 \times .003546 = 1.579743$, the area of the base in gallons, which multiplied by 20, produces 31.594 ale gallons.

Ex. 3. Suppose a cylindric vessel hath the diameter of its base 20 inches, and its height 30 inches; required the content in wine gallons? *Ans.* 40.8.

$$20 \times 20 \times .7854 \times 30 \times .004329 = 40.8.$$

Suppose a tub having circular bases, the diameter of the mouth is 60 inches, and the diameter of the bottom is 36 inches, and the perpendicular depth from top to bot-

tom is 30 inches; required its content in English ale gallons?

This vessel is to be considered as the frustum of a cone; and, on this supposition its content will be 55417.8 cubic inches; which, by reduction, is 196.5 English ale gallons.

The calculation is tedious by common arithmetic, but may be easily performed by logarithms; thus, To twice the logarithm of the diameter of one base add the logarithm of .7854, the sum is the logarithm of the area of that base. Do the same for the area of the other base, and find the numbers answering to each. Then add the logarithms of the areas of the two bases, and take half of the sum, and find the number answering thereto. Add the areas of the two bases, and the last-found number, and multiply the sum by one-third part of the depth, the product is the content in cubic inches.

Operation for the last Example.

	Log.		Log.
Diameter 60	1.7781513	Diameter 36	1.5563025
	1.7781513		1.5563025
7854	9.8950909	.7854	9.8950909
2827.44	3.4513935	1017.8784 =	3.0076959
1017.8784		2827.44	3.4513935
1696.464			2)6.4590894
5541.7824			
Mult. by 10		1696.464 =	3.2295447
55417.824 Ans.			

The content of any vessel of this form may be found with less trouble by this rule:

To the product of the diameters of the two bases, add one-third part of the square of their difference; the sum is the square of a mean diameter; which being multiplied by .7854, and the product by the depth of the vessel, gives the content in cubic inches.

Exam. Let the diameter of the greater base be 60, and of the lesser base 57.6, and the perpendicular height of the tub 29.976 inches; required its content? *Ans.* 81410.3 cubic inches.

To Gauge a CASK.—Casks are distinguished into the following four varieties:

1. Such as resemble the middle frustum of a spheroid.
2. Such as resemble the middle frustum of a parabolic spindle.
3. Such as being cut through in the middle, the two parts are parabolic conoids.
4. Such as being cut through in the middle, the parts are the lower frustums of two equal cones.

Measure the head and bung diameters, and the length of the cask in inches; and then,

1. If the staves are very much curved, the cask is supposed to be the middle zone, or frustum of a spheroid: and its content may be found by this rule:

To twice the square of the bung diameter, add the square of the head diameter; multiply the sum by the length of the cask, and divide the product by 3.8197, the the quotient is the content in cubic inches.

Exam. Suppose there is a spheroidal cask, its bung diameter = 31.5 inches, head diameter = 24.5 inches, and the length of cask = 42 inches; required its content in English ale gallons?

Ans. 100.78.

2. If the staves of a cask are less curved than was supposed in the last article, the cask is taken for the middle frustum, or zone, of a parabolic spindle; and its content is computed by this rule:

To twice the square of the bung diameter, add the square of the head diameter, and from the sum subtract four-tenths of the square of the difference of the diameters; divide the remainder by 3.8197, and multiply the quotient by the length of the cask; the product is its content in cubic inches.

Exam. Let the bung diameter = 34 inches, the head diameter = 30, and the length of the cask = 40 inches; what is its content in English ale gallons? *Ans.* 119.039.

3. When the staves of a cask are very little curved, the cask is supposed to consist of the two lower frustums of two equal parabolic conoids, their greatest bases joined together in the middle of the cask; the content of such a vessel may be found by this rule:

To the spuare of the bung diameter, add the square of the head diameter; multiply the sum by .3927, and the product by the length of the cask; the last product is the content in cubic inches.

Exam. Let the bung diameter of such a cask = 32 inches, the head diameter = 29, and the length of the cask = 42 inches; required its content in cubic inches and ale gallons?

Ans. 30760.191 cubic inches, or 109.07 ale gallons.

4. If the staves of a cask are straight between the bung and the ends of the cask, the vessel is supposed to consist of the two lower frustums of equal cones; and its content is found by this rule:

To the sum of the square of the head and bung diameters add their product; multiply the sum by the length of the cask, and divide the product by 3.8197; the quotient is the content in cubic inches.

Exam. Required the content of a cask in ale gallons, its bung diameter being 32 inches, its head diameter 24 inches, and the length 40 inches? *Ans.* 87.93.

By these rules, the content of any cask may be found, it being known to which of the four varieties the cask belongs; but in common practice, a mean diameter, whereby the cask is reduced to a cylinder in either variety, is found thus:

5. Multiply the difference between the bung and head diameters by .7 for the spheroid, by .65 for the spindle, by .6 for the conoids, and by .55 for the cones; add the product to the head diameter; the sum is a mean diameter; or the diameter of the base of a cylinder equal to the cask, their lengths being the same. The mean diameter being squared and multiplied by .7854, and the product by the length of the cask, gives the content in cubic inches, which may be reduced to gallons by the table.

Ex. Suppose the bung diameter is 30 inches, the bead diameter 20 inches, and the length of the cask 40 inches, required its content in ale gallons according to each variety.

DIFFERENCE *of* BUNG *and* HEAD DIAMETERS *is* 10 INCHES. M. D.

$10 \times .7 = 7.$ and $20 + 7. = 27.$ for the spheroid,

$10 \times .65 = 6.5$ and $20 + 6.5 = 26.5$ for the spindle.
$10 \times .6 = 6.$ and $20 + 6. = 26.$ for the conoids.
$10 \times .55 = 5.5$ and $20 + 5.5 = 25.5$ for the cones.

For the CONTENT *in* ALE GALLONS.

$27. \times 27. \times .7854 \times 40 \times .003546 = 81.21$ spheroid
$26.5 \times 26.5 \times .7854 \times 40 \times .003546 = 78.23$ spindle
$26. \times 26. \times .7854 \times 40 \times .003546 = 75.3$ conoids
$25.5 \times 25.5 \times .7854 \times 40 \times .003546 = 72.43$ cones.

Mr. Ward, who had much practice in gauging, says, he never gauged a cask that contained so much as the first variety makes it; and therefore, recommends the 2d and 3d varieties as the best general rules for gauging casks.

The following rule is given by Dr. Hutton, which is not only general for all casks that are commonly met with, but easily to be worked, and accurate in its application.

General Rule. Add into one sum,
39 times the square of the bung diameter,
25 times the square of the head diameter, and
26 times the product of those diameters;
multiply the sum by the length of the cask, and the product by the number .00034; then this last product divided by 9 will give the wine gallons, and divided by 11 will give the ale gallons.

Or, $\overline{39B^2 + 25H^2 + 26BH} \times \frac{L}{114}$ is the content in inches; which being divided by 231 for wine gallons, or by 282 for ale gallons, will be the content.

For Ex. If the length of a cask be 40 inches, the bung diameter 32, and the head diameter 24,

Here	$32^2 \times 39 =$	39936
and	$24^2 \times 25 =$	14400
and	$32 \times 24 \times 26 =$	19968
	the sum	74304
	multiplied by	40
	and divid. by 114)	2972160
	gives	26071 cubic inches;

this divided by 231 gives 112 wine gallons,
or divided by 282 gives 92 ale gallons.

But gauging, as now practised, is chiefly done by means of instruments called gauging rods or rulers, which do the business at once, and answer the question without so much calculation, which is no inconsiderable addition both to the ease and despatch of the work, though it is not so much to be depended on.

The method of gauging which is mostly used, is by the four feet guaging-rod and Everard's sliding-rule; the description and uses of both are as follows:

The four-feet gauging-rod (Plate LXIV. Miscel. fig. 101) is usually made of box, and consists of four rules, each a foot long, and about three-eighths of an inch square, joined together by three brass joints; by which means the rod is rendered four feet long when the four rules are opened, and but one foot when all are folded together. On the first face of this rod, marked 4, are placed two diagonal lines, one for beer and the other for wine; by means of which the content of any common vessel in beer or wine gallons, may be readily found, by putting the brased end of the guaging-rod into the bung-hole of the cask, with the diagonal lines upwards, and thrusting this brased end to the meeting of the head and staves; then with chalk make a mark at the middle of the bung-hole of the vessel, and also on the diagonal lines of the rod, right against or over one another, when the brased end is thrust home to the head and staves; then turn the guaging-rod to the other end of the vessel, and thrust the brased end home to the end as before. Lastly, see if the mark made on the gauging-rod, come even with the mark made on the bung-hole, when the rod was thrust to the other end, which if it be, the mark made on the diagonal lines will, on the same lines, show the whole content of the cask in beer or wine gallons. If the mark made on the bung-hole be not right against that made on the rod, when you put it the other way, then right against the mark made on the bung-hole, make another on the diognal lines; and the divisior on the diagonal line, between the two chalks, will show the whole content of the vessel in beer or wine gallons.

Thus, if the diagonal line of a vessel be 284-10 inches, its content in beer-gallons will be nearly 51, and in wine, gallons 62.

If a vessel be open as a half-barrel, tun, or copper, and the measure from the middle on one side to the head and staves be 38 inches, the diagonal line gives 122 beer-gallons; half of which, viz. 61, is the content of the half-tub.

If you have a large vessel, as a tun or copper, and the diagonal line taken by a long rule be 70 inches, then every inch at the beginning-end of the diagonal line call 10 inches; thus 10 inches become 100 inches, and every tenth of a gallon call 100 gallons, and every whole gallon call 1000 gallons.

Example. At 44.8 inches on the diagonal beer line is 200 gallons; so that 4 inches 48 parts, now called 44 inches eight-tenths, is just two-tenths of a gallon, now called 200 gallons; so also, if the diagonal line be 76 inches and seven-tenths, a close cask of such diagonal will hold 1000 beer-gallons; but an open cask but half so much, viz. 500 beer-gallons.

On the second face, 5, are a line of inches and the gauge-line, which is a line expressing the areas of circles (whose diameters are the correspondent inches) in ale gallons; at the beginning is written ale-area. Thus, to find the content of any cylindrical vessel in ale-gallons, seek the diameter of the vessel in inches, and just against it, on the gauge-line, is the quantity of ale-gallons contained at one inch deep; this multiplied by the length of the cylinder, will give its contents in ale-gallons.

On the third face, 6, are three scales of lines; the first, at the end of which is written hogshead, is for finding how many gallons there are in a hogshead, when it is not full, lying with its axis parallel to the horison. The second line, at the end of which is written B. L. is for the same purpose. The third is to find how much liquor is wanting to fill up a butt, when it is standing; at the end of it is wrote B. S. signifying, butt standing.

Half-way the fourth face of the gauging-rod, 7, there are three scales of lines, to find the wants in a firkin, kilderkin, and barrel, lying with their areas parallel to the horizon. They are distinguished by the letters F. K. B. signifying a firkin, kilderkin, and barrel.

Use of the gauge-line.—To find the content of any cylindrical vessel in ale-gallons, seek the diameter of the vessel in inches, and just against it on the gauge-line is the quantity of ale-gallons contained in one inch deep; this

multiplied by the length of the cylinder will give its content in ale-gallons. For example, suppose the length of the vessel 32.06, and the diameter of its base 25 inches, to find what is the content in ale-gallons? Right against 25 inches on the gauge-line is one gallon and .745 of a gallon; which multiplied by 32.06, the length, gives 55.9447 gallons for the content of the vessel. The bung diameter of a hogshead being 25 inches, the head diameter 22 inches, and the length 32.06 inches, to find the quantity of ale-gallons contained in it? Seek 25, the bung diameter, on the line of inches, and right against it on the gauge-line you will find 1.745: take one-third of it, which is .580, and set it down twice; seek 22 inches in the head diameter, and against it you will find on the gauge-line 1.356; one-third of which added to twice .580 gives 1.6096; which multiplied by the length 32.06, the product will be 51.6, the content in ale-gallons.

Everard's sliding-rule is principally used in gauging, being ordinarily made of box, a foot long, an inch broad, and 1 6-10th inch thick, with two small scales to slide in it, which may be drawn out, one towards the right hand, and the other towards the left, till the whole be 3 feet long.

To gauge malt.—1. If the malt lies on the floor in a rectangular form, multiply the length by the breadth, and the product by the depth, all taken in inches; the product is the number of cubic inches in the quantity; which being divided by 2150.42, the quotient is the number of bushels.

The same rule serves for finding the quantity of malt contained in any vessel in form of a parallelopipedon.

Exam. Suppose a quantity of malt on the floor, 288 inches long, 144 inches broad, and $9\frac{1}{2}$ inches deep; required the number of bushels?

Ans. 183.21.

2. When malt is in a cistern, or any vessel, the content of the vessel is to be found in cubic inches, by some of the former rules, and then divided by 2150.42, the quotient is the number of bushels.

3. To find the solidity of any irregular solid.

Put the irregular body into any vessel, and fill it with water; take out the body, and the water will fall lower, and leave a part of the vessel empty, equal to the solidity of the body to be measured; then measure so much water by a vessel of a known capacity as shall fill up the empty space; and the number of cubic inches in that space, and consequently in the irregular body, will be known.

GAULTHERIA, a genus of the class and order decandria monogynia. The cal. outer, 2-leaved, inner 5-cleft; cor. ovate; nect. with 10 dagger-points; caps. 5-celled, covered with the inner calyx, now become a berry. There is one species, a small but beautiful shrub of Canada.

GAURA, a genus of the class and order octandria monogynia. The calyx is four-cleft, tubulous; corolla four-petalled, rising towards the upper side; nect. inferior, one-seeded, four-cornered. There is one species, a biennial plant of North America.

GAURS, an ancient sect of the magicians in Persia. They have a suburb at Ispahan, which is called Gaurabad, or the town of the gaurs, where they are employed only in the meanest and vilest drudgery; but they chiefly abound in Kerman, the barrenest province in all Persia, where the Mahometans suffer them to live with some freedom, and in the full exercise of their religion. Some years ago many of them fled into India, where their posterity remain. They are a poor harmless sort of people, zealous in their superstition, rigorous in their morals, and exact in their dealings; they profess the worship of one God alone, the belief of a resurrection and a future judgment, and utterly detest all idolatry, though the Mahometans believe them to be the most guilty of it. It is true, they perform their worship before fire, for which they have an extraordinary veneration, as believing it to be the most perfect emblem of the Deity. They have the same veneration for Zoroaster that the Jews have for Moses, esteeming him a prophet sent from God.

GAWSE, or GAWZE, in commerce, a very slight, thin, open kind of stuff, made of silk, and sometimes of thread; there are also figured gawzes, and some with gold or silver flowers on a silk ground.

GAZELLE, in zoology. See ANTELOPE, and CAPRA.

GAZONS, in fortification, pieces of fresh earth, covered with grass, and cut in form of a wedge, about a foot long and half a foot thick, to line the outsides of works made of earth, as ramparts, parapets, &c. See FORTIFICATION.

GEARS, or CHAINS, in country-affairs, the trappings and other harness belonging to draught horses or oxen.

GELATINE, in chemistry. If a piece of the fresh skin of an animal, after the hair and every impurity are carefully separated, is washed repeatedly in cold water till the liquid ceases to be coloured, or to subtract any thing; if the skin, thus purified, is put into a quantity of pure water, and boiled for some time, part of it will be dissolved. Let the decoction be slowly evaporated till it is reduced to a small quantity, and then put aside to cool. When cold, it will be found to have assumed a solid form, and to resemble precisely that tremulous substance well known to every body under the name of jelly. This is the substance called in chemistry gelatine. If the evaporation is still farther continued, by exposing the jelly to dry air, it becomes hard, semitransparent, breaks with a glassy fracture, and is, in short, the substance so much employed in different arts under the name of glue. Gelatine then is precisely the same with glue, only that it must be supposed always free from those impurities with which glue is so often contaminated.

Gelatine is semitransparent and colourless when pure. Its consistency and hardness vary considerably. The best kinds are very hard, brittle, and break with a glassy fracture. Its taste is insipid, and it has no smell. When thrown into water it swells very much, but does not readily dissolve; and when taken out, it is soft and gelatinous, but when allowed to dry, it recovers its former appearance. If it is put in this gelatinous state into warm water, it very soon dissolves, and forms a solution of an opal colour, and the more opaque according to the quantity of gelatine which it contains. Tremulous gelatine dissolves in a very small portion of hot water; but as the solution cools, it gelatinizes afresh. If this solution, as soon as it assumes the tremulous form, is mixed with cold water, and shaken, a complete solution takes place. Dry gelatine undergoes no change when kept, but in a gelatinous state, or when dissolved in water,

it very soon putrefies; an acid makes its appearance in the first place (probably the acetic), a fetid odour is exhaled, and afterwards ammonia is formed. When dry gelatine is exposed to heat, it whitens, curls up like horn, then blackens and gradually consumes to a coal; but tremulous gelatine first melts, assuming a black colour. When distilled, it yields, like most animal substances, a watery liquid impregnated with ammonia, and a fetid empyreumatic oil, leaving a bulky charcoal of difficult incineration. It is by no means a very combustible substance.

Acids dissolve gelatine with facility, even when diluted, especially when assisted by heat; but we are still ignorant of the changes produced upon it by these agents, except by nitric acid. When this acid is digested on it, a small quantity of azotic gas is disengaged, then abundance of nitrous gas; the gelatine is dissolved, except an oily matter which appears on the surface, and converted partly into oxalic and malic acids.

Muriatic acid dissolves glue with great ease. The solution is of a brown colour, and still continues strongly acid. It gradually lets fall a white powder. This solution precipitates tan in great abundance from water, and may be employed with advantage to detect tan when an alkali conceals it. Sulphuric acid acts much more slowly. The solution is brown and gradually deepens; sulphurous acid is exhaled during the action of sulphuric acid on glue. Neither sulphuric nor muriatic acid occasion any change in the solution of glue in water. Alkalies also dissolve gelatine with facility, especially when assisted by heat; but the solution does not possess the properties of soap.

None of the earths seem to combine with gelatine; at least they do not pricipitate it from its solution in water. The following table exhibits the effect of different earthly solutions when mixed with a pretty concentrated solution of common glue.

Substances.	Effects.
Lime water	No change.
Strontian water	No change.
Barytes water	Became milky. Precipit not dissolved by acetic acid.
Muriat of barytes	The same as the last.
Silicated potass	No change.
Aluminated potass	No change.
Oxalat of ammonia	Became milky.
Phosphat of soda	Became slightly milky.

The milkiness produced by some of these re-agents was not owing to their effect upon the gelatine, but upon the lime and the sulphuric acid which it contained.

The metals in their pure state have no effect upon gelatine; but several of the metallic oxides, when agitated in a solution of gelatine, have the property of depriving the water of the greatest part of that body, with which they form an insoluble compound. Several of the metallic salts likewise precipitate gelatine from water. The following table exhibits the result of mixing various metallic salts with a concentrated solution of gelatine, as far as experiments have gone.

Metallic Solutions.	Effects.
Nitromuriat of gold	A copious yellowish-white precipitate. Soluble by adding water.
Nitrat of silver	Becomes slightly milky.
Nitrat of mercury	A very copious curdy precipitate.
Oxymuriat of mercury	A copious white precip.
Sup. oxysulphat of mer.	No change.
Dry oxysulphat of mer.	Crystals become yellow, white flakes appear, and the liquid becomes transparent.
Prussiat of mercury	No change.
Oxynitrat of copper	No change.
Muriat of copper	Becomes milky.
Oxysulphat of copper	No change.
Cuprat of ammonia	No change.
Sulphat of iron	A few yellow flakes appear.
Oxysulphat of iron	Becomes slightly milky, as when alcohol is added.
Oxynitrat of iron	Assumes a pink colour.
Oxymuriat of iron	Becomes green.
Nitromuriat of tin	No change.
Oxymuriat of tin	Becomes slowly milky.
Nitrat of lead Acetat of lead Plumbat of potass Plumbat of lime	No change.
Muriat of zinc	No change.
Muriat of antimony	A copious flaky precip.
Tartar emetic	No change.
Nitrat of bismuth precipitable by water	Becomes milky.
Ditto, not precipitable by water	No change.
Muriat of arsenic	No change.

Gelatine is insoluble in alcohol. When alcohol is mixed with a solution of gelatine, the mixture becomes again transparent when agitated, unless the solution is concentrated, and the quantity of alcohol considerable. Gelatine is most probably equally insoluble in ether.

When the solution of tan is dropped into gelatine, a copious white precipitate appears, which soon forms an elastic adhesive mass, not unlike vegetable gluten. This precipitate is composed of gelatine and tan; it soon dries

in the open air, and forms a brittle resinous-like substance, insoluble in water, capable of resisting the greater number of chemical agents, and not susceptible of putrefaction. It resembles exactly overtanned leather. The precipitate is soluble in the solution of gelatine, as Mr. Davy first observed. Neither is the whole tan thrown down, unless the solutions both of tan and gelatine are somewhat concentrated. Tremulous gelatine, as was first observed by the same chemist, does not precipitate tan; but if we employ a solution of gelatine so strong that it galatinizes when cold, and heated till it becomes quite liquid, it answers best of all for throwing down tan. It is by this property of forming a white precipitate with tan that gelatine is usually detected in animal fluids. It is not, however, a perfectly decisive test, as there are two other animal substances, namely, albumen and mucilage, which are thrown down likewise by tan. Gelatine does not, properly speaking, combine with oils, but it renders them miscible with water, and forms a kind of emulsion

From the effects of different reagents on gelatine, and from the decomposition which it undergoes when heated, we see that it contains carbon, hydrogen, azote, and oxygen. But what the proportion of these constituents is, cannot be ascertained. The phosphat of lime, and the traces of soda, which it always yields, are most likely only held in solution by it.

Gelatine, like all other constituents of animal bodies, is susceptible of numerous shades of variations in its properties, and of course is divisible into an indefinite number of species. Several of these have been long known and manufactured for different purposes; and many curious varieties have been pointed out by Mr. Hatchett, in his admirable dissertations on shell, bone, and zoophytes, published in the Philosophical Transactions for 1797 and 1800. The most important species are the following:

1. *Glue.*—This well-known substance has been long manufactured in most countries, and employed to cement pieces of wood together. It is extracted by water from animal substances, and differs in its qualities according to the substances employed. Bones, muscles, tendons, ligaments, membranes, and skins, all yield it; but the quality is best when skins are employed; and those of old animals yield a much stronger glue than those of young animals. English glue is considered as the best, owing to the care with which it is made. The parings of hides, pelts from furriers, the hoofs and ears of horses, oxen, calves, sheep, &c. are the substances from which it is extracted in Britain; and quantities of these substances are imported for the purpose. They are first digested in lime-water to clean them, then steeped in clean water, laid in a heap till the water runs off, and then boiled in brass caldrons with pure water. The impurities are skimmed off as they rise; and when the whole is dissolved, a little alum or finely-powdered lime is thrown in. The skimming having been continued for some time, the whole is strained through baskets, and allowed to settle. The clear liquid is gently poured back into the kettle, boiled a second time, and skimmed till it is reduced to the proper consistency. It is then poured into large frames, where it concretes on cooling, into a jelly. It is cut by a spade into square cakes, which are again cut by means of a wire into thin slices; these slices are put into a kind of coarse net-work, and dried in the open air. The best glue is extremely hard and brittle; it has a dark-brown colour, and an equal degree of transparency without black spots. When put into cold water, it swells very much, and becomes gelatinous, but does not dissolve. When glue is soluble in cold water, it is a proof that it wants strength.

2. *Size.*—This substance differs from glue in being colourless, and more transparent. It is manufactured in the same way, but with more care; eel-skins, vellum, parchment, some kinds of white leather, and the skins of horses, cats, and rabbits, are the substances from which it is procured. It is commonly inferior to glue in strength. It is employed by paper-makers to give strength to that article, and likewise by linen-manufacturers, gilders, polishers, painters in fresco, &c.

3. *Isinglass.*—This substance agrees with size in being transparent, but it is much finer, and is therefore sometimes employed as an article of food. It is prepared in Russia from the air-bladders and sounds of different kinds of fish which occur in the mouths of large rivers; chiefly different species of accipenser, as the sturio, stellatus, huso, ruthenus, and likewise the siluris glaris. The bladder is taken from the fish, clean washed, the exterior membrane separated, cut lengthwise and formed into rolls, and then dried in the open air. When good, isinglass is of a white colour, semitransparent, and dry. It dissolves in water with more difficulty than glue, probably because it is not formed originally by solution. It differs from common glue in being soluble in alcohol. From the analysis of isinglass, by Mr. Hatchett, we learn that it is almost completely convertible into gelatine by solution and boiling. 500 grains of it left by incineration 1.5 grains of phosphat of soda mixed with a little phosphat of lime.

A coarse kind of isinglass is prepared from sea-wolves, porpoises, sharks, cuttle-fish, whales, and all fish without scales. The head, tail, and fins of these, are boiled in water and concentrated by evaporation, till it gelatinizes on cooling: it is then cast into flat slabs, and cut into tablets. This species is used for clarifying, stiffening silk, making sticking-plaster, and other purposes.

Gelatine exists in great abundance in animals, forming the constituent part of their solid and fluid parts. Its uses are numerous. In a state of jelly it constitutes one of the most nourishing and palatable species of food.

GELATINOUS, in pharmacy and medicine, any thing approaching to the glutinous consistence of a gelatine, or jelly.

GELD, or GILD, in law, a fine or compensation for an offence. Hence wergeld, in our ancient laws, was used for the value of a man slain; and orsgeld, of a beast.

GEM, in natural history, a common name for all precious stones, of which there are two classes, the pellucid and semipellucid. See GEMMA.

GEMINI, the Twins, in astronomy, one of the twelve signs of the zodiac, the third in order, beginning with Aries. This constellation, according to different authors, contains from 24 to 89 stars. It is represented by the figure of two twin-children, looking each other affectionately in the face, and supposed to be Castor and Pollux.

GEMMA, in natural history, a common name for all precious stones; of which there are two classes, the pellucid and semipellucid.

The bodies composing the class of pellucid gems are

bright, elegant, and beautiful fossils, naturally and essentially compound, ever found in small detached masses extremely hard, and of great lustre.

The bodies composing the class of semipellucid gems are stones naturally and essentially compound, not inflammable nor soluble in water, found in detached masses, and composed of crystalline matter debased by earth: however, they are but slightly debased, and are of great beauty and brightness, of a moderate degree of transparency, and are usually found in small masses.

The knowledge of gems depends principally on observing their hardness and colour. For hardness, they are commonly allowed to stand in the following order: the diamond the hardest of all; then the ruby, sapphire, hyacinth, emerald, amethyst, garnet, carneol, chalcedony, onyx, jasper, agate, porphyry, and marble. This difference, however, is not regular and constant, but frequently varies. Good crystals may be allowed to succeed the onyx; but the whole family of metallic glassy fluors seem to be still softer. In point of colour, the diamond is valued for its transparency, the ruby for its purple, the sapphire for its blue, the emerald for its green, the hyacinth for its orange, the amethyst carneol for its carnation, the onyx for its tawny, the jasper, agate, and porphyry, for their vermilion, green, and variegated colours, and the garnet for its transparent blood-red.

All these gems are sometimes found coloured and spotted, and sometimes quite limpid and colourless. In this case the diamond-cutter or polisher knows how to distinguish their different species by their different degree of hardness upon the mill. For the cutting or polishing of gems, the fine powder of the fragments of those that are next in degree of hardness is always required to grind away the softer; but as none of them are harder than the diamond, this can only be polished by its own powder.

Cronstedt observes of gems in general, that the colour of the ruby and emerald is said to remain in the fire, while that of the topaz flies off. Hence it is usual to burn the topaz, and then substitute it for the diamond.

With regard to the texture of gems, M. Magellan observes, that all of them are foliated or laminated, and of various degrees of hardness. Whenever the edges of these laminæ are sensible to the eye, they have a fibrous appearence, and reflect various shades of colour, which change successively according to their angular position to the eye. These are called by the French chatorantes; and what is a blemish in their transparency often enhances their value on acount of their scarcity. But when the substance of a gem is composed of a broken texture, consisting of various sets of laminæ differently inclined to each other, it emits at the same time various irradiations of different colours, which succeed one another according to their angle of position. This kind of gems has obtained the name of opals, and are valued in proportion to the brilliancy, beauty, and variety of their colours. Their crystallization, no doubt, depends on the same cause which produces that of salt, earths, and metals. The following table shows in general the component parts of gems according to the analysis of Bergman and M. Achard; the letter B prefixed to each denoting Bergman's analysis, and A that of Achard. We must observe, however, that under the description of the different gems our readers will find much more accurate statements.

		alum.	silex.	lime.	iron.

GEMMA, a bud. See Botany; and Plants, *physiology of.*

GEMONIÆ scalæ, in Roman antiquity, a place for executing criminals. It was situated on the Aventine mount, or tenth region of the city, and was, according to some, a place raised on several steps, whence they precipitated the criminals. But others will have it to have been a kind of dungeon, to which they descended by steps.

GEMS, *factitious*, or *counterfeit*. See Glass.

Gems, *imitation of antique.* There has been at different times a method practised by particular persons, of taking the impressions and figures of antique gems, with their engravings, in glass of the colour of the original gem. This has always been esteemed a very valuable method, and greatly preferable to the more ordinary ones of doing it on sealing-wax or brimstone: but, to the misfortune of the world, this art, being a secret only in the hands of some particular persons who got their bread by it, died with them, and every new artist was obliged to re-invent the method; till at length Mr. Homberg, having found it in great perfection, gave the whole process to the world to be no more forgotten or lost; and since that time it has been very commonly practised in France, and sometimes in other places.

Mr. Homberg was favoured in his attempts with all the engraved gems of the king's cabinet, and took such elegant impressions, and made such exact resemblances of the originals, and that in glasses so artfully tinged to the colour of the gems themselves, that the nicest judges were deceived in them, and often mistook them for the true antique stones. These counterfeit gems also serve, as well as the original ones, to make more copies from afterwards; so that there is no end of the numbers that may be made from one; and there is this farther advantage, that the copy may be easily made perfect, though the original should not be so, but should have sustained some damage from a blow or otherwise.

The great care in the operation is, to take the impression of the gem in a very fine earth, and to press down upon this a piece of proper glass, softened or half-melted at the fire, so that the figures of the impression made in the earth may be nicely and perfectly expressed upon the glass. In general the whole process much resembles that of the common founders. But when it is brought to the trial, there are found a number of difficulties which were

not to be foreseen, and which would not at all affect the common works of the founder. For his purpose every earth will serve that is fine enough to receive the impressions, and tough enough not to crack in the drying; these all serve for their use, because the metals which they cast are of a nature incapable of mixing with earth, or receiving it into them, even if both are melted together, so that the metal always easily and perfectly separates itself from the mould; but it is very difficult in these casts of glass. They are composed of a matter which differs in nothing from that of the mould, but that it has been run into this form by the force of fire, and the other has not yet been so run, and will mix itself inseparably with the glass in a large fire: consequently, if there is not great care used, as well in the choice of the glass as the manner of using it, when the whole is finished, there will be found great difficulty in separating the glass from the mould; and often this cannot be done without wholly destroying the impression.

All earths run more or less easily in the fire as they are more or less mixed with saline particles in their natural formation. As all salts make earths run into glass, and as it is necessary to use an earth on this occasion for the making a mould, it being also necessary, to the perfection of the experiment, that this earth should not melt or run, it is our business to search out for this purpose some earth which naturally contains very little salt. Of all the species of earth which Mr. Homberg examined on this occasion, none proved so much divested of salts, or so fit for the purpose, as the common tripela, or tripoli, used to polish glass and stones. Of this earth there are two common kinds; the one reddish, and composed of several flakes or strata; the other yellowish, and of a simple structure. These are both to be had in the shops. The latter kind is from the Levant; the former is found in England, France, and many other places. This tripela must be chosen soft and smooth to the touch, and not mixed with sandy or other extraneous matter. The yellowish kind is the best of the two, and is commonly called Venetian tripoli. This receives the impression very beautifully, and never mixes with the glass in the operation which the red kind sometimes does. Mr. Homberg usually employed both kinds at once in the following manner: 1st, powder a quantity of the red tripela in an iron mortar, and sifting it through a fine sieve, set it by for use; then scrape with a knife a quantity of the yellow tripela into a sort of powder, and afterwards rub it till very fine in a glass mortar with a glass pestle. The finer this powder is, the finer will be the impression, and the more accurately perfect the cast. The artificer might naturally suppose, that the best method to obtain a perfectly fine powder of this earth, would be by washing it in water; but he must be cautioned against this. There is naturally in this yellowish tripela a sort of unctuosity, which, when it is formed into a mould, keeps its granules together, and gives the whole an uniform glossy surface; now washing the powder takes away this unctuosity; and though it renders it much finer, it makes it leave a granulated surface, not this smooth one, in the mould; and this must render the surface of the cast less smooth.

When the two tripelas are thus separately powdered, the red kind must be mixed with so much water as will bring it to the consistence of paste, so that it may be moulded like a lump of dough between the fingers: this paste must be put into a small crucible of a flat shape, and about half an inch or little more in depth, and of such a breath at the surface as is a little more than that of the stone whose impression is to be taken. The crucible is to be nicely filled with this paste lightly pressed down into it, and the surface of the paste must be strewed over with the fine powder of the yellow tripela not wetted. When this is done, the stone of which the impression is to be taken must be laid upon the surface, and pressed evenly down into the paste with a finger and thumb, so as to make it give a strong and perfect impression; the tripela is then to be pressed nicely even to its sides with the fingers, or with an ivory knife. The stone must be thus left a few moments, for the humidity of the paste to moisten the dry powder of the yellow tripela which is strewed over it; then the stone is to be carefully raised by the point by a needle fixed in a handle of wood, and the crucible being then turned bottom upwards, the stone will fall out, and the impression will remain very beautifully on the tripela. If the sides of the cavity have been injured in the falling out of the stone, they may be repaired, and the crucible must then be set, for the paste to dry, in a place where it will not be incommended by the dust.

The red tripela, being the more common and the cheaper kind, is here made to fill the crucible only to save the other, which alone is the substance fit for taking the impression. When the stone is taken out, it must be examined, to see whether any thing is lodged in any part of the engraving, because, if there is any of the tripela remaining, there will of course be so much wanting in the impression. When the crucible and paste are dry, a piece of glass must be chosen of a proper colour, and cut to a size proper for the figure; this must be laid over the mould, but in such a manner that it shall not touch the figures, otherwise it would spoil them. The crucible is then to be brought near the furnace by degrees, and gradually heated till it cannot be touched without burning the fingers; then it is to be placed in the furnace under a muffle surrounded with charcoal. Several of these small crucibles may be placed under one muffle; and when they are properly disposed, the aperture of the muffle should have a large piece of burning charcoal put to it, and then the operator is to watch the process, and see when the glass begins to look bright: this is the signal of its being fit to receive the impression. The crucible is then to be taken out of the fire, and the hot glass must be pressed down upon the mould with an iron instrument, to make it receive the regular impression; as soon as this is done, the crucible is to be set by the side of the furnace out of the way of the wind, that it may cool gradually without breaking. When it is cold, the glass is to be taken out, and its edges should be grated round with pincers, in order to prevent its flying afterwards, which is an accident that sometimes happens when this caution has been omitted, especially when the glass is naturally tender. The different coloured glasses are of different degrees of hardness, according to their composition; but the hardest to melt are always the best for this purpose, and this is known by a few trials.

If it is desired to copy a stone in relief which is natu-

rally in creux, or to take one in creux which is naturally in relief, there needs no more than to take an impression, first in wax or sulphur, and to mould that upon the paste of tripela instead of the stone itself; then proceeding in the manner before directed, the process will have the desired effect.

A still more simple and easy method is by taking the casts in gypsum, or plaister of Paris, as it is commonly called. For this purpose the gypsum must be finely pulverized, and then mixed with clear water to the consistence of thick cream. This is poured upon the face of the gem or seal of which the impression is wanted, and which must be previously moistened with oil to facilitate the separation of the cast; and in order to confine the liquid plaister it is only necessary to pin a slip of oiled paper round the sides of the seal by way of a cap or rim. When the plaister is dry, it is to be taken off, and set before the mouth of the furnace, in order to free it entirely from moisture, when it is fit to be used as a matrix in the same way as that formed with the tripoli earths. Only no crucible or other receptacle is at all necessary, the casts being formed like so many small cakes half an inch thick, and then put into the furnace with the bits of glass upon them. The glass, after coming to a proper heat, is pressed down upon the mould with an iron spatula to receive the desired impression, the pressure required being more or less, according to the size of the stone. This method has been long practised very successfully, and with no small emolument, by that ingenious seal-engraver, Mr. Denchar of Edinburgh. The only respect in which it is inferior to the other more operose and expensive methods, consists in the chance of air-bubbles arising in pouring on the plaister; which chance, however, is less in proportion to the fineness of the gypsum employed. When air-bubbles do occur, the casts may be laid aside, as it is so easy to replace them.

Of all the artists and ingenious men who have taken impressions of engraved gems in sulphur and in paste, no one seems to have carried that art to such perfection as Mr. James Tassie, a native of Glasgow, but who latterly resided in London.

Mr. Tassie, profiting by the former publications of this sort, and by expense, industry, and access to many cabinets in England and other kingdoms to which former artists had not obtained admission, increased his collection of impressions of ancient and modern gems to the number of above 15,000 articles. It is the greatest collection of this kind that ever existed, and serves for all the purposes of artists, antiquaries, scholars, men of taste, and even philosophers. The great demand for his pastes was perhaps owing in the beginning to the London jewellers, who introduced them into fashion by setting them in rings, seals, bracelets, necklaces, and other trinkets.

The reputation of this collection having reached the empress of Russia, she was pleased to order a complete set; which, being accordingly executed in the best and most durable manner, were arranged in elegant cabinets, and are now placed in the noble apartments of her imperial majesty's superb palace at Czarsko Zelo.

Mr. Tassie, in executing this commission, availed himself of all the advantages which the improved state of chemistry, the various ornamental arts, and the knowledge of the age, seemed to afford. The impressions were taken in a beautiful white enamel composition, which is not subject to shrink or form air-bladders, which emits fire when struck with steel, and takes a fine polish, and which shows every stroke and touch of the artist in higher perfection than any other substance. When the colours, mixed colours, and nature of the respective originals, could be ascertained, they were imitated as completely as art can imitate them; insomuch that many of the paste intaglios and cameoes in this collection are such faithful imitations, that artists themselves have owned they could hardly be distinguished from the originals. And when the colour and nature of the gems could not be authenticated, the pastes were executed in agreeable, and chiefly transparent, colours; constant attention being bestowed to preserve the outlines, extremities, attributes, and inscriptions.

GENDARMERIE, *Fr.* The gendarmerie was a select body of cavalry that took precedence of every regiment of horse in the French service, and ranked immediately after the king's household. The reputation of the gendarmerie was so great, and its services so well estimated by the king of France, that when the emperor Charles V. in 1552, sent a formal embassy to the court of Versailles to request a loan of money, and the assistance of the gendarmerie to enable him to repulse the Turks; Francis I. returned the following answer: "With respect to the first object of your mission, (addressing himself to the ambassador) I am not a banker; and with regard to the other, as my gendarmerie is the arm which supports my sceptre, I never expose it to danger, without myself sharing its fatigue and glory."

The uniform of the gendarmerie, as well as of the light cavalry, under the old French government, was scarlet, with facings of the same colour. The coat was formerly more or less laced with silver, according to the king's pleasure. A short period before the revolution, it was only laced on the cuff. The waistcoat was of buff leather, and the bandouleer of the same, silver-laced; the hat was edged with broad silver lace. The horse-cloths and holster-caps were red, and the arms of the captain embroidered on the corners of the saddle-cloths, and on the front of the holsters.

In 1762, a considerable body of men was raised by order of Louis XV. The soldiers who composed it were called gensdarmes. And in 1792 the number was considerably augmented, consisting of horse and foot, and being discriminately called gensdarmes; but their clothing was altered to deep blue. Their pay was greater than what the rest of the army enjoyed; and when others were paid in paper currency, they received their subsistence in hard cash (en argent sonant). They possessed these privileges on account of the proofs they were obliged to bring of superior claims to military honour, before they could be enlisted as gensdarmes. It was necessary, in fact, that every individual amongst them should produce a certificate of six or eight years service.

GENDARMES (gens d'armes) de la garde, a select body of men so called during the old government of France, and still preserved in that country; but their services are applied to different purposes. They consisted originally of a single company which was formed by Henry IV. when he ascended the throne. He distinguished them from his other troops by styling them

hommes d'armes de ses ordonnances, men at arms under his own immediate orders. They consisted of men best qualified for every species of military duty, and were to constitute a royal squadron, at whose head the king himself personally engaged the enemy, as necessity might require. He gave this squadron to his son, the dauphin, who was afterwards king of France, under the name and title of Louis XIII.

GENDER, among grammarians, a division of nouns, or names, to distinguish the two sexes.

GENEALOGICA ARBOR, or tree of consanguinity, signifies a genealogy or lineage drawn out under the figure of a tree, with its root, stock, branches, &c. The genealogical degrees are usually represented in circles, ranged over, under, and aside each other. This the Greeks called stemmata, a word signifying crown, or garland.

GENEALOGY, an enumeration of a series of ancestors, or a summary account of the relations and alliances of a person or family, both in the direct and collateral line.

GENEPPA. See GARDENEA.

GENERAL, in a military sense, is an officer in chief, to whom the prince or senate of a country have judged proper to intrust the command of their troops. He holds this important trust under various titles: as captain-general, in England and Spain; feldt mareschal in Germany, or mareschal in France.

In the British service the king is constitutionally, and in his own proper right, captain-general. He has ten aid-de-camps; every one of whom enjoys the brevet-rank of full colonel in the army. Next to his majesty is the commander in chief, whom he sometimes honours with the title of captain-general. During the expedition to Holland, his royal highness the duke of York was entrusted with this important charge.

The natural qualities of a general are a martial genius, a solid judgment, a healthy robust constitution, intrepidity and presence of mind on critical occasions, indefatigability in business, goodness of heart, liberality, a reasonable age; if too young, he may want experience and prudence; if too old, he may not have vivacity enough. His conduct must be uniform, his temper affable, but inflexible in maintaining the police and discipline of an army.

The acquired qualities of a general should be secrecy, justice, sobriety, temperance, knowledge of the art of war from theory and practice, the art of commanding and speaking with precision and exactness, great attention to preserve the lives and supply the wants of the soldiers; and a constant study of the characters of the officers of his army, that he may employ them according to their talents. His conduct appears in establishing his magazines in the most convenient places; in examining the country, that he may not engage his troops too far, while he is ignorant of the means of bringing them off; in subsisting them, and in knowing how to take the most advantageous posts, either for fighting, retreating, or shunning a battle. His experience inspires his army with confidence, and an assurance of victory; and his quality, by creating respect, augments his authority. By his liberality he gets intelligence of the strength and designs of the enemy, and by this means is enabled to take the most successful measures. He ought to be fond of glory, to have an aversion to flattery, to render himself beloved, and to keep a strict discipline and regular subordination.

The office of a general is to regulate the march and encampment of the army; in the day of battle to chuse out the most advantageous ground; to make the disposition of the army; to post the artillery, and where there is occasion, to send his orders by his aid-de-camps. At a siege he is to cause the place to be invested, to regulate the approaches and attacks, to visit the works, and to send out detachments to secure the convoy and foraging parties.

GENERAL TERMS, among logicians, those which are made signs of general ideas.

GENERAL *of horse*, and GENERAL *of foot*, are posts next under the general of the army, and these have upon all occasions an absolute authority over all the horse and foot in the army.

GENERAL *of the artillery*, or *Master* GENERAL *of the ordnance*. See ORDNANCE.

GENERAL is also used for a particular march; or beat of drum, being the first which gives notice, commonly in the morning early, for the infantry to be in readiness to march.

GENERAL is also used for the chief of an order of monks; or of all the houses and congregations, established under the same rule. Thus we say, the general of the Franciscans, Cistercians, &c.

GENERALISSIMO, a supreme and absolute commander in the field. This word is generally used in most foreign languages. It was first invented by the absolute authority of carnidal Richelieu, when he went to command the French army in Italy.

GENERATING LINE OF FIGURE, in geometry, is that which by its motion produces any other plane or solid figure. Thus a right line moved any way parallel to itself, generates a parallelogram; round a point in the same plane, with one end fastened in that point, it generates a circle. One entire revolution of a circle, in the same plane, generates the cycloid; and the revolution of a semicircle round its diameter, generates a sphere.

GENERATION. See COMPARATIVE ANATOMY, and PHYSIOLOGY.

GENESIS, among mathematicians, signifies the formation or production of some figure or quantity.

GENEVA, or GIN, among distillers, an ordinary malt-spirit distilled a second time, with the addition of some juniper-berries. See DISTILLATION.

GENIOSTOMA, a genus of the monogynia order, in the pentandria class of plants. The calyx is a turbinated quinquefid perianthium; the corolla monopetalous and tubular; the stamina five short filaments; the antheræ oblong; the seeds very numerous and subangulated, placed on a filiform receptacle. There is one species, a native of the South Seas.

GENISTA, BROOM, or DYER'S-WEED, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The calyx is bilabiate; the upper lip bidented, the under one tridentate; the vexillum is oblong and reflexed, or turned back from the pistil and stamina. There are 17 species, of which the most remarkable are the cytiso-genista, or common broom, and the tinctoria,

or dyer's-weed. The first is too well known to need description. Its young flowers are sometimes preserved as pickles; and the plant, when burnt, affords a tolerably pure alkaline salt. Dr. Mead relates the case of a dropsical patient that was cured by taking half a pint of a decoction of green broom-tops, with a spoonful of whole white mustard-seed, every morning and evening. The patient had been tapped three times, and tried the usual remedies before. The seeds, or an infusion of them drunk freely, have been known to produce similar happy effects; but these are to be expected in very few instances. Cows, horses, and sheep, refuse the plant. 2 The tinctoria is also a native of Britain. It rises with shrubby stalks three feet high, with spear-shaped leaves placed alternate, and terminated by several spikes of yellow flowers, succeeded by pods. The branches of the plant are used by dyers for giving a yellow colour; whence it is called dyer's-broom, green-wood, wood waxen, or dyer's-weed. A dram and half of the powdered seeds operates as a mild purgative. A decoction of the plant is diuretic, and, like the former, has proved serviceable in dropsical cases. Horses, cows, goats, and sheep, eat it.

GENITIVE, in grammar, the second case of the declension of nouns.

GENTIANA. Gentian, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 20th order, rotaceæ. The corolla is monopetalous, the capsule bivalved and unilocular; there are two longitudinal receptacles. There are 53 species. The most remarkable are the following:

1. The lutea, or common gentian of the shops. This is a native of the mountainous parts of Germany, whence the roots, the only part used in medicine, are brought to this country. They have a yellowish-brown colour, and a very bitter taste. The lower leaves are of an oblong oval shape, a little pointed at the end, stiff, of a yellowish green, and have five large veins on the back of each. The stalk rises four or five feet high, with leaves growing by pairs at each joint, almost embracing the stalk at their base. They are of the same form with the lower, but diminish gradually in their size to the top. The flowers come out in whorls at the joints on the upper part of the stalks, standing on short footstalks, whose origin is in the wings of the leaves. They are of a pale-yellow colour. The roots of this plant are very frequently used in medicine as stomachic bitters. In taste they are less exceptionable than most of the substances of this class. Infusions of gentian-root flavoured with orange-peel are sufficiently grateful. Some years ago a poisonous root was discovered among the gentian brought to London, the use of which occasioned violent disorders, and in some cases death. This root is easily distinguished from the gentian, by its being internally of a white colour, and void of bitterness.

2. The centaureum, or lesser centaury of the shops, is a native of many parts of Britain. It grows on dry pastures, and its height is commonly proportioned to the goodness of the soil, as in rich soils it will grow to the height of a foot, but in poor ones not above three or four inches. It is an annual plant, with upright branching stalks, and small leaves, placed by pairs. The flowers grow in form of an umbel at the top of the stalk, and are of a bright purple colour. They come out in July, and the seed ripens in autumn. The plant cannot be cultivated in gardens. The tops are an useful aperient bitter, in which view they have been often used in the practice of medicine.

3. The acaulis, a beautiful little plant for the flower garden, conspicuous for its fine changeable azure blue flowers. It is a native of the Alps.

GENTILE, *gentilis*, in the Roman law and history, a name which sometimes expresses what the Romans otherwise called barbarians, whether they were allies of Rome or not: but this word was used in a more particular sense for all strangers and foreigners not subject to the Roman empire, in contradistinction to provincials, or an inhabitant of a province of the empire.

GENTLEMAN, according to sir Edward Coke, is one who bears coat-armour, the grant of which adds gentility to a man's family. 2 Inst. 667.

GENUS, among metaphysicians and logicians, denotes a number of beings, which agree in certain general properties, common to them all, so that a genus is nothing but an abstract idea, expressed by some general name or term.

Genus, in natural history, a subdivision of any class or order of natural beings, whether of the animal, vegetable, or mineral kingdoms; all agreeing in certain common characters.

Genus, in music, by the ancients called genus melodiæ, is a certain manner of dividing and subdividing the principles of melody, that is, the consonant and dissonant intervals, into their concinnous parts.

GEOCENTRIC, in astronomy, is applied to a planet or its orbit to denote it concentric with the earth, or as having the earth for its centre, or the same centre with the earth.

Geocentric *latitude of a planet,* is its distance from the ecliptic as it is seen from the earth, which even though the planet be in the same point of her orbit, is not constantly the same, but alters according to the position of the earth in respect to the planet.

Geocentric *place of a planet,* the place in which it appears to us from the earth, supposing the eye there fixed: or it is a point in the ecliptic to which a planet seen from the earth is referred.

GEOFFROYA, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaciæ. The calyx is quinquefid, the fruit an oval plum, the kernel compressed. There are two species; the intermis, or cabbage bark tree, is a native of Brasil and Jamaica. The wood of this tree is used in building; but it is chiefly valued for its bark, which is administered as an anthelmintic medicine. From this medical property it is also called the worm-bark tree. This bark is of a grey colour externally, but black and furrowed on the inside. It has a mucilaginous and sweetish taste, and a disagreeable smell. It is given in cases of worms, in form of powder, decoction, syrup, and extract. The decoction is preferred, and is made by slowly boiling an ounce of the fresh-dried bark in a quart of water, till it assumes the colour of Madeira wine. This, sweetened, is the syrup; evaporated, it forms an extract. It commonly produces some sickness and purging; sometimes violent effects, as

vomiting, delirium, and fever. These last are said to be owing to an over-dose, or to drinking cold water, and are relieved by the use of warm water, castor oil, or a vegetable acid. It should always be begun in small doses. But when properly and cautiously administered, it is said to operate as a very powerful anthelmintic, particularly for the explosion of the lumbrici, which are a very common cause of disease in the West Indies.

GEOGRAPHY, is a word derived from the Greek language, and implies a description of the earth. It is sometimes contrasted with hydrography, which signifies a description of the water, that is, of seas, lakes, rivers, &c. including marine charts. Anciently both were considered in connection with astronomy, as parts of cosmography; which attempted to delineate the universe. Geography is more justly contrasted with chorography, which illustrates a country or province; and still more with topography, which describes a particular place, or smaller district.

What is called general geography embraces a wide view of the subject; regarding the earth astronomically as a planet, the grand divisions of land and water, the winds, tides, meteorology, and may extend to what is called mechanical geography, including directions for the construction of globes, maps, and charts.

Among other divisions of this science may be named sacred geography, solely employed in the illustration of the scriptures; ecclesiastical geography, which describes the government of the church as divided into patriarchates, archbishopricks, bishopricks, archdeanries, &c. with their respective boundaries, which frequently vary much from those of the secular provinces; and physical geography, or geology which investigates the interior of the earth, so far only as real discoveries can be made. See GEOLOGY.

Geography, popularly considered, is occupied in the description of the various regions of this globe, chiefly as being divided among various nations, and improved by human art and industry.

GEOGRAPHY, *history of*. The study of geography being of so much practical importance in life, must have commenced in the early ages of the world. It was regarded as a science by the Babylonians and Egyptians, from whom it passed to the Greeks, and from these to the Romans, the Arabians, and the western nations of Europe. Thales of Miletus, in the 6th century before Christ, first made observations on the apparent progress of the sun from tropic to tropic; and is said to have written two treatises, the one on the tropic, and the other on the equinox, whence he was led to the discovery of the four seasons, which are determined by the equinoxes and solstices. We are assured this knowledge was obtained by means of the gnomon. Thales, it is also said, constructed a globe, and represented the land and sea upon a table of brass.

Meton and Euctemon observed the summer solstice at Athens, on the 27th of June, 432 years before Christ, by watching narrowly the shadow of the gnomon, with the design of fixing the beginning of their cycle of 19 years.

Timocharis and Aristillus, who began their observations about 295 B. C., first attempted to fix the latitudes and longitudes of the fixed stars, by considering their distances from the equator, &c. One of their observations gave rise to the discovery of the precession of the equinoxes, which was first remarked by Hipparchus about 150 years after; who also made use of their method for delineating the parallels of latitude and the meridians, on the surface of the earth; thus laying the foundation of this science as it now appears. See EQUINOXES, *precession of*.

The latitudes and longitudes, thus introduced by Hipparchus, were not however much attended to till Ptolemy's time. Strabo, Vitruvius, and Pliny, have all of them entered into a minute geographical description of the situation of places, according to the length of the shadows of the gnomon, without noticing the longitudes and latitudes.

Maps at first were little more than rude outlines, and topographical sketches of different countries. The earliest on record were those of Sesostris, mentioned by Eustathius, who says, that "this Egyptian king, having traversed great part of the earth, recorded his march in maps, and gave copies of them not only to the Egyptians, but to the Scythians, to their great astonishment." Some have imagined, with much probability, that the Jews made a map of the Holy Land when they gave the different portions to the nine tribes at Shiloh; for Joshua tells us that they were sent to walk through the land, and that they described it in seven parts in a book; and Josephus relates that when Joshua sent out people from the different tribes to measure the land, he gave them as companions persons well skilled in geometry, who could not be mistaken in the truth.

The first Grecian map on record was that of Anaximander, mentioned by Strabo, supposed to be that referred to by Hipparchus under the designation of the ancient map. Herodotus minutely describes a map made by Aristagoras, tyrant of Miletus, which will serve to give some idea of the maps of those times. He relates, that Aristagoras showed it to Cleomenes, king of Sparta, to induce him to attack the king of Persia at Susa, in order to restore the Ionians to their ancient liberty. It was traced upon brass or copper, and seems to have been a mere itinerary, containing the route through the intermediate countries which were to be traversed in that march, with the rivers Halys, the Euphrates, and Tigris, which Herodotus mentions as necessary to be crossed in that expedition. It contained one straight line called the royal road, or highway, which took in all the stations or places of encampment from Sardis to Susa; being 111 in the whole journey, and containing 13,500 stadia, or 1687½ Roman miles of 5000 feet each.

Eratosthenes first attempted to reduce geography to a regular system, and introduced a regular parallel of latitude, which began at the straits of Gibraltar, passed eastwards through the isle of Rhodes, and so on to the mountains of India, noting all the intermediate places through which it passed. In drawing this line, he was not regulated by the same latitude, but by observing where the longest day was 14 hours and a half, which Hipparchus afterwards determined was the latitude of 36 degrees.

This first parallel through Rhodes was ever after considered with a degree of preference, in constructing all the ancient maps; and the longitude of the then known

world was often attempted to be measured in stadia and miles, according to the extent of that line, by many succeeding geographers.

Eratosthenes soon after attempted not only to draw other parallels of latitude, but also to trace a meridian at right angles to these, passing through Rhodes and Alexandria down to Syene and Meroe; and at length he undertook the arduous task of determining the circumference of the globe, by an actual measurement of a segment of one of its great circles. To find the magnitude of the earth is indeed a problem which has engaged the attention of astronomers and geographers ever since the spherical figure of it was known. It seems Anaximander was the first among the Greeks who wrote upon this subject. Archytas of Tarentum, a Pythagorean, famous for his skill in mathematics and mechanics, also made some attempts in this way; and Dr. Long conjectures that these are the authors of the most ancient opinion that the circumference of the earth is 400,000 stadia; and Archimedes makes mention of the ancients who estimated the circumference of the earth at only 30,000 stadia.

As to the methods of measuring the circumference of the earth, it would seem, from what Aristotle says in his treatise De Cœlo, that they were much the same as those used by the moderns, deficient only in the accuracy of the instruments. That philosopher there says, that different stars pass through our zenith, according as our situation is more or less northerly; and that in the southern parts of the earth stars come above our horizon, which are no longer visible if we go northward. Hence it appears that there are two ways of measuring the circumference of the earth; one by observing stars which pass through the zenith of one place, and do not pass through that of another; the other, by observing some stars which come above the horizon of one place, and are observed at the same time to be in the horizon of another. The former of these methods, which is the best, was followed by Eratosthenes at Alexandria in Egypt, 250 years before Christ. He knew that at the summer solstice, the sun was vertical to the inhabitants of Syene, a town on the confines of Ethiopia, under the tropic of Cancer, where they had a well made to observe it, at the bottom of which the rays of the sun fell perpendicularly the day of the summer solstice: he observed by the shadow of a wire set perpendicularly in an hemispherical bason, how far the sun was on that day at noon distant from the zenith of Alexandria; when he found that distance was equal to the 50th part of a great circle in the heavens. Then supposing Syene and Alexandria under the same meridian, he inferred that the distance between them was the 50th part of a great circle upon the earth; and this distance being by measure 5000 stadia, he concluded that the whole circumference of the earth was 250,000 stadia. But as this number divided by 360 would give $694\frac{4}{9}$ stadia to a degree, either Eratosthenes himself, or some of his followers, assigned the round number 700 stadia to a degree, which multiplied by 360, makes the circumference of the earth 252,000 stadia; whence both these measures are given by different authors as that of Eratosthenes.

In the time of Pompey the Great, Posidonius determined the measure of the circumference of the earth by the 2d method above hinted by Aristotle, viz. the horizontal observations. Knowing that the star called Canopus was but just visible in the horizon of Rhodes, and at Alexandria finding its meridian height was the 48th part of a great circle in the heavens, or $7\frac{1}{2}$ deg. answering to the like quantity of a circle on the earth; then supposing these two places under the same meridian, and the distance between them 5000 stadia, the circumference of the earth will be 240,000 stadia; which is the first measure of Posidonius. But according to Strabo, Posidonius made the measure of the earth to be 180,000 stadia, at the rate of 500 stadia to a degree. The reason of this difference is thought to be, that Eratosthenes measured the distance between Rhodes and Alexandria, and found it only 3750 stadia; taking this for a 48th part of the earth's circumference, which is the measure of Posidonius, the whole circumference will be 180,000 stadia. This measure was received by Marinus of Tyre, and is usually ascribed to Ptolemy. But this measurement is subject to great uncertainty, both on account of the great refraction of the stars near the horizon, the difficulty of measuring the distance at sea between Rhodes and Alexandria, and by supposing those places under the same meridian, when they are really very different.

Several geographers afterwards made use of the different heights of the pole in distant places under the same meridian, to find the dimensions of the earth. About the year 800 the khalif Almemun had the distance measured between two places that were two degrees asunder, and under the same meridian, in the plains of Sinjar in the Red Sea; and the result was, that the degree at one time was found equal to 56 miles, and at another $56\frac{1}{3}$ or $56\frac{2}{3}$ miles.

The next attempt to find out the circumference of the earth was in 1525, by Fernelius, a learned philosopher of France. For this purpose he took the height of the pole at Paris, going thence directly northwards, till he came to the place where the height of the pole was one degree more than at that city. The length of the way was measured by the number of revolutions made by one of the wheels of his carriage; and after proper allowances for the declivities and turnings of the road, he concluded that 68 Italian miles were equal to a degree of the earth.

According to these methods many other measurements of the earth's circumference have since that time been made, with much greater accuracy: a particular account of which is give under the article DEGREE.

Though the maps of Eratosthenes were the best of his time, they were yet very imperfect and inaccurate. They contained little more than the states of Greece, and the dominions of the successors of Alexander, digested according to the surveys above-mentioned. He had indeed seen, and has quoted, the voyages of Pythias into the great Atlantic ocean, which gave him some faint ideas of the western part of Europe; but so imperfect, that they could not be realized into the outlines of a chart. Strabo says he was very ignorant of Gaul, Spain, Germany, and Britain; and he was equally ignorant of Italy, the coast of the Adriatic, Pontus, and all the countries towards the north.

Such was the state of geography, and the nature of the maps, before the time of Hipparchus. He made a closer

connection between geography and astronomy, by determining the latitudes from celestial observations.

War has usually been the occasion of making or improving the maps of countries; and accordingly geography made great advances from the progress of the Roman arms. In all the provinces occupied by that people, camps were every where constructed at proper intervals, and good roads made for communication between them; and thus civilization and surveying were carried on according to system through the whole extent of that empire. Every new war produced a new survey and itinerary of the countries where the scenes of action passed; so that the materials of geography were accumulated by every additional conquest. Polybius says, that at the beginning of the second Punic war, when Hannibal was preparing his expedition against Rome, the countries through which he was to pass were carefully measured by the Romans. And Julius Cæsar caused a general survey of the Roman empire to be made, by a decree of the senate. Three surveyors had this task assigned them, which they completed in 25 years. The Roman itineraries that are still extant, also shew what care and pains they had been at in making surveys in all the different provinces of their empire, and Pliny has filled the 3d, 4th, and 5th books of his Natural History with the geographical distances that were thus measured. Other maps are also still preserved, known by the name of the Pentigerian Tables, published by Welser and Bertius, which give a good specimen of what Vegetius calls the itinera picta, for the better direction of their armies in their march.

The Roman empire had been enlarged to its greatest extent, and all its provinces well known and surveyed, when Ptolemy, about 150 years after Christ, composed his system of geography. The chief materials he employed in composing this work, were the proportions of the gnomon to its shadow, taken by different astronomers at the times of the equinoxes and solstices; calculations founded on the length of the longest days; the measured or computed distances of the principal roads contained in their surveys and itineraries; and the various reports of travellers and navigators. All these were compared together, and digested into one uniform body or system; and afterwards were translated by him into a new mathematical language, expressing the different degrees of latitude and longitude, after the invention of Hipparchus, which had been neglected for 250 years.

Ptolemy's system of geography, notwithstanding it was still very imperfect, continued in vogue till the last three or four centuries, within which time the great improvements in astronomy, the many discoveries of new countries by voyagers, and the progress of war and arms, have contributed to bring it to a very considerable degree of perfection.

Principals of geography.

The fundamental principles of geography are, the spherical figure of the earth, its rotation on its axis, its revolution round the sun, and the position of the axis or line round which it revolves with regard to the celestial luminaries. That the earth and sea taken together constitute one vast sphere is demonstrable by the following arguments: 1. To people at sea the land disappears, though near enough to be visible was it not for the intervening convexity of the water. 2. The higher the eye is placed, the more extensive is the prospect; whence it is common for sailors to climb up to the tops of the masts to discover land or ships at a distance. But this would give them no advantage, was it not for the convexity of the earth; for upon an infinitely extended plane objects would be visible at the same distance whether the eye was high or low, nor would any of them vanish till the angle under which they appeared became too small to be perceived. 3. To people on shore, the mast of a ship at sea appears before the hull; but was the earth an infinite plane, not the highest object, but the largest, would be longest visible; and the mast of a ship would disappear, by the smallness of its angle, long before the hull did so. 4. The convexity of any piece of still water of a mile or two in extent may be perceived by the eye. A little boat, for instance, may be perceived by a man who is any height above the water; but if he stoops down or lays his eye near the surface, he will find that the fluid appears to rise and intercept the view of the boat entirely. 5. The earth has been often sailed round, as by Magellan, Drake, Dampier, Anson, Cook, and many other navigators, which demonstrates that the surface of the ocean is spherical; and that the land is very little different may easily be proved from the small elevation of any part of it above the surface of the water. The mouths of rivers which run 1000 miles are not more than one mile below their sources, and the highest mountains are not quite four miles of perpendicular height; so that, though some parts of the land are elevated into hills, and others depressed into valleys, the whole may still be accounted spherical. 6. An undeniable, and indeed ocular, demonstration of the spherical figure of the earth is taken from the round figure of its shadow which falls upon the moon in time of eclipses. As various sides of the earth are turned towards the sun during the time of different phenomena of this kind, and the shadow in all cases appears circular, it is impossible to suppose the figure of the earth to be any other than spherical. The inequalities of its surface have no effect upon the earth's shadow on the moon; for as the diameter of the terraqueous globe is very little less than 8000 miles, and the height of the highest mountains on earth not quite four, we cannot account the latter any more than the 2000th part of the former, so that the mountains bear no more proportion to the bulk of the earth, than grains of dust bear to that of a common globe.

A great many of the terrestrial phenomena depend upon the globular figure of the earth, and the position of its axis with regard to the sun, particularly the rising and setting of the celestial luminaries, the length of the days and nights, &c.

Though the sun rises and sets all over the world, the circumstances of his doing so are very different in different countries. The most remarkable of these circumstances is the duration of the light, not only of the sun himself, but of the twilight before he rises and after he sets. In the equatorial regions, for instance, darkness comes on very soon after sunset; because the convexity of the earth comes quickly in between the eye of the observer and the luminary, the motion of the earth being much more rapid there than any where else. In our climate the twilight always continues two hours, or thereabouts, and during the summer season it con-

tinues in a considerable degree during the whole night. In countries farther to the northward or southward, the twilight becomes brighter and brighter as we approach the poles, until at last the sun does not appear to touch the horizon, but goes in a circle at some distance above it for many days successively. In like manner, during the winter, the same luminary sinks lower and lower, until at last he does not appear at all; and there is only a dim twinkling of twilight for an hour or two in the middle of the day. By reason of the refraction of the atmosphere, however, the time of darkness, even in the most inhospitable climates, is always less than that of light; and so remarkable is the effect of this property, that in the year 1682, when some Dutch navigators wintered in Nova Zembla, the sun was visible to them 16 days before he could have been seen above the horizon, had there been no atmosphere. The reason of all this is, that in the northern and southern regions only a small part of the convexity of the globe is interposed betwixt us and the sun for many days, and in the high latitudes none at all. In the warmer climates the sun has often a beautiful appearance at rising and setting, from the refraction of his light through the vapours which are copiously raised in those parts. In the colder regions, halos, parhelia, aurora borealis, and other meteors, are frequent; the two former owing to the great quantity of vapour continually flying from the warm regions of the equator to the colder ones of the poles. In the high northern latitudes, thunder and lightnings are unknown, or but seldom heard of; but the more terrible phenomena of earthquakes, volcanoes, &c. are by no means unfrequent. These, however, seem only to affect islands and the maritime parts of the continent.

Notwithstanding the seeming inequality in the distribution of light and darkness, however, it is certain, that throughout the whole world there is nearly an equal proportion of light diffused on every part, abstracting from what is absorded by clouds, vapours, and the atmosphere itself. The equatorial regions have indeed the most intense light during the day, but the nights are long and dark; while, on the other hand, in the northerly and southerly parts, though the sun shines less powerfully, yet the length of time that he appears above the horizon, with the greater duration of the twilight, compensates for the seeming deficiency.

Was the earth a perfect plane, the sun would appear to be vertical in every part of it; for, in comparison with the immense magnitude of that luminary, the diameter of this globe itself is but very small; and as the sun, was he near to us, would do much more than cover the whole earth, so, though he was removed to any distance, the whole diameter of the latter would make no difference in the apparent angle of altitude. By means of the globular figure of the earth also, along with the great disparity between the diameters of the two bodies, some advantage is given to the day over the night; for thus the sun, being immensely the larger of the two, shines upon more than one-half of the earth; whence the unenlightened part has a shorter way to go before it again receives the benefit of his rays. This difference is greater in the inferior planets Venus and Mercury than in the earth.

To the globular figure of the earth likewise is owing the long moonlight which the inhabitants of the polar regions enjoy. The same thing likewise occasions the appearance and disappearance of certain stars at some seasons of the year in some countries; for, was the earth flat, they would all be visible in every part of the world at the same time. Hence most probably has arisen the opinion of the influence of certain stars upon the weather and other sublunary matters. In short, on the globular figure of the earth depends the whole present appearance of nature around us; and was the shape of the planet we inhabit to be altered to any other, besides the real differences which would of consequence take place, the apparent ones would be so great, that we cannot form any idea of the face which nature would then present to us. See ASTRONOMY.

In geography the circles which the sun apparently describes in the heavens are supposed to be extended as far as the earth, and marked on its surface; and in like manner we may imagine as many circles as we please to be described on the earth, and their planes to be extended to the celestial sphere, till they mark concentric ones on the heavens. The most remarkable of those supposed by geographers to be described in this manner are the following.

1. *The horizon*. This is properly a double circle, one of the horizons being called the sensible, and the other the rational. The former comprehends only that space which we can see around us upon any part of the earth, and which is very different according to the difference of our situation. The other, called the rational, is a circle parallel to the former, and passing through the centre of the earth, supposed to be continued as far as the celestial sphere itself. To the eyes of spectators there is always a vast difference between the sensible and rational horizons; but from the immense disparity betwixt the size of the earth and celestial sphere, planes of both circles may be considered as coincident. Hence in geography, when the horizon, or plane of the horizon, is spoken of, the rational is always understood when nothing is said to the contrary. In consequence of the round figure of the earth, every part has a different horizon. The poles of the horizon, that is, the points directly above the head, and opposite to the feet of the observer, are called the zenith and nadir.

2. A great circle described upon the sphere of the heaven, and passing through the two vertical points, is called a vertical circle, or an azimuth; and of these we may suppose as many as we please all round the horizon. In geography every circle obtains the epithet of great whose plane passes through the centre of the earth; in other cases they are called lesser circles. The altitudes of the heavenly bodies are measured by an arch of the azimuth or vertical circle intercepted between the horizon and the body itself. The most accurate method of taking them, with regard to the sun and moon, is for two persons to make their observations at the same time; one of them to observe the altitude of the upper limb, the other of the lower limb of the luminary; the mean betwixt these two giving the true height of the centre. The same thing may also be done accurately by one observer, having the apparent diameter of the luminary given. For, having found the height of the upper edge of the limb by the quadrant, take from it half his diameter, the remainder is the height of his centre; or having found the altitude

of his lower edge, add to it half the diameter, and the sum is the height of the centre as before. When the observations are made with a large instrument, it will be convenient to use a sextant, or sixth part of a circle, rather than a quadrant, as being less unwieldly.

3. Almucantars are circles supposed to be drawn upon the sphere parallel to the horizon, and grow less and less as they approach the vertical points, where they entirely vanish. The apparent distances betwixt any two celestial bodies are measured by supposing arches of great circles drawn through them, and then finding how many degrees, minutes, &c. of these circles are intercepted between them.

4. Sometimes the visible horizon is considered only with regard to the objects which are upon the earth itself, in which case we may define it to be a lesser circle on the surface of the earth, comprehending all such objects as are at once visible to us; and the higher the eye, the more is the visible horizon extended. It is most accurately observed, however, on the sea, on account of the absence of those inequalities which at land render the circle irregular; and for this reason it is called sometimes the horizon of the sea, and may be observed by looking through the sights of a quadrant at the most distant part of the sea then visible.

5. The equator is a great circle upon the earth, every part of which is equally distant from the poles or extremities of the imaginary line on which the earth revolves. In the sea-language it is usually called the line, and when people sail over it they are said to cross the line.

6. The meridian of any place is a great circle on the earth drawn through that place and both poles of the earth. It cuts the horizon at right angles, marking upon it the true north and south point; dividing also the globe into two hemispheres, called the eastern and western from their relative situation to that place and to one another. The poles divide the meridians into two semicircles, one of which is drawn through the place to which the meridian belongs, the other through that point of the earth which is opposite to the place. By the meridian of a place, geographers and astronomers often mean that semicircle which passes through the place, and which may therefore be called the geographical meridian. All places lying under this semicircle are said to have the same meridian; the semicircle opposite to this is called the opposite meridian. The meridians are thus immovably fixed to the earth as much as the places themselves on its surface, and are carried along with it in its diurnal rotation. When the geographical meridian of any place is, by the rotation of the earth, brought to point at the sun, it is noon or mid-day at that place; in which case, was the plane of the circle extended, it would pass through the middle of the luminary's disk. Supposing the plane of the meridians to be extended to the sphere of the fixed stars, in that case, when by the rotation of the earth the meridian comes to any point in the heavens, then, from the apparent motion of the heavens, that point is said to come to the meridian. The rotation of the earth is from west to east; whence the celestial bodies appear to move the contrary way. East and west, however, are terms merely relative, since a place may be west from one part of the earth, and east from another; but the true east and west points from any place are those where its horizon cuts the equator.

7. All places lying under the same meridian are said to have the same longitude, and those which lie under different meridians to have different longitudes; the difference of longitude being reckoned eastward or westward on the equator. Thus, if the meridian of any place cuts the equator in a point 15 degrees distant from one another, we say there is a difference of 15° longitude betwixt these two places. Geographers usually fix upon the meridian of some remarkable place for the first meridian, and reckon the longitude of all others by the distance of their meridians from which they have determined upon as the first; measuring sometimes eastward on the equator all round the globe, or sometimes only one-half east and the other west; according to which last measurement no place can have more than 180° longitude either east or west. By the ancient Greek geographers the first meridian was placed in Hera or Junonia, one of the Fortunate Islands, as they were then called, which is supposed to be the present island of Teneriffe, one of the Canaries. These islands, being the most westerly part of the earth then known, were on that account made the seat of the first meridian, the longitude of all other places being counted eastward from them. Among modern geographers indeed, it is now become customary for each to make the first meridian pass through the capital of his own country; a practice, however, which is certainly improper, as it is thus impossible for the geographers of one nation to understand the maps of another without a troublesome calculation, which answers no purpose. By the British geographers the royal observatory at Greenwich is accounted the place of the first meridian.

8. If we suppose 12 great circles, one of which is the meridian to a given place, to intersect each other at the poles of the earth, and divide the equator into 24 equal parts, these are the hour-circles of that place. These are by the poles divided into 24 semicircles, corresponding to the 24 hours of the day and night. The distance betwixt each two of these semicircles is 15°, being the 24th part of 360; and by the rotation of the earth each succeeding semicircle points at the sun one hour after the preceding: so that in 24 hours all the semicircles point successively at the sun. Hence it appears, that such as have their meridian 15° east from any other have likewise noon one hour sooner, and the contrary; and in like manner every other hour of the natural day is an hour sooner at the one place than at the other. Hence, from any instantaneous appearance in the heavens observed at two distant places, the difference of longitude may be found, if the hour of the day is known at each place. Thus the beginning of an eclipse of the moon, when the luminary first touches the shadow of the earth, is an instantaneous appearance, as also the end of an eclipse of this kind, when the moon leaves the shadow of the earth visible to all the inhabitants on that side of the globe. If therefore we find, that at any place an eclipse of the moon begins an hour sooner than at another, we conclude that there is a difference of 15° of longitude between the two places. Hence also was a man to travel or sail round the world from west to east, he would reckon one day more to have passed than they do who stay at the place

whence he set out; so that their Monday would be his Tuesday, &c. On the other hand, if he sails westward, he will reckon a day less, or be one day in the week later, than those he leaves behind.

9. The equator divides the earth into two hemispheres, called the northern and southern; all places lying under the equator are said to have no latitude; and all others to have north or south latitude, according to their situation with respect to the equator. The latitude itself is the distance from the equator measured upon the meridian, in degrees, minutes, and seconds. The complement of latitude is the difference between the latitude itself and 90°, or as much as the place itself is distant from the pole; and this complement is always equal to the elevation of the equator above the horizon of the place. The elevation of the pole of any place is equal to the latitude itself.

An inhabitant of the earth who lived (if it was possible) at either of the poles would have always one of the celestial poles in his zenith, and the other in his nadir, the equator coinciding with the horizon. Hence all the celestial parallels are also parallel to the horizon; whence the person is said to live in a parallel sphere, or to have a parallel horizon.

Those who live under the equator have both poles in the horizon, all the celestial parallels cutting the horizon at right angles; whence they are said to live in a right sphere, or to have a right horizon.

Lastly, those who live between either of the poles and the equator, are said to live in an oblique sphere, or to have an oblique horizon, because the celestial equator cuts their horizon obliquely, and all the parallels in the celestial sphere have their planes oblique to that of the horizon. In this sphere some of the parallels intersect the horizon at oblique angles, some are entirely above it; and some are entirely below it; all of them, however, so situated, that they would obliquely intersect the plane of the horizon extended.

The largest parallel which appears entire above the horizon of any place in north latitude is called by the ancient astronomers the arctic circle of that place; within this circle, that is, between it and the arctic pole, are comprehended all the stars which never set in that place, but are carried perpetually round the horizon in circles parallel to the equator. The largest parallel which is hid entirely below the horizon of any place in north latitude was called the antarctic circle of that place by the ancients. This circle comprehends all the stars which never rise in that place, but are carried perpetually round below the horison in circles parallel to the equator. In a parallel sphere, however, the quator may be considered as both arctic and antarctic circle; for, being coincident with the horizon, all the parallels on one side are entirely above it, and those on the other entirely below it. In an oblique sphere, the nearer any place is to either of the poles, the larger are the arctic and antarctic circles, as being nearer to the celestial equator, which is a great circle. In a right sphere, the arctic and antarctic circles have no place, because no parallel appears either entirely above or below it. By the arctic and antarctic circles, however, modern geographers in general understand two fixed circles at the distance of 23½ degrees from the pole. These are supposed to be described by the poles of the ecliptic, and mark out the space all round the globe where the sun appears to touch the horizon at midnight in the summer time, and to be entirely sunk below it in the winter. These are also called the polar circles.

According to the different positions of the globe with regard to the sun, the celestial bodies will exhibit different phenomena to the inhabitants. Thus, in a parallel sphere, they will appear to move in circles round the horizon; in a right sphere they would appear to rise and set as at present, but always in circles, cutting the horizon at right angles; but in an oblique sphere the angle varies according to the degree of obliquity, and the position of the axis of the sphere with regard to the sun. Hence we easily perceive the reason of the sun's continual change of place in the heavens; but though it is certain that this change takes place every moment, the vast distance of the luminary renders it imperceptible for some time, unless to very nice astronomical observers. Hence we may generally suppose the place of the sun to be the same for a day or two together, though in a considerable number of days it becomes exceedingly obvious to every body. When he appears in the celestial equator, his motion appears for some time to be in the plane of that circle, though it is certain that his place there is only for a single moment; and in like manner, when he comes to any other point of the heavens, his apparent diurnal motion is in a parallel drawn throughout. Twice a year he is in the equator, and then the days and nights are nearly equal all over the earth. This happens in the months of March and September; after which the sun proceeding either northward or south, according to the season of the year and the position of the observer, the days become longer or shorter than the nights, and summer or winter comes on, as is fully explained under the article ASTRONOMY. The secession of the sun from the equator either northward or southward is called his declination, and is either north or south according to the season of the year; and when this declination is at its greatest height, he is then said to be in the tropic, because he begins to turn back (the word tropic being derived from the Greek τρεπω, verto.) The space between the two tropics, called the torrid zone, extends for no less than 47 degrees of latitude all round the globe; and throughout the whole of that space the sun is vertical to some of the inhabitants twice a year, but to those who live directly under the tropics only once. Throughout the whole torrid zone also there is little difference between the length of the days and nights. The ancient geographers found themselves considerably embarrassed in their attempts to fix the northern tropic; for though they took a very proper method, namely, to observe the most northerly place where objects had no shadow on a certain day, yet they found that on the same day no shadow was cast for a space of no less than 300 stadia. The reason of this was, the apparent diameter of the sun, which, being about half a degree, seemed to extend himself over as much of the surface of the earth, and to be vertical every where within that space.

When the sun is in or near the equator, he seems to change his place in the heavens most rapidly; so that about the equinoxes one may very easily perceive the difference in a day or two; but as he approaches the tropics,

this apparent change becomes gradually slower, so that for a number of days he scarcely seems to move at all. The reason of this may easily be understood from any map on which the ecliptic is delineated; for by drawing lines through every degree of it parallel to the equator, we shall perceive them gradually approach nearer and nearer each other, until at last, when we approach the point of contact betwixt the ecliptic and tropic, they can for several degrees scarcely be distinguished at all.

From an observation of the diversity in the length of the days and nights, the rising and setting of the sun, with the other phenomena already mentioned, the ancient geographers divided the surface of the earth into certain districts, which they called climates; and instead of the method of describing the situation of places by their latitude and longitude as we do now, they contented themselves with mentioning the climate in which they were situated.

This method of dividing the surface of the earth into climates, though now very much disused, has been adopted by several modern geographers. Some of these begin their climates at the equator, reckoning them by the increase of half an hour in the length of the day northward. Thus they go on till they come to the polar circles, where the longest day is 24 hours: betwixt these and the poles they count the climates by the increase of a natural day in the length of time that the sun continues above the horizon, until they come to one where the longest day is 15 of ours, or half a month; and from this to the pole they count by the increase of half-months or whole months, the climates ending at the poles where the days are six months long. The climates betwixt the equator and the polar circles are called hour-climates, and those between the polar circles and the poles are called month-climates. In common language, however, we take the word climate in a very different sense; so that when two countries are said to be in different climates, we understand only that the temperature of the air, seasons, &c. are different.

From the difference in the length and positions of the shadows of terrestrial substances, ancient geographers have given different terms to the inhabitants of certain places of the earth; the reason of which will be easily understood from the following considerations: 1. Since the sun in his apparent annual revolution never removes farther from the equator than $23\frac{1}{2}$ degrees, it follows, that none of those who live without that space, or beyond the tropics, can have the luminary vertical to them at any season of the year. 2. All who live between the tropics have the sun vertical twice a year, though not all at the same time. Thus, to those who live directly under the equator, he is directly vertical in March and September at the time of the equinox. If a place is in 10° north latitude, the sun is vertical when he has 10° north declination, and so of every other place. 3. All who live between the tropics have the sun at noon sometimes north and sometimes south of them. Thus those who live in a place situated in 20° north latitude have the sun at noon to the northward when he has more than 20 degrees north declination, and to the southward when he has less. 4. Such of the inhabitants of the earth as live without the tropics, if in the northern hemisphere, have the sun at noon to the southward of them, but to the northward if in the southern hemisphere. 1. Hence when the sun is in the zenith of any place, the shadow of a man or any upright object falls directly upon the place where they stand, and consequently is invisible; whence the inhabitants of such places were called Ascii, or without shadows. 2. Those who live between the tropics, and have the sun sometimes to the north and sometimes to the south of them, have of consequence their shadows projecting north at some seasons of the year, and south at others, whence they were called Amphiscii, or having two kinds of shadows. 3. Those who live without the tropics have their noon-shadows always the same way, and are therefore called Heteroscii, that is, having only one kind of shadow. If they are in north latitude, the shadows are always turned towards the north, and if in the southern hemisphere, towards the south. 4. When a place is so far distant from the equator that the days are 24 hours long, or longer, the inhabitants were called Periscii, because their shadows turn round them.

Names have likewise been imposed upon the inhabitants of different parts of the earth from the parallels of latitude under which they live, and their situation with regard to one another. 1. Those who lived at distant places, but under the same parallel, were called Periæci, that is, living in the same circle. Some writers, however, by the name of Periæci distinguish those who live under opposite points of the same parallel, where the noon of one is the midnight of the other. 2. When two places lie under parallels equally distant from the equator, but in opposite hemispheres, the inhabitants were called Antæci. These have a similar increase of days and nights, and similar seasons, but in opposite months of the year. According to some, the Antæci were such as lived under the same geographical meridian, and had day and night at the same time. 3. If two places are in parallels equally distant from the equator, and in opposite meridians, the inhabitants were called Antipodes, that is, having their feet opposite to one another. When two persons are Antipodes, the zenith of the one is the nadir of the other. They have a like elevation of the pole, but it is of different poles; they have also days and nights alike, and similar seasons of the year, but they have opposite hours of the day and night, as well as seasons of the year. Thus, when it is mid-day with us, it is midnight with our Antipodes; when it is summer with us, it is winter with them, &c.

From the various appearances of the sun, and the effects of his light and heat upon different parts of the earth, the division of it into zones has arisen. These are five in number. 1. The torrid zone, lying between the two tropics for the space of 47° of latitude. This is divided into two equal parts by the equator. 2. The two temperate zones lie between the polar circles and the tropics, containing a space of 43° of latitude. And, 3. The two frigid zones lie between the polar circles and the poles. In these last the longest day is never below 24 hours; in the temperate zones it is never quite so much, and in the torrid zone it is never above 14. The zones are named from the degree of heat they were supposed to be subjected to. The torrid zone was supposed by the ancients to be uninhabitable, on account of its heat; but this is now found to be a mistake, and many parts of the temperate zones are more intolerable in this respect than

the torrid zone itself. Towards the polar circles also these zones are intolerably cold during the winter season. Only a small part of the northern frigid zone, and none of the southern, is inhabited. Some geographers reckoned six zones, dividing the torrid zone into two by the equator.

Besides these there are other technical terms belonging to geography which it is necessary to explain; some of these have relation to the earth, and others to the water.

A *continent* is a large portion of the earth, which comprehends several countries that are not separated by any sea; such are Europe, Asia, Africa, and America. An *island* is a part of the earth which is entirely surrounded by water; as Great Britain. A *peninsula* is a tract of land almost surrounded with water, and is joined to a continent only by a narrow slip or neck; such is the Morea in Greece. An *isthmus*, or neck of land, is that part by which a peninsula is joined to a continent, or two continents together; as the isthmus of Suez, which joins Africa to Asia. A *promontory*, or cape, is a high part of land which stretches into the sea; thus the Cape of Good Hope is a promontory. An *ocean* is a vast collection of waters surrounding a considerable part of the continent; as the Atlantic. A *sea* is a smaller collection of waters; as the Black Sea. A *gulf* is a part of the sea which is nearly surrounded with land; as the gulf of Venice. A *bay* has a wider entrance than a gulf; as the Bay of Biscay. A *strait* is a narrow passage that joins two seas; as the Strait of Gibraltar, which joins the Mediterranean to the Atlantic. A *lake* is a large collection of water entirely surrounded by land, having no visible communication with the sea; as the Caspian Lake in Asia. A *river* is a stream of water that has its source from a spring, which keeps constantly running till it falls into some other river, or into the sea.

In a popular point of view, geography admits of three divisions: 1. The ancient or classical, which describes the state of the earth, not extending farther than the 500th year of the Christian æra. 2. That of the middle ages, which reaches to the 15th century, when the discoveries of the Portuguese began to lay broader foundations for this science. 3. Modern geography, the chief object of which is to present the most recent and authentic information concerning the nations and states which divide and diversify the earth. In some instances natural barriers have divided, and continue to divide, nations; but in general the boundaries are arbitrary, so that the natural geography of a country may be regarded as a sequel to the science, which is chiefly occupied in describing the diversities of nations, and the conditions of the various races of mankind.

The ancients considered the globe under the three grand divisions of Asia, Europe, and Africa. Here the distinctions were arbitrary, as they often included Egypt under Asia, and they had not discovered the limits of Europe towards the N. E. Modern discoveries have added a fourth division, that of America, which exceeding even Asia in size, might have been admitted under two grand and distinct denominations, limited by the isthmus of Darien. Till within these last 30 years it was supposed that a vast continent existed in the south of the globe; but the second navigation of Capt. Cook dispelled the idea, and demonstrated, that if any continent existed there, it must be in the uninhabitable ice of the south pole. The vast extent of New Holland rewarded the views of enterprise; this, which seems too large to be ranked among islands, and two small for a continent, eludes the petty distinctions of man: and while geographers hesitate whether to ascribe it to Asia, or to denominate it a fifth specific division of the earth, it is not improbable that the popular division of four quarters will still predominate over all speculative discussions.

Of the grand divisions of the earth, Asia has ever been esteemed the most populous; and is supposed to contain five hundred millions of souls, if China, as has been averred by the latest writers, comprizes three hundred and thirty millions. The population of Africa may be estimated at thirty millions, of America at thirty millions, and one hundred and sixty millions may perhaps be assigned to Europe.

Modern discoveries have evinced that more than two thirds of the globe is covered with water, which is contained in hollow spaces, or concavities, more or less large. But the chief convexities or protuberances of the globe consist of elevated uplands, sometimes crowned by mountains, sometimes rather level, as the extensive protuberance of Asia. In either case, long chains of mountains commonly proceed from those chief convexities in various directions, and the principal rivers usually spring from the most elevated grounds.

The grandest concavity of this globe is filled by the Pacific Ocean; occupying nearly half its surface from the eastern shores of New Holland, to the western coast of America, and diversified with several groups of islands, which seem in a manner the summits of vast mountains emerging from the waves. This ocean receives but few rivers, the chief being the Amur from Tartary, the Hoan Ho and Kian Ku from China, while the principal rivers of America run towards the east.

Next to this in magnitude is the Atlantic, between the Old and New Continents; and the third is the Indian Ocean. The seas between the arctic and antarctic circles and the poles, have been sometimes styled the Arctic and Antarctic Oceans; but the latter is only a continuation of the Pacific, Atlantic, and Indian Oceans; while the Arctic Sea is partly embraced by continents, and receives many important rivers. Besides these, there are other seas more minute, as the Mediterranean, the Baltic, and others still smaller, till we come by due gradation to inland lakes of fresh water.

The courses of rivers are sometimes marked by oblong concavities, which generally at first intersect the higher grounds, till the declivity becomes more gentle on their approach towards their inferior receptacles. But even large rivers are found sometimes to spring from lowland marshes, and wind though vast plains, unaccompanied by any concavity, except that of their immediate course; while on the other hand, extensive vales, and low hollow spaces, frequently occur destitute of any stream. Rivers will also sometimes force a passage where nature has erected mountains and rocks against it, and where the concavity would appear to be in another direction, which the river might have gained with more ease. In like manner, though the chief mountains of Europe extend in a south-easterly direction, yet there are so many exceptions, and such numerous and impor-

tant variations in other parts of the globe, as to render any attempt at general theory vain.

From the vast expanse of oceanic waters, arises in the ancient hemisphere, that wide continent, which contains Asia, Europe, and Africa; and in the modern hemisphere the continent of America, which forms a kind of separate island, divided by a strait of the sea from the ancient continent. In the latter many discoveries of great importance to geography, are of very modern date, and it is not above 60 years since we obtained an imperfect idea of the extent of Siberia and the Russian empire, nor above 25 since ample, real, and accurate knowledge of these wide regions began to be diffused. So that, in truth, America may be said to have been discovered before Asia; and of Africa our knowledge continues imperfect, while the latest observations, instead of diminishing, rather increase our idea of its extent.

But the grandest division of the ancient continent is Asia, the parent of nations, and of civilization: on the north-east and south, surrounded by the ocean; but on the west, divided by an ideal line from Africa; and from Europe by boundaries not very strongly impressed by the hand of nature. The Russian and the Turkish empires, extending over large portions of both continents, intimately connect Asia with Europe. But for the sake of clearness and precision, geographers retain the strict division of the ancient continent into three parts, which, if not strictly natural, is ethical, as the manners of the Asiatic subjects of Russia, and even of Turkey, differ considerably from those of the European inhabitants of those empires.

A description of the four quarters of the globe, and of the several kingdoms and states into which they are divided, belongs rather to a work devoted exclusively to geography, than to a dictionary of arts and sciences: we shall therefore forbear entering more into detail in this article.

GEOLOGY, a science which treats of the decomposition and changes to which the stony part of our globe has been subjected.

If it was permitted to man to follow, during several ages, the various changes which are produced on the surface of our globe by the numerous agents that alter it, we should at this time have been in possession of the most valuable information respecting these great phenomena: but thrown as we are, almost by accident, upon a small point of this vast theatre of observation, we fix our attention for a moment upon operations which have been the work of nature for ages; and we are unable either to perceive or to foretel the results, because several ages are scarcely sufficient to render the effects or changes perceptible.

It must be allowed that those men who, by the mere efforts of their imagination, have endeavoured to form ideas respecting the construction, and the great phenomena, of this globe, have numerous titles to our indulgence. In their proceedings we behold the efforts of genius, tormented with the desire of acquiring knowledge, and irritated at the prospect of the scanty means which nature has put in its power; and when these naturalists, such as M. de Buffon, have possessed the power of embellishing their hypotheses with every ornament which imagination and eloquence can furnish, either as instruments of illusion or entertainment, we ought to consider ourselves indebted to them.

For our part, we shall confine ourselves to a few ideas respecting the successive decompositions of our planet, and shall endeavour to avoid every departure from observation and matter of fact.

The slightest observation shows us that living beings are kept up and perpetuated only by successive decompositions and combinations. A slight view of the mineral kingdom exhibits the same changes; and our globe, in all its productions, presents continual modifications, and a circle of activity, which might appear incompatible with the apparent inertia of earthy products.

In order to arrange our ideas with greater regularity, we may consider this globe in two different states. We shall first examine the primitive rock which forms the nodule or central part. This appears to contain no germ of life; includes no remains or part of any living being; and from every circumstance appears to have been of primitive formation, anterior to the creation of animated or vegetating bodies. We shall pursue the various changes which are daily produced by the destructive action of such agents as alter or modify this substance.

We shall then proceed to examine what stones have been successively placed upon this, and what are the decompositions to which these secondary rocks have been subjected.

1. The observations of naturalists all unite to prove that the primitive part of the globe consists of the stone known by the name of granite. The profound excavations which the art of man, or currents of water, have made in the surface of our planet, have all uncovered this rock, and have been incapable of penetrating lower: we may therefore consider this substance as the nucleus of the globe; and upon this substance it is that all matters of posterior formation rest.

Granite exhibits many varieties in its form, composition, and disposition: but it in general consists of an assemblage of certain siliceous stones, such as quartz, schorl, feldtspar, mica, &c.; and the more or less considerable magnitude of these elements of granite, has caused it to be divided into coarse-grained granite, and fine-grained granite.

It is thought that these rocks owe their arrangement to water; and if we may be permitted to recur, by an effort of the imagination, to that epocha in which, according to sacred and profane historians, the water and earth were confounded, and the confused mixture of all principles formed a choas, we shall see that the laws of gravity inherent in matter must have carried it down, and necessarily produced the arrangement which observation at present exhibits to us. The water, as the least heavy, must have purified itself, and arisen to the surface by a filtration through the other materials: while the earthy principles must have precipitated, and formed a mud, in which all the elements of stones were confounded. In this very natural order of things, the general law of affinities, which continually tends to bring together all analogous parts, must have exerted itself with its whole activity upon the principles of this almost fluid paste; and the result have been a number of bodies of a more definite kind, in crystals more or less regular; and from this muddy substance, in which the principles of the stones

were confounded that compose the granite, a rock must have been produced, containing the elementary stones, all in possession of their distinct forms and characters. In this manner it is that we observe salts of very different kinds develope themselves in waters which hold them in solution; and in this manner it still happens that crystals of spar and gypsum are formed in clays which contain their component parts.

It may easily be conceived that the laws of gravitation must have influenced the arrangement and disposition of the products. The most gross and heavy bodies must have fallen, and the lightest and most attenuated substances must have arranged themselves on the surface of the foregoing; and this it is which constitutes the primitive schisti, the gneis, the rocks of mica, &c. which commonly repose upon masses of coarse-grained granite.

The disposition of the fine-grained granite in strata or beds, appears to depend on this position, and the fineness or tenuity of its parts. Being placed in immediate contact with water, this fluid must naturally have influenced the arrangement which it presents to us; and the elements of this rock being subjected to the effect of waves, and the action of currents, must have formed strata.

The rocks of granite being once established as the nucleus of our globe, we may, from the analysis of its constituent principles, and by attending to the action of the various agents capable of altering it, follow the changes to which it has been subjected, step by step.

Water is the principal agent whose effects we shall examine.

This fluid, collected in the cavity of the ocean, is carried by the atmosphere to the tops of the most elevated mountains, where it is precipitated in rain, and forms torrents, which return with various degrees of rapidity into this common reservoir.

This uninterrupted motion and fall must gradually attenuate and wear away the hardest rocks, and carry their detached parts to distances more or less considerable. The action of the air, and the varying temperature of the atmosphere, facilitate the attenuation and the destruction of these rocks. Heat acts upon their surface, and renders it more accessible and more penetrable to the water which succeeds; cold divides them, by freezing the water which has entered into their texture; the air itself affords the acid principle, which attacks the limestone, and causes it to effloresce; the oxygen unites to the iron, and calcines it: insomuch that this concurrence of causes favours the disunion of principles; and consequently the action of water, which clears the surface, carries away the products of decomposition, and makes preparation for a succeeding process of the same nature.

The first effect of the rain is therefore to depress the mountains. But the stones which compose them must resist in proportion to their hardness; and we ought not to be surprised when we observe peaks which have braved the destructive action of time, and still remain to attest the primitive level of the mountains which have disappeared. The primitive rocks, alike inaccessible to the injury of ages as to the animated beings which cover less elevated mountains with their remains, may be considered as the source or origin of rivers and streams. The water which falls on their summits, flows down in torrents by their lateral surfaces. In its course it wears away the soil upon which it incessantly acts. It hollows out a bed, of a depth proportioned to the rapidity of its course, the quantity of its waters, and the hardness of the rock over which it flows; at the same time that it carries along with it portions and fragments of such stones as it loosens in its course.

These stones, rolled along by the water, must strike together, and break off their projecting angles: a process that must quickly have afforded those rounded flints which form the beds of rivers. These pebbles are found to diminish in size, in proportion to the distance from the mountain which affords them; and it is to this cause that Mr. Dorthes has referred the disproportionate magnitude of the pebbles which form our ancient worn stones, when compared with those of modern date; for the sea extending itself formerly much more inland, in the direction of the Rhone, the stones which it received from the rivers, and threw back again upon the shores, had not run through so long a space in their beds as those which they at present pass over. Thus it is that the remains of the Alps, carried along by the Rhone, have successively covered the vast interval comprised between the mountains of Dauphiny and Vivaris; and are carried into seas, which deposit them in small pebbles on the shore.

The pulverulent remains of mountains, or the powder which results from the rounding of these flints, are carried along with greater facility than the flints themselves: they float for a long time in the water, whose transparency they impair; and when these same waters are less agitated, and their course becomes slackened, they are deposited in a fine and light paste, forming beds more or less thick, and of the same nature as that of the rocks to which they owe their origin. These strata gradually become drier by the agglutination of their principles; they become consistent, acquire hardness, and form silecious clays, silex, petrosilex, and all the numerous class of pebbles which are found dispersed in strata, or in banks, in the ancient beds of rivers.

The mud is much more frequently deposited in the interstices left between the rounded flints themselves, which intervals it fills, and there forms a true cement that becomes hard, and constitutes the compound stones known by the name of pudding-stones and grit-stones; for these two kinds of stones do not appear to differ but in the coarseness of the grain which forms them, and the cement which connects them together.

We sometimes observe the granite spontaneously decomposed. The texture of the stones which form it has been destroyed; the principles or component parts are disunited and separated, and they are gradually carried away by the waters.

Water filtrating through mountains of primitive rock, frequently carries along with it very minutely divided particles of quartz; and proceeds to form, by deposition, stalactites, agates, rock crystal, &c.

These quartzose stalactites, differently coloured, are of a formation considerably analogous to that of calcareous alabasters; and we perceive no other difference between them than that of their constituent parts.

II. Thus far we have exhibited, in a few words, the principal changes, and various modifications, to which the primitive rocks have been subjected. We have not yet observed either germination or life; and the metals.

sulphur, and bitumens, have not hitherto presented themselves to our observation. Their formation appears to be posterior to the existence of this primitive globe; and the alterations and decompositions which now remain to be inquired into, appear to be produced by the class of living, or organized beings.

On the one hand, we behold the numerous class of shell animals, which cause the stony mass of our globe to increase by their remains. The spoils of these creatures, long agitated and driven about by the waves, and more or less altered by collision, form those strata and banks of limestone, in which we very often perceive impressions of those shells to which they owe their origin.

On the other hand, we observe a numerous quantity of vegetables that grow and perish in the sea; and these plants likewise, deposited and heaped together by the currents, form strata, which are decomposed, lose their organization, and leave all the principles of the vegetable confounded with the earthy principle. It is to this source that the origin of pit-coal, and secondary schistus, is usually attributed; and this theory is established on the existence of the texture of decomposed vegetables very usually seen in schisti and coal, and likewise on the presence of shells and fish in most of these products.

It appears that the formation of pyrites ought in part to be attributed to the decomposition of vegetables: it exists in greater or less abundance in all schisti and coal. A wooden shovel has been found buried in the depositions of the river De Ceze, converted into jet and pyrites. The decomposition of animal substances may be added to this cause; and it appears to be a confirmation of these ideas, that we find many shells passed to the state of pyrites.

Not only the marine vegetables form considerable strata by their decomposition; but the remains of those which grow on the surface of the globe ought to be considered among the causes or agents which concur in producing changes upon that surface.

We shall separately consider how much is owing to each of these causes; and shall follow the effects of each, as if that cause alone was employed in modifying and altering our planet.

1. The secondary calcareous mountains are constantly placed upon the surface of the primitive mountains; and though a few solitary observations present a contrary order, we ought to consider this inversion and derangement as produced by shocks which have changed the primitive disposition. It must be observed also, that the disorder is sometimes merely apparent; and that some naturalists of little information have described calcareous mountains as inclining beneath the granite, because this last pierces through the envelope, rises to a greater height, and leaves at its feet, almost beneath it, the calcareous remains deposited at its base.

Sometimes even the limestone fills to a very great depth the crevices or clefts formed in the granite. The writer of this article has seen in Gevaudan, towards Florac, a profound cavity in the granite filled with calcareous stone. This vein is known to possess a depth of more than 150 fathoms, with a diameter of about two or three.

It likewise happens frequently enough that such waters as are loaded with the remains of the primitive granite, heap them together, and form secondary granites, which may exist above the calcareous stone.

The secalcareous mountains are decomposed by the combined action of air and water; and the product of their decomposition sometimes forms chalk or marle.

The lightness of this earth renders it easy to be transported by water; and this fluid, which does not possess the property of holding it in solution, soon deposits it in the form of gurhs, alabasters, stalactites, &c. Spars owe their formation to no other cause. Their crystallization is posterior to the origin of calcareous mountains.

Waters wear down and carry away calcareous mountains with greater ease than the primitive mountains: their remains being very light, are rolled along, and more or less worn. The fragments of these rocks are sometimes connected by a gluten or cement of the same nature; from which process calcareus grit and breccias arise. These calcareous remains formerly deposited themselves upon the quartzose sand; and the union of primitive matter, and secondary products, gives rise to a rock of mixed nature.

2. The mountains of secondary schistus frequently exhibit to us a pure mixture of earthy principles, without the smallest vestige of bitumen. These rocks afford, by analysis, silex, alumina, magnesia, lime in the state of carbonate, and iron: principles which are more or less united, and consequently accessible in various degrees to the action of such agents as destroy the rocks hitherto treated of.

The same principles, when disunited, and carried away by waters, give rise to a great part of the stones which are comprised in the magnesian class. The same elements, worn down by the waters, and deposited under circumstances proper to facilitate crystallization, form the schorls, tourmaline, garnets, &c.

We do not pretend by this to exclude and absolutely reject the system of such naturalists as attribute the formation of magnesian stones to the decomposition of the primitive rocks. But we think that this formation cannot be objected to for several of them, more especially such as contain magnesia in the greatest abundance.

It frequently happens that the secondary schisti are interspersed with pyrites; and, in this case, the simple contact of air and water facilitates their decomposition. Sulphuric acid is thus formed, which combines with the various constituent principles of the stone; whence result the sulphate of iron, of magnesia, of alumina, and of lime, which effloresce at the surface, and remains confounded together. Schisti of this nature are wrought in most places where alum-works have been established; and the most laborious part of this undertaking consists in separating the sulphates of iron, of lime, and of magnesia from each other, which are mixed together. Sometimes the magnesia is so abundant that its sulphate predominates. The sulphate of lime, being very sparingly soluble in water, is carried away by that liquid, and deposited to form gypsum; while the other more soluble salts, remaining suspended, form vitriolic mineral waters.

The pyritous schisti are frequently impregnated with bitumen, and the proportions constitute the various qualities of pit-coal.

It appears that we may lay it down as an incontestable principle, that the pyrites is abundant is proportion as

the bituminous principle is more scarce. Hence it arises, that coals of a bad quality are the most sulphureous, and destroy metallic vessels, by converting them into pyrites. The foci of volcanos appear to be formed by a schistus of this nature; and in the analyses of the stony matters which are ejected, we find the same principles as those which constitute this schistus. We ought not therefore to be much surprised at finding schorls among volcanic products; and still less at observing that subterranean fires throw sulphuric salts, sulphur, and other analogous products, out of the entrails of the earth.

3. The remains of terrestrial vegetables exhibit a mixture of primitive earths more or less coloured by iron: we may therefore consider these as a matrix in which the seeds of all stony combinations are dispersed. The earthy principles assort themselves according to the laws of their affinities; and form crystals of spar, of plaister, and even the rock crystals, according to all appearance: for we find ochreous earths in which these crystals are abundantly dispersed; we see them formed almost under our eyes. We have frequently observed indurated ochres full of these crystals terminating in two pyramids.

The ochreous earths appear to deserve the greatest attention of naturalists. They constitute one of the most fertile means of action which nature employs; and it is even in earths nearly similar to these that she elaborates the diamond, in the kingdoms of Golconda and Visapour.

The spoils of animals, which live on the surface of the globe, are entitled to some consideration among the number of causes which we assign to explain the various changes our planet is subjected to. We find bones in a state of considerable preservation in certain places; we can even frequently enough distinguish the species of the animals to which they have belonged. From indications of this sort it is that some writers have endeavoured to explain the disappearance of certain species; and to draw conclusions thence, either that our planet is perceptibly cooled, or that a sensible change has taken place in the position of the axis of the earth. The phosphoric salts and phosphorus which have been found, in our time, in combination with lead, iron, &c. prove that, in proportion as the principles are disengaged by animal decomposition, they combine with other bodies, and form the nitric acid, the alkalis, and in general all the numerous kinds of nitrous salts. See MINERALOGY.

GEOMETRICAL *lines*, as observed by Newton, are distinguished into classes, orders, or genera, according to the number of the dimensions of the equation that expresses the relation between the ordinates and abscisses; or, which becomes to the same thing, according to the number of points in which they may be cut by a right line.

Thus, a line of the first order, is a right line, since it can be only once cut by another right line, and is expressed by the simple equation $y + ax + b = 0$; those of the 2d, or quadratic order, will be the circle, and the conic sections, since all these may be cut in two points by a right line, and expressed by the equation $y^2 + \overline{ax + b} \,.\, y + cx^2 + dx + e = 0$; those of the 3d cubic order, will be such as may be cut in three points by a right line, whose most general equation is $y^3 + \overline{ax + b} \,.\, y^2 + \overline{cx^2 + dx + e} \,.\, y + fx^3 + gx^2 + bx + i = 0$; as the cubical parabola, the cissoid, &c. And a line of an infinite order, is that which a right line may cut in infinite points; as the spiral, the cycloid, the quadratrix, and every line that is generated by the infinite revolutions of a radius, or circle, or wheel, &c.

In each of those equations, x is the absciss, y its corresponding ordinate, making any given angle with it; and a, b, c, &c. are given or constant quantities, affected with their signs $+$ and $-$, of which one or more may vanish, be wanting or equal to nothing, provided that by such defect the line or equation does not become one of an inferior order.

It is to be observed that a curve of any kind is denominated by a number next less than the line of the same kind: thus, a curve of the first order (because the right line cannot be reckoned among curves), is the same with a line of the second order; and a curve of the second kind, the same with a line of the third order, &c.

It is to be observed also, that it is not so much the equation, as the construction or description, that makes any curve, geometrical, or not. Thus, the circle is a geometrical line, not because it may be expressed by an equation, but because its description is a postulate; and it is not the simplicity of the equation, but the easiness of the description, that is to determine the choice of the lines for the construction of a problem. The equation that expresses a parabola, is more simple than that which expresses a circle; and yet the circle, by reason of its more simple construction, is admitted before it. Again, the circle and the conic sections, with respect to the dimensions of the equations, are of the same order; and yet the circle is not numbered with them in the construction of problems, but by reason of its simple description is depressed to a lower order, viz. that of a right line; so that it is not improper to express that by a circle, which may be expressed by a right line; but it is a fault to construct that by the conic sections, which may be constructed by a circle.

GEOMETRICAL *solution* of a problem, is when the problem is directly resolved according to the strict rules and principles of geometry, and by lines that are truly geometrical. This expression is used in contradistinction to an arithmetical, or a mechanical, or instrumental solution; the problem being resolved only by a ruler and compasses.

The same term is likewise used in opposition to all indirect and inadequate kinds of solutions, as by approximation, infinite series, &c. So, we have no geometrical way of finding the quadrature of the circle, the duplicature of the cube, or two mean proportionals; though there are mechanical ways, and others by infinite series, &c.

Pappus informs us, that the ancients endeavoured in vain to trisect an angle and to find out two mean proportionals, by means of the right line and circle. Afterwards they began to consider the proprieties of several other lines; as the conchoid, the cissoid, and the conic sections; and by some of these they endeavoured to resolve some of those problems. At length, having more thoroughly examined the matter, and the conic sections being received into geometry, they distinguished geometrical problems and solutions into three kinds; viz.

1. Plane ones, which deriving their origin from lines

on a plane, may be properly resolved by a right line and a circle.

2. Solid ones, which are resolved by lines deriving their original from the consideration of a solid; that is, of a cone.

3. Linear ones, to the solution of which are required lines more compounded.

According to this distinction, we are not to resolve solid problems by other lines than the conic sections, especially if no other lines beside the right line, circle, and the conic sections, must be received into geometry.

But the moderns, advancing much farther, have received into geometry all lines that can be expressed by equations; and have distinguished, according to the dimensions of the equations, those lines into classes or orders; and have laid it down as a law, not to construct a problem by a line of a higher order, that may be constructed by one of a lower.

Geometrical progression, or proportion. See Algebra.

GEOMETRY, the science and doctrine of local extension, as of lines, surfaces, and solids, with that of ratios, &c.

The name geometry literally signifies measuring of the earth, as it was the necessity of measuring the land that first gave occasion to contemplate the principles and rules of this art, which has since been extended to numberless other speculations; insomuch that, together with arithmetic, geometry forms now the chief foundation of all the mathematics.

Herodotus and Proclus ascribe the invention of geometry to the Egyptians, and assert that the annual inundations of the Nile gave occasion to it; for those waters bearing away the bounds and landmarks of estates and farms, covering the face of the ground uniformly with mud, the people, say they, were obliged every year to distinguish and lay out their lands by the consideration of their figure and quantity; and thus by experience and habit they formed a method or art, which was the origin of geometry. A farther contemplation of the draughts of figures of fields, thus laid down and plotted in proportion, might naturally lead them to the discovery of some of their excellent and wonderful properties; which speculation continually improving, the art continually gained ground, and made advances more and more towards perfection.

Geometry is distinguished into theoretical or speculative, and practical.

Theoretical or speculative geometry, treats of the various properties and relations in magnitudes, demonstrating the theorems, &c. And

Practical geometry, is that which applies those speculations and theorems to particular uses in the solution of problems, and in the measurements in the ordinary concerns of life.

Speculative geometry again may be divided into elementary and sublime.

Elementary or common geometry, is that which is employed in the consideration of right lines and plane surfaces, with the solids generated from them. And the

Higher or sublime geometry, is that which is employed in the consideration of curve lines, conic sections, and the bodies formed of them. This part has been chiefly cultivated by the moderns, by help of the improved state of algebra, and the modern analysis or fluxions.

We shall now proceed to give the principles of practical geometry, beginning with

Definitions or explanations of terms.—1. A mathematical point has neither length, breadth, nor thickness. From this definition it may be easily understood that a mathematical point cannot be seen nor felt; it can only be imagined. What is commonly called a point, as a small dot made with a pencil or pen, or the point of a needle, is not in reality a mathematical point; for however small such a dot may be, yet if it be examined with a magnifying glass, it will be fround to be an irregular spot, of a very sensible length and breadth; and our not being able to measure its dimensions with the naked eye, arises only from its smallness. The same reasoning may be applied to every thing that is usually called a point; even the point of the finest needle appears like that of a poker when examined with the microscope.

2. A line is length without breadth or thickness. What was said above of a point, is also applicable to the definition of a line. What is drawn upon paper with a pencil or pen, is not in fact a line, but the representation of a line. For however fine you may make these representations, they will still have some breadth. But by the definition, a line has no breadth whatever, yet it is impossible to draw any thing so fine as to have no breath. A line therefore can only be imagined. The ends of a line are points.

3. Parallel lines are such as always keep at the same distance from each other, and which, if prolonged ever so far, would never meet. See Plate Geometry, fig. 1.

4. A right line is what is commonly called a straight line, or one that tends every where the same way.

5. A curve is a line which continually changes its direction between its extreme points.

6. An angle is the inclination or opening of two lines meeting in a point, fig. 2.

7. The lines AB, and BC, which form the angle, are called the legs or sides: and the point B, where they meet, is called the vertex of the angle, or the angular point. An angle is sometimes expressed by a letter placed at the vertex, as the angle B, fig. 2; but most commonly by three letters, observing to place in the middle the letter at the vertex, and the other two are those at the end of each leg, as the angle ABC.

8. When one line stands upon another, so as not to lean more to one side than to another, both the angles which it makes with the other are called right angles, as the angles ABC and ABD, fig. 3; and all right angles are equal to each other, being all equal to 90°; and the line AB is said to be perpendicular to CD.

Beginners are very apt to confound the terms perpendicular, and plumb or vertical line. A line is vertical when it is at right angles to the plane of the horizon, or level surface of the earth, or to the surface of water, which is always level. The sides of a house are vertical. But a line may be perpendicular to another, whether it stand upright, or inclines to the ground, or even if it lies flat upon it, provided only that it makes the two angles formed by meeting with the other line equal to each other; as for instance, if the angles ABC and ABD be

equal, the line AB is perpendicular to CD, whatever may be its position in other respects.

9. When one line BE (fig. 3), stands upon another, CD, so as to incline, the angle EBC, which is greater than a right angle, is called an obtuse angle; and that which is less than a right angle is called an acute angle, as the angle EBD.

10. Two angles which have one leg in common, as the angles ABC and ABE, are called contiguous angles, or adjoining angles; those which are produced by the crossing of two lines, as the angles EBD and CBF, formed by CD and EF, crossing each other, are called opposite or vertical angles.

11. A figure is a bounded space, and is either a surface or a solid.

12. A superficies, or surface, has length and breadth only. The extremities of a superficies are lines.

13. A plane, or plane surface, is that which is every where perfectly flat and even, or will touch every part of a straight line, in whatever direction it may be laid upon it. The top of a marble slab, for instance, is an example of this, which a straight edge will touch in every point, so that you cannot see light any where between.

14. A curved surface is that which will not coincide with a straight line in any part. Curved surfaces may be either convex or concave.

15. A convex surface is when the surface rises up in the middle; as, for instance, a part of the outside of a globe.

16. A concave surface is when it sinks in the middle, or is hollow, and is the contrary to convex.

A surface may be bounded either by straight lines, curved lines, or both these.

17. Every surface bounded by straight lines only is called a polygon. If the sides are all equal, it is called a regular polygon. If they are unequal, it is called an irregular polygon. Every polygon, whether equal or unequal, has the same number of sides as angles, and they are denominated sometimes according to the number of sides, and sometimes from the number of angles they contain. Thus a figure of three sides is called a triangle, and a figure of four sides a quadrangle.

A pentagon is a polygon of five sides; a hexagon has six sides; a heptagon seven sides; an octagon eight sides; a nonagon nine sides; a decagon ten sides; an undecagon eleven sides; a duodecagon twelve sides. See PENTAGON, &c.

When they have a greater number of sides it is usual to call them polygons of 13 sides, of 14 sides, and so on.

Triangles are of different kinds, according to the lengths of their sides.

18. An equilateral triangle has all its sides equal, as ABC, fig. 4.

19. An isosceles triangle has two equal sides, as DEF, fig. 5.

20. A scalene triangle has all its sides unequal, as GHI, fig. 6.

Triangles are also denominated according to the angles they contain.

21. A right angled triangle is one that has in it a right-angle, as ABC, fig. 7.

22. A triangle cannot have more than one right angle. The side opposite the right angle B, as AC, is called the hypothenuse, and is always the longest side.

23. An obtuse-angled triangle has one obtuse angle, as fig. 8.

24. An acute-angled triangle has all its angles acute, as fig. 4.

25. An isosceles, or a scalene triangle, may be either right angled, obtuse, or acute.

26. Any side of a triangle is said to subtend the angle opposite to it: thus AB (fig. 7) subtends the angle ACB.

27. If the side of a triangle be drawn out beyond the figure AD (fig. 8), the angle A, or CAB, is called an internal angle, and the angle CAD, or that without the figure, an external angle.

28. A quadrangle is also called a quadrilateral figure. They are of various denominations, as their sides are equal or unequal, or as all their angles are right-angles or not.

29. Every four-sided figure whose opposite sides are parallel, is called a parallelogram. Provided that the sides opposite to each other be parallel, it is immaterial whether the angles are right or not. Figs. 9, 10, 11, and 12, are all parallelograms.

30. When the angles of a parallelogram are all right angles, it is called a rectangular parallelogram, or a rectangle, as figs. 11 and 12.

31. A rectangle may have all its sides equal, or only the opposite sides equal. When all its sides are equal, it is called a square, as fig. 12.

32. When the opposite sides are parallel, and all the sides equal to each other, but the angles not right angles, the parallelogram is called a rhombus, as fig. 10.

33. A parallelogram having all its angles oblique, and only its opposite equal, is called a rhomboid, as fig. 9.

34. When a quadrilateral, or four-sided figure, has none of its sides parallel, it is called a trapezium, as fig. 13; consequently every quadrangle, or quadrilateral, which is not a parallelogram, is a trapezium.

35. A trapezoid has only one pair of its sides parallel, as fig. 14.

36. A diagonal is a right line drawn between any two angles that are opposite in a polygon, as IK, fig. 15. In parallelograms the diagonal is sometimes called the diameter, because it passes through the centre of the figure.

37. Complements of a parallelogram. If any point, as E (fig. 15), be taken in the diagonal of a parallelogram, and through that point two lines are drawn parallel to the sides, as AB, CD, it will be divided into four parallelograms, D, D, L, F, G, G. The two divisions, L, F, through which the diameter does not pass, are called the complements.

38. Base of a figure, is the side on which it is supposed to stand erect, as AD and CD, fig. 16.

39. Altitude of a figure is its perpendicular height from the base to the highest part, as EF, fig. 16.

40. Area of a plane figure, or other surface, means the quantity of space contained within its boundaries, expressed in square feet, yards, or any other superficial measure.

41. Similar figures are such as have the same angles, and whose sides are in the same proportion, as fig. 17.

42. Equal figures are such as have the same area or contents.

43. A circle is a plane figure, bounded by a curve line returning into itself, called its circumference, ABCD (fig. 18), every where equally distant from a point E within the circle, which is called the centre.

44. The radius of a circle is a straight line drawn from the centre to the circumference, as EF (fig. 18). The radius is the opening of the compass when a circle is described; and consequently all the radii of a circle must be equal to each other.

45. A diameter of a circle is a straight line drawn from one side of the circumference to the other through the centre, as CB (fig. 18). Every diameter divides the circle into two equal parts.

46. A segment of a circle is a part of a circle cut off by a straight line drawn across it. The straight line is called the chord. A segment may be either equal to, greater, or less than, a semicircle, which is a segment formed by the diameter of the circle, as CEB, and is equal to half the circle.

47. A tangent is a straight line drawn so as just to touch a circle without cutting it, as GH (fig. 18). The point A, where it touches the circle, is called the point of contact. And a tangent cannot touch a circle in more points than one.

48. A sector of a circle is a space comprehended between two radii and an arc, as IK, fig. 19.

49. The circumference of every circle, whether great or small, is supposed to be divided into 360 equal parts, called degrees; and every degree into 60 parts, called minutes; and every minute into 60 seconds. To measure the inclination of lines to each other, or angles, a circle is described round the angular point as a centre, as IK, fig. 19; and according to the number of degrees, minutes, and seconds, cut off by the sides of the angle, so many degrees, minutes, and seconds, it is said to contain. Degrees are marked by °, and minutes by ′, and seconds by ″; thus an angle of 48 degrees, 15 minutes, and 7 seconds, is written in this manner, 48° 15′ 7″.

50. A solid is any body that has length, breadth, and thickness: a book, for instance, is solid, so is a sheet of paper; for though its thickness is very small, yet it has some thickness. The boundaries of a solid are surfaces.

51. Similar solids are such as are bounded by an equal number of similar planes.

52. A prism is a solid, of which the sides are parallelograms, and the two ends or bases are similar polygons, parallel to each other. Prisms are denominated according to the number of angles in the base, triangular prisms, quadrangular, heptangular, and so on, as figs. 20, 21, 22, 23. If the sides are perpendicular to the plane of the base, it is called an upright prism; if they are inclined, it is called an oblique prism.

53. When the base of a prism is a parallelogram, it is called a parallelopipedon, as figs. 22 and 23. Hence a parallelopipedon is a solid terminated by six parallelograms.

54. When all the sides of a parallelopipedon are squares, the solid is called a cube, as fig. 23.

55. A rhomboid is an oblique prism, whose bases are parallelograms (fig. 24).

56. A pyramid (figs. 25 and 26) is a solid bounded by, or contained within, a number of planes, whose base may be any polygon, and whose faces are terminated in one point, B, commonly called the vertex of the pyramid.

57. When the figure of the base is a triangle, it is called a triangular pyramid; when the figure of the base is a quadrilateral, it is called a quadrilateral pyramid, &c.

58. A pyramid is either regular or irregular, according as the base is regular or irregular.

59. A pyramid is also right or upright, or it is oblique. It is right, when a line drawn from the vertex to the centre of the base, is perpendicular to it, as fig. 25; and oblique, when this line inclines, as fig. 26.

60. A cylinder is a solid (figs. 27 and 28), generated or formed by the rotation of a rectangle about one of its sides, supposed to be at rest: this quiescent side is called the axis of the cylinder. Or it may be conceived to be generated by the motion of a circle, in a direction perpendicular to its surface, and always parallel to itself.

61. A cylinder is either right or oblique, as the axis is perpendicular to the base or inclined.

62. Every section of a right cylinder taken at right angles to its axis, is a circle; and every section taken across the cylinder, but oblique to the axis, is an ellipsis.

63. A circle being a polygon of an infinite number of sides, it follows, that the cylinder may be conceived as a prism, having such a polygon for bases.

64. A cone is a solid (figs. 29 and 30), having a circle for its base, and its sides a convex surface, terminating in a point A, called the vertex, or apex of the cone. It may be conceived to be generated by the revolution of a right-angled triangle about its perpendicular.

65. A line drawn from the vertex to the centre of the base is the axis of the cone.

66. When this line is perpendicular to the base, the cone is called an upright, or right cone; but when it is inclined it is called an oblique cone.

67. If it be cut through the axis from the vertex to the base, the section will be a triangle.

68. If a right cone be cut by a plane at right angles to the axis, the section will be a circle.

69. If it be cut oblique to the axis, and quite across from one side to the other, the section will be an ellipsis, as fig. 31. A section of a cylinder made in the same manner is also an ellipsis; and that is easily conceived: but it does not appear so readily to most people, that the oblique section of a cone is an ellipsis: they frequently imagine that it will be wider at one end than the other, or what is called an oval, which is the shape of an egg. But that this is a mistake, any one may convince himself by making a cone, and cutting it across obliquely; it will be then seen that the section, in whatever direction it is taken, is a regular ellipsis; and this is the case, whether the cone be right or oblique, except only in one case in the oblique cone; which is when the section is taken in a particular direction, which is called sub-contrary to its base.

70. When the section is made parallel to one of the sides of the cone, as fig. 32, the curve ABC, which bounds the section, is called a parabola.

71. When the section is taken parallel to the axis, as fig. 33, the curve is called a hyperbola.

These curves, which are formed by cutting a cone in

different directions, have various properties, which are of great importance in astronomy, gunnery, perspective, and many other sciences.

72. A sphere is a solid, terminated by a convex surface, every point of which is at an equal distance from a point within, called the centre, fig. 34.

73. It may be conceived to be formed by making a semicircle revolve round its diameter. This may be illustrated by the process of forming a ball of clay by the potter's wheel, a semicircular mould being used for the purpose. The diameter of the semicircle round which it revolves, is called the axis of the sphere.

74. The ends of the axis are called poles.

75. Any line passing through the centre of the sphere, and terminated by the circumference, is a diameter of the sphere.

76. Every section of a sphere is a circle; every section taken through the centre of the sphere is called a great circle, as AB, fig. 34; every other is a lesser circle, as CD.

77. Any portion of a sphere cut off by a plane is called a segment; and when the plane passes through the centre, it divides the sphere into two equal parts, each of which is called a hemisphere.

78. A spheroid is a solid (fig. 35), generated by the rotation of a semi-ellipsis about the transverse or conjugate axis; and the centre of the ellipsis is the centre of the spheroid.

79. The line about which the ellipsis revolves is called the axis. If the spheroid be generated about the conjugate axis of the semi-ellipsis, it is called a prolate spheroid.

80. If the spheroid be generated by the semi-ellipsis by revolving about the transverse axis, it is called an oblong spheroid.

81. Every section of a spheroid is an ellipsis, except when it is perpendicular to that axis about which it is generated; in which case it is a circle.

82. All sections of a spheroid parallel to each other, are similar figures.

A frustum of a solid, means a piece cut off from the solid by a plane passed through it, usually parallel to the base of the solid, as the frustum of a cone, a pyramid, &c.

There are a lower and an upper frustum, according as the piece spoken of does or does not contain the base of the solid.

83. Ratio is the proportion which one magnitude bears to another of the same kind, with respect to quantity, and is usually marked thus, A : B.

Of these the first is called the antecedent, and the second the consequent.

84. The measure or quantity of a ratio is conceived by considering what part of the consequent is the antecedent; consequently it is obtained by dividing the consequent by the antecedent.

85. Three magnitudes or quantities, A, B, C, are said to be proportional, when the ratio of the first to the second is the same as that of the second to the third. Thus 2, 4, 8, are proportional; because 4 is contained in 8 as many times as 2 is in 4.

86. Four quantities, A, B, C, D, are said to be proportional when the ratio of the first A to the second B is the same as the ratio of the third C to the fourth D. It is usually written A : B : : C : D, or, if expressed in numbers, 2 : 4 : : 8 : 16.

87. Of three proportional quantities, the middle one is said to be a mean proportional between the other two; and the last a third proportional to the first and second.

88. Of four proportional quantities, the last is said to be a fourth proportional to the other three, taken in order.

89. Ratio of equality is that which equal numbers bear to each other.

90. Inverse ratio is when the antecedent is made the consequent, and the consequent the antecedent. Thus, if 1 : 2 :: 3 : 6; then inversely, 2 : 1 :: 6 : 3.

91. Alternate proportion is when antecedent is compared with antecedent, and consequent with consequent. Thus, if 2 : 1 :: 6 : 3; then by alteration 2 : 6 :: 1 : 3.

92. Proportion by composition is when the antecedent and consequent, taken as one quantity, are compared either with the consequent or with the antecedent. Thus, if 2 : 1 :: 6 : 3; then by composition 2 + 1 : 1 :: 6 + 3 : 3: and 2 + 1 : 2 : 6 + 3 : 6.

93. Divided proportion is when the difference of the antecedent and consequent is compared either with the consequent or with the antecedent. Thus, if 3 : 1 :: 12 : 4; then, by division, 3 — 1 : 1 :: 12 — 4 : 4, and 3 — 1 : 3 :: 12 — 4 : 12.

94. Continued proportion is when the first is to the second as the second is to the third; as the third to the fourth; as the fourth to the fifth; and so on.

95. Compound ratio is formed by the multiplication of several antecedents and the several consequents of ratios together, in the following manner:

If A be to B as 3 to 5, B to C as 5 to 8, and C to D as 8 to 6; then A will be D, as $\frac{3 \times 5 \times 8}{5 \times 8 \times 6} = \frac{120}{240} = \frac{1}{2}$; that is, A : D :: 1 : 2.

96. *Bisect* means to divide any thing into two equal parts.

97. *Trisect* is to divide any thing into three equal parts.

98. *Inscribe*, to draw one figure within another, so that all angles of the inner figure touch either the angles, sides, or planes, of the external figure.

99. *Circumscribe*, to draw a figure round another, so that either the angles, sides, or planes of the circumscribed figure, touch all the angles of the figure within it.

100. Rectangle under any two lines, means a rectangle which has two of its sides equal to one of the lines, and two of them equal to the other. Also the rectangle under AB, CD, means AB × CD.

101. Scales of equal parts. A scale of equal parts is only a straight line, divided into any number of equal parts at pleasure. Each part may represent any measure you please, as an inch, a foot, a yard, &c. One of these is generally subdivided into parts of the next denomination, or into tenths and hundredths. Scales may be constructed in a variety of ways. The most usual manner is to make an inch, or some aliquot part of an inch, to represent a foot; and then they are called inch scales, three-quarter-inch scales, half-inch scales, quarter-inch scales, &c. They are usually drawn upon ivory or boxwood. See Instruments.

102. An axiom is a manifest truth, not requiring any demonstration.

103. Postulates are things required to be granted true, before we proceed to demonstrate a proposition.

104. A proposition is when something is either proposed to be done, or to be demonstrated; and is either a problem or a theorem.

105. A problem is when something is proposed to be done, as some figure to be drawn.

106. A theorem is when something is proposed to be demonstrated or proved.

107. A lemma is when a premise is demonstrated, in order to render the thing in hand more easy.

108. A corollary is an inference drawn from the demonstration of some proposition.

109. A scholium is when some remark or observation is made upon something mentioned before.

110. The sign = denotes that the quantities betwixt which it stands are equal.

111. The sign + denotes that the quantity after it, is to be added to that immediately before it.

112. The sign — denotes that the quantity after it is to be taken away, or subtracted from, the quantity preceding it.

Geometrical Problems.

Prob. 1. To divide a given line AB into two equal parts.

From the points A and B as centres, and with any opening of the compasses greater than half AB, describe arches, cutting each other in c and d. Draw the line c d; and the point E, where it cuts AB, will be the middle required.

Prob. 2. To raise a perpendicular to a given line AB, from a point given at C.

Case 1. When the given point is near the middle of the line on each side of the point C. Take any two equal distances, C d and C e; from d, and e, with any radius or opening of the compasses greater than C d, or C e, describe two arcs cutting each other in f. Lastly, through the points f, C, draw the line f C, and it will be the perpendicular required.

Case 2. When the point is at, or near, the end of the line. Take any point d, above the line, and with the radius or distance d C, describe the arc e C f, cutting AB in e and C. Through the centre d, and the point e, draw the line e d f, cutting the arc e C f in f. Through the points f, C, draw the line f C, and it will be the perpendicular required.

Prob. 3. From a given point f, to let fall a perpendicular upon a given line AB.

From the point f, with any radius, describe the arc d e, cutting AB in e and d. From the points e d, with the same or any other radius, describe the two arcs, cutting each other in g. Through the points f and g, draw the line f g, and f C will be the perpendicular required.

Prob. 4. To make an angle equal to another angle which is given, as a B b.

From the point B, with any radius, describe the arc a b, cutting the legs B a, B b, in the points a and b. Draw the line D e, and from the point D, with the same radius as before, describe the arc e f, cutting D e in e. Take the distance b a, and apply it to the arc e f, from e to f. Lastly, through the points D, f, draw the line D f, and the angle e D f will be equal to the angle b B a, as was required.

Prob. 5. To divide a given angle, ABC, into two equal angles.

From the point B, with any radius, describe the arc AC. From A and C with the same, or any other radius, describe arcs cutting each in d. Draw the line B d, and it will bisect the angle ABC, as was required.

Prob. 6. To lay down an angle of any number of degrees.

There are various methods of doing this. One is by the use of an instrument called a protractor, with a semicircle of brass, having its circumference divided into degrees. Let AB be a given line, and let it be required to draw from the angular point A, a line making with AB any number of degrees, suppose 20. Lay the straight side of the protractor along the line AB, and count 20° from the end B of the semicircle; at C, which is 20° from B, mark; then, removing the protractor, draw the line AC, which makes with AB the angle required. Or, it may be done by a divided line, usually drawn upon scales, called a line of chords. Take 60° from the line of chords in the compasses, and setting one at the angular point B, prob. 4, with that opening as a radius, describe an arch, as a b: then take the number of degrees you intend the angle to be of, and set it from b to a, then is a B b the angle required. See Instruments.

Prob. 7. Through a given point C, to draw a line parallel to a given line AB.

Case 1. Take any point d, in AB; upon d and C, with the distance C d, describe two arcs, e C, and d f, cutting the line AB in e and d. Make d f equal to e C; through C and f draw C f, and it will be the line required.

Case 2. When the parallel is to be at a given distance from AB. From any two points, c and d, in the line AB, with a radius equal to the given distance, describe the arcs e and f: draw the line CB to touch those arcs without cutting them, and it will be parallel to AB, as was required.

Prob. 8. To divide a given line AB, into any proposed number of equal parts.

From A, one end of the line, draw A c, making any angle with AB; and from B, the other end, draw B d, making the angle ABd equal to BAc. In each of these lines, A c, B d, beginning at A and B, set off as many equal parts of any length as AB is to be divided into. Join the points C 5, 46, 57, and AB will be divided as required.

Prob. 9. To find the centre of a given circle, or of any one already described. Draw any chord, AB, and bisect it with the perpendicular CD. Bisect CD with the diameter EF, and the intersection O will be the centre required.

Prob. 10. To draw a tangent to a given circle that shall pass through a given point, A.

From the centre O, draw the radius OA. Through the point A, draw DE perpendicular to OA, and it will be the tangent required.

Prob. 11. To draw a tangent to a circle, or any segment of a circle ABC, through a given point B, without making use of the centre of the circle.

Take any two equal divisions upon the circle from the

given point B, towards d and e, and draw the chord e B. Upon B, as a centre, with the distance B d, describe the arc f d g. cutting the chord e B in f. Make d g equal to d f; through g draw g B, and it will be the tangent required.

Prob. 12. Given three points, A, B, C, not in a straight line, to describe a circle that shall pass through them.

Bisect the lines AB, BC, by the perpendiculars a d, b d, meeting at d. Upon d, with the distance d A, d B, describe ABC, and it will be the required circle.

Prob. 13. To describe the segment of a circle to any length AB, and height CD.

Bisect AB by the perpendicular D g, cutting AB in c. From c make c D on the perpendicular equal to CD. Draw AD, and bisect it by a perpendicular e f, cutting D g in g. Upon g the centre, describe ADB, and it will be the required segment.

Prob. 14. In any given triangle to inscribe a circle.

Bisect any two angles, A and C, with the lines AD and DC. From D the point of intersection, let fall the perpendicular DE; it will be the radius of the circle required.

Prob. 15. In a given square, to describe a regular octagon.

Draw the diagonals AC and BD, intersecting at e. Upon the points A, B, C, D, as centres, with a radius e C, describe the arcs k e n, m e g, f e i, &c. Join f n, m b, k i, l g, and it will be the required octagon.

Prob. 16. In a given circle, to describe any regular polygon.

Divide the circumference into as many parts as there are sides in the polygon to be drawn, and join the points of division.

Prob. 17. Upon a given line AB, to construct an equilateral triangle.

Upon the points A, and B, with a radius equal to AB, describe arches cutting each other at C. Draw AC and BC, and ABC will be the triangle required.

Prob. 18. To make a trapezium equal and similar to a given trapezium ABCD.

Divide the given trapezium ABCD into two triangles by the diagonal DB. Make EF equal to AB; upon EF construct the triangle EFH, whose sides shall be respectively equal to those of the triangle ABD by the last problem. Upon HF, which is equal to DB, construct the triangle HFG, whose sides are respectively equal to DBC; then EFGH will be the trapezium required.

By the help of this problem any plan may be copied; as every figure, how ever irregular, may be divided into triangles. Upon this the practice of land-surveying and making plans of estates, is founded.

Prob. 19. To make a square equal to two given squares. Make the sides DE and DF of the two given squares A and B, form the sides of a right-angled triangle FDE; draw the hypothenuse FE; on it describe the square EFGH, and it will be the square required.

Prob. 20. Between two given lines, AB and CD, to find a mean proportional.

Draw the right line EG, in which make EF equal to AB, and FG equal to CD. Bisect EG in H, and with HE or HG, as radius, describe the semicircle EIG. From F draw FI perpendicular to EG, cutting the circle in I; and IF will be the mean proportional required.

GEOMETRY, *application of algebra to.* When a geometrical problem is proposed to be resolved by algebra, you are, in the first place, to describe a figure that shall represent, or exhibit, the several parts or conditions thereof, and look upon that figure as the true one; then, having considered attentively the nature of the problem you are next to prepare the figure for a solution (if need be), by producing and drawing such lines therein as appear most conducive to that end. This done, let the unknown line or lines which you think will be the easiest found (whether required or not), together with the known ones (or as many of them as are requisite), be denoted by proper symbols; then proceed to the operation, by observing the relation that the several parts of the figure have to each other; in order to which a competent knowledge of the elements of geometry is absolutely necessary.

As no general rule can be given for the drawing of lines, and electing the most proper quantities to substitute for, so as to always bring out the most simple conclusions (because different problems require different methods of solution); the best way, therefore, to gain experience in this matter, is to attempt the solution of the same problem several ways, and then apply that which succeeds best to other cases of the same kind when they afterwards occur. We shall, however, subjoin a few general directions, which will be found of use.

1. In preparing the figure, by drawing lines, let them be either parallel or perpendicular to other lines in the figure, or so as to form similar triangles; and, if an angle be given, let the perpendicular be opposite to that angle, and also fall from the end of a given line, if possible.

2. In electing the proper quantities to substitute for, let those be chosen (whether required or not) which lie nearest the known, or given parts of the figure, and by help whereof the next adjacent parts may be expressed, without the intervention of surds, by addition and subtraction only. Thus, if the problem were to find the perpendicular of a plane triangle, from the three sides given, it will be much better to substitute for one of the segments of the base than for the perpendicular, though the quantity required; because the whole base being given, or expressed, by subtraction only, and so the final equation comes out a single one; from whence the segments being known, the perpendicular is easily found by common arithmetic: whereas, if the perpendicular were to be first sought, both the segments would be surd quantities, and the final equation an unsightly quadratic one.

3. When, in any problem, there are two lines or quantities alike related to other parts of the figure, or problem, the best way is to make use of neither of them, but to substitute for their sum, their rectangle, or the sum of their alternate quotients, or for some line or lines in the figure, to which they have both the same relation.

4. If the area, or the perimeter, of a figure be given, or such parts thereof as have but a remote relation to the parts required, it will sometimes be of use to assume another figure similar to the proposed one, whereof one side is unity, or some other known quantity; from whence the other parts of this figure, by the known proportions of the homologous sides, or parts, may be found, and an equation obtained.

These are the most general observations, which we shall now proceed to illustrate by examples.

Prob. I. *The base* (b), *and the sum of the hypothenuse and perpendicular* (a) *of a right-angled triangle* ABC, *being given; to find the perpendicular.* See Fig. 36.

Let the perpendicular BC be denoted by x; then the hypothenuse AC will be expressed by $a - x$; but (by Euc. 47. 1.) $AB^2 + BC^2 = AC$; that is, $b^2 + x^2 = a^2 - 2ax + xx$; whence $x = \frac{a^2 - b^2}{2a} =$ the perpendicular required.

Prob. II. *The diagonal, and the perimeter of a rectangle,* ABCD, *being given; to find the sides.* See Fig. 37.

Put the diagonal $BD = a$, half the perimeter $(DA + AB) = b$, and $AB = x$; then will $AD = b - x$; and therefore, $AB^2 + AD^2$ being $= BD^2$, we have $x^2 + b^2 - 2bx + x^2 = b^2$; which, solved, gives $x = \frac{\sqrt{2a^2 - b^2} + b}{2}$.

Prob. III. *The area of a right-angled triangle* ABC, *and the sides of a rectangle* EBDF, *inscribed therein, being given; to determine the sides of the triangle.* See Fig. 38.

Put $DF = a$, $DE = b$, $BC = x$, and the measure of the given area $ABC = d$; then, by similar triangles, we shall have $x - b$ (CF) : a (DF) : : x (BC) : $AB = \frac{ax}{x-b}$. Therefore $\frac{ax}{a-b} \times \frac{x}{2} = d$, and consequently $ax^2 = 2dx - 2bd$, or $x^2 - \frac{2dx}{a} = -\frac{2bd}{a}$; which, solved, gives $x = \frac{d}{a} \pm \sqrt{\frac{dd}{aa} - \frac{2bd}{a}}$; from whence AB and AC will likewise be known.

Prob. IV. *Having the lengths of the three perpendiculars,* PF, PG, PH, *drawn from a certain point* P, *within an equilateral triangle* ABC, *to the three sides thereof; from thence to determine the sides.* See Fig. 39.

Let lines be drawn from P to the three angles of the triangle; and let CD be perpendicular to AB: call PF, a; PG, b; PH, c; and $AD = x$: then will AC $(= AB) = 2x$, and $CD (= \sqrt{AC^2 - AD^2}) = \sqrt{3xx} = x\sqrt{3}$; and consequently the area of the whole triangle ABC $(= CD \times AD) = xx\sqrt{3}$. But this triangle is composed of the three triangles APB, BPC, and APC; whereof the respective areas are ax, bx, and cx. Therefore we have $xx\sqrt{3} = ax + bx + cx$; and from thence, by division, $x = \frac{a+b+c}{\sqrt{3}}$.

Prob. V. *Having the area of a rectangle* DEFG, *inscribed in a given triangle* ABC; *to determine the sides of the rectangle.* See Fig. 40.

Let CI be perpendicular to AB, cutting DG in H; and let $CI = a$, $AB = b$, $DG = x$, and the given area $= cc$; then it will be, as $b : x : : a : \frac{ax}{b} = CH$; which, taken from CI, leaves $a - \frac{ax}{b} = IH$; and this, multiplied by x, gives $ax - \frac{ax^2}{b} = cc =$ the area of the rectangle; whence we have $abx - ax^2 = bcc$, $x^2 - bx = -\frac{bcc}{a}$, $x - \frac{b}{2} = \pm\sqrt{\frac{b^2}{4} - \frac{bcc}{a}}$, and $x = \frac{b}{2} \pm \sqrt{\frac{b^2}{4} - \frac{bcc}{a}}$.

Prob. VI. *Through a given point* P, *within a given circle, so to draw a right line, that the two parts thereof,* PR, PQ, *intercepted by that point and the circumference of the circle, may have a given difference.* See Fig. 41.

Let the diameter PBA be drawn; and let AP and BP, the two parts thereof (which are supposed given) be denoted by a and b; making $PR = x$, and $PQ = x + d$ (d being the given difference). Then, by the nature of the circle, $PQ \times PR$ being $= PA \times PB$, we have $\overline{x + d} \times x = ab$, or $xx + dx = ab$; whence x is found $= \sqrt{ab + \frac{1}{4}dd} - \frac{1}{2}d$.

Prob. VII. *From a given point* P, *without a given circle, so to draw a right line* PQ, *that the part thereof* RQ, *intercepted by the circle, shall be to the external part* PR, *in a given ratio.* See Fig. 42.

Through the centre O, draw PAB; put $PA = a$, $PB = b$, $PR = x$, and let the given ratio of PR to RQ be that of m to n; then it will be, as $m : n : : x : n\frac{nx}{m} = RQ$; therefore $PQ = x + \frac{nx}{m}$: but $PR \times PQ = PA \times PB$, or $x \times \overline{x + \frac{nx}{m}} = ab$; therefore $mx^2 + nx^2 = mab$, and $x = \sqrt{\frac{b}{m+n}}$.

Prob. VIII. *The sum of the two sides of an isosceles triangle* ABC, *being equal to the sum of the base and perpendicular, and the area of the triangle being given; to determine the sides.* See Fig. 43.

Put the semi-base $AD = x$, the perpendicular $CD = y$, and the given area $ABC = a^2$; so shall $xy = a^2$, and $2\sqrt{xx + yy} = 2x + y$ (by El. 47. 1. and the conditions of the problem). Now, squaring both sides of the last equation, we have $4xx + 4yy = 4xx + 4xy + yy$; whence $3yy = 4xy$, and consequently $y = \frac{4x}{3}$; which value, substituted in the former equation, gives $\frac{4xx}{3} = a^2$; from whence $x = \sqrt{\frac{3a^2}{4}} = \frac{1}{2}a\sqrt{3}$; $y \left(= \frac{4x}{3}\right) = \frac{2}{3}a\sqrt{3}$; and AC $(= \sqrt{xx + yy} = \sqrt{\frac{3aa}{4} + \frac{4aa}{3}} = \sqrt{\frac{2\ aa}{12}}) = \frac{5}{2}a\sqrt{\frac{1}{3}} = \frac{5}{6}a\sqrt{3}$.

Prob. IX. *The segments of the base* AD *and* BD, *and the ratio of the sides* AC *and* BC *of any plane triangle* ABC, *being given; to find the sides.* See Fig. 44.

Put $AD = a$, $BD = b$, $AC = x$; and let the given ratio of AC to BC, be as m to n, so shall $BC = \frac{nx}{m}$. But $AC^2 - AD^2 (= DC^2) = BC^2 - BD^2$, that is, in species, $x^2 - a^2 = \frac{nnxx}{mm} - b^2$. Hence we have $m^2x^2 - n^2x^2 = m^2 \times aa - bb$, and $x = m\sqrt{\frac{aa - bb}{mm - nn}}$.

Geometry, *usefulness of*. The usefulness of this science extends to almost every art and science. It is by the help of it that astronomers turn their observations to advantage, regulate the duration of times, seasons, years, cycles, and epochs; and measure the distance, motions, and magnitudes, of the heavenly bodies It is by it that geographers determine the figure and magnitude of the whole earth, and delineate the extent and bearings of kingdoms. provinces, harbours, &c. It is from this science too that architects derive their just measures, in the construction of public edifices as well as of private houses. It is by the assistance of geometry that engineers conduct all their works, take the situation and plans of towns, the distances of places, and the measure of such things as are only accessible to the sight. It is not only an introduction to fortification, but highly necessary to most mechanics, especially carpenters, joiners, mathematical-instrument makers, and all who profess designing. On geometry likewise depends the theory of music, optics, perspective, drawing, mechanics, hydraulics, pneumatics, &c.

GEORGE, or *knights of St. George*. See Garter.

Religious of the order of St. George, form several congregations in Italy and other places.

GEORGIC, a poetical composition upon the subject of husbandry. See Poetry.

GERANIUM, *crane's-bill*, a genus of the decandria order, in the monadelphia class of plants, and in the natural method ranking under the 14th order, gruinales. Its characters are these: the flower has a permanent empalement, composed of five small oval leaves, and five oval or heart-shaped petals, spreading open, which are in some species equal, and in others the upper two are much larger than the three lower. It has ten stamina, alternately longer than each other, but shorter than the petals, and terminated by oblong summits. In the bottom of the flower is situated a five-cornered germen, which is permanent. The flower is succeeded by five seeds, each being wrapped up in the husk of the beak, where they are twisted together at the point, so as to form the resemblance of a stork's beak. There are 32 species.

The common wild sorts of this plant, and those also which are brought to the curious from the colder climates, are hardy enough, and require little care; but the southern species require care in their culture and propagation, and in general the protection of a greenhouse in the winter. The erodium, and the pelargorium, or African geranium, are vulgarly called by the name of geraniums, and indeed resemble this genus in every thing but the number of the stamina. The eradium has five stamina, and the pelargoriam seven.

GERARDIA, in botany, a genus of the didynamia angiospermia class of plants, the corolla of which consists of a single ringent petal; the tube is roundish, and longer than the cup; the upper lip is erect, obtuse, plain, and emarginated; the lower lip is reflected, and divided into three segments: the fruit is an oval capsule, containing two cells, and consisting of two valves; the seeds are oval and single. There are ten species, herbaceous plants of America and the Cape. One species is much recommended in gouty disorders.

GERMEN. See Botany.

GERMINATION, in botany. Natural historians have proved, by a very complete induction of facts, that all plants arise from seeds. The pretended exceptions have disappeared, one after another, as our knowledge of vegetables increased; and now there remains scarcely a single objection entitled to the smallest regard. The late attempt of Girtanner to revive the doctrine of equivocal generation deserves no attention whatever; because his conclusions are absolutely incompatible with the experiments of Mr. Sennebier upon the very substance on which his theory is founded.

A seed consists of three parts, namely, the cotyledons, the radicle, and the plumula, which are usually inclosed in a cover.

If we take a garden-bean, we may perceive each of these three parts with great ease; for this seed is of so large a size, that all its organs are exceedingly distinct. When we strip off the external coats of the bean, which are two, and of different degrees of thickness in different parts, we find that it easily divides into two lobes, pretty nearly of the same size and figure. Each of these lobes is called a cotyledon. The cotyledons of the bean, then, are two in number.

Near that part of the lobes which is contiguous to what is called the eye of the bean, there is a small round white body, which comes out between the two lobes. This body is called the radicle.

Attached to the radicle there is another small round body, which lies between the cotyledons, and wholly within them; so that it cannot be seen till they are separated from each other. The body is called the plumula.

The appearance and shape of these three parts differ very much in different seeds, but there is no seed which wants them. The figure and size of the seed depend chiefly upon the cotyledons. This is evidently the case with the bean, and it is so with all other seeds. The number of cotyledons is different in different seeds. Some seeds have only one cotyledon, as the seeds of wheat, oats, barley, and the whole tribe of grasses; some have three; others six, as the seeds of the garden-cress; but most seeds, like the bean, have two cotyledons.

When a seed is placed in a situation favourable to vegetation, it very soon changes its appearance. The radicle is converted into a root, and sinks into the earth; the plumula, on the other band, rises above the earth, and becomes the trunk or stem. When these changes take place the seed is said to germinate: the process itself has been called germination. Seeds do not germinate equally and indifferently in all places and seasons. Germination, therefore, is a process which does not depend upon the seed alone: something external must also effect it.

It is a well-kown fact, that seeds will not germinate without moisture; for seeds, if they are kept perfectly dry, never vegetate at all, and yet their power of vegetating is not destroyed. Water, then, is essential to germination. Too much water, however, is no less prejudicial to most seeds than none at all. The seeds of water-plants, indeed, germinate and vegetate extremely well in water; but most other seeds, if they are kept in water beyond a certain time, are rotted and destroyed altogether.

It is well known also, that seeds will not germinate,

even though supplied with water, provided the temperature is below a certain degree. No seed, for instance, on which the experiment has been tried, can be made to vegetate at or below the freezing-point: yet this degree of cold does not injure the vegetating power of seeds; for any seeds will vegetate as well as ever after having been frozen, or after having been kept in frozen water. We may conclude, then, that a certain degree of heat is necessary for the germination of seeds. And every species of plant seems to have a degree peculiar to itself, at which its seeds begin to germinate; for every seed has a peculiar season at which it begins to germinate, and this season varies with the temperature of the air. Mr. Adanson found that seeds, when sown at the same time in France and in Senegal, always appeared sooner above ground in the latter country, where the climate is hotter, than in France.

Seeds, although supplied with moisture, and placed in a proper temperature, will not germinate, if atmospherical air is completely excluded from them. Mr. Ray found that grains of lettuce did not germinate in the vacuum of an air-pump, but they began to grow as soon as air was admitted to them. Homberg made a number of experiments on the same subject, which were published in the Memoirs of the French Academy for the year 1693. He found that the greater number of seeds which he tried refused to vegetate in the vacuum of an air-pump. Some, however, did germinate; but Boyle, Muschenbroek, and Boerhaave, who made experiments on the same subject in succession, proved beyond a doubt that no plant vegetates in the vacuum of an air-pump; and that in those cases in which Homberg's seeds germinated, the vacuum was far from perfect, a quantity of air still remaining in the receiver. It follows, therefore, that no seed will germinate unless atmospherical air, or some air having the same properties, has access to it. It is for this reason that seeds will not germinate at a certain depth below the surface of the earth.

Mr. Scheele found that beans would not germinate except oxygen gas was present. Mr. Achard afterwards proved that oxygen gas is absolutely necessary for the germination of all seeds, and that no seed will germinate in azotic gas, or hydrogen gas, or carbonic acid gas, unless these gasses contain a mixture of oxygen gas. These experiments have been confirmed by Mr. Gough, Mr. Cruckshank, and many other philosophers. It follows, therefore, that it is not the whole atmospheric air, but merely the oxygen gas which it contains, that is necessary for the germination of seeds.

Nay, M. Humboldt has ascertained that seeds vegetate more rapidly when steeped in oxymuriatic acid, or when watered with it; and this acid is well known for the facility with which it parts with oxygen. This acid seems even to augment the vegetative power of seeds. At Vienna several seeds which had been long kept, and which had constantly refused to germinate, grew readily when treated with this acid.

Light also has considerable influence in the germination of seeds. Ingenhousz found that seeds always germinate faster in the dark than when exposed to the light. His experiments were repeated by Mr. Sennebier with equal success. But the abbe' Bertholin, who distinguished himself so much by his labours to demonstrate the effect of electricity on vegetation, objected to the conclusions of these philosophers; and affirmed that the difference in the germination of seeds in the shade and in the light was owing, not to the light itself, but to the difference of the moisture in the two situations; the moisture evaporating much faster from the seeds in the light than from those in the shade; and he affirmed, that when precautions were taken to keep the seeds equally moist, those in the sun germinated sooner than those in the shade. But when Mr. Sennebier repeated his former experiments, and employed every possible precaution to ensure the equality of moisture in both situations, he constantly found the seeds in the shade germinate sooner than those in the light. We may conclude, therefore, that light is injurious to germination; and hence one reason for covering seeds with the soil in which they are to grow.

Thus we have seen that seeds will not germinate unless moisture, heat, and oxygen gas, are present; and that they do not germinate well if they are exposed to the action of light. Now, in what manner do these substances affect the seed? What are the changes which they produce?

It was observed before, that all seeds have one or more cotyledons. These cotyledons contain a quantity of farinaceous matter, laid up on purpose to supply the embryo plant with food as it begins to require it. This food, however, must undergo some previous preparation before it can be applied by the plant to the formation or completion of its organs. Now all the phenomena of germination, which we can perceive, consists in the chemical changes which are produced in that food, and the consequent developement of the organs of the plant.

When a seed is placed in favourable circumstances, it gradually imbibes moisture, and very soon after emits a quantity of carbonic acid gas, even though no oxygen gas should be present. If no oxygen gas is present, the process stops here, and no germination takes place. But if oxygen gas is present, it is gradually absorbed by the seed; and at the same time the farina of the cotyledons assume a sweet taste, resembling sugar: it is therefore converted into sugar, or some substance analogous to it. M. Saussure, jun. has ascertained that the quantity of oxygen gas absorbed during the germination is always proportional to the carbonic acid gas emitted; that is, the carbonic acid emitted contains in it precisely the same quantity of oxygen as has been absorbed. Hence it is evident that the farina is changed into sugar by diminishing its carbon, and of course by augmenting the proportion of its hydrogen and oxygen. This is precisely the process of malting, or of converting grain into malt; during which it is well known that there is a considerable heat envolved; so much indeed, that in certain circumstances grain improperly kept has even taken fire. We may conclude from this, that during the germination of seeds in the earth there is also an evolution of a considerable portion of heat. This indeed might have been expected, as it usually happens when oxygen gas is absorbed.

So far seems to be the work of chemistry alone, at least we have no right to conclude that any other agent interferes; since hay, when it happens to imbibe moisture, exhibits nearly the same process. Carbonic acid gas is evolved, oxygen gas is absorbed, heat is produced so

abundantly that hay often takes fire: at the same time a quantity of sugar is formed. It is owing to a partial change of the same kind that old hay generally tastes much sweeter than new hay. Now we have no reason to suppose that any agents peculiar to the vegetable kingdom reside in hay: as all vegetation, and all power of vegetating, are evidently destroyed.

But when the farina in the seeds of vegetables is converted into sugar, a number of vessels make their appearance in the cotyledon. These vessels may indeed be detected in many seeds before germination commences; but they become much more distinct after it has made some progress. Branches from them have been demonstrated by Grew, Malpighi, and Hedwig, passing into the radicle, and distributed through every part of it. These evidently carry the nourishment prepared in the cotyledons to the radicle; for if the cotyledons are cut off, even after the processes above described are completed, germination, as Bonnet and Sennebier ascertained by experiment, immediately stops. The food therefore is conveyed from the cotyledons into the radicle; the radicle increases in size, assumes the form of a root, sinks down into the earth, and soon becomes capable of extracting the nourishment necessary for the future growth of the plant. Even at this period, after the radicle has become a perfect root, the plant, as Sennebier ascertained by experiment, ceases to vegetate if the cotyledons are cut off. They are still then absolutely necessary for the vegetation of the plant.

The cotyledons now assume the appearance of leaves, and appear above the ground, forming what are called the seminal leaves of the plant. After this the plumula gradually increases in size, rises out of the earth, and expands itself into branches and leaves. The seminal leaves, soon after this, decay and drop off; and the plant carries on all the processes of vegetation without their assistance.

Mr. Eller attempted to show that there is a vessel in seeds which passes from the cotyledons to the plumula; but later anatomists have not been able to perceive any such vessel. Even Mr. Hedwig, one of the most patient, acute, and successful philosophers that ever examined the structure of vegetables, could never discover any such vessel, although he traced the vessels of the cotyledons even through the radicle. As it does not appear, then, that there is any communication between the cotyledons and the plumula, it must follow that the nourishment passes into the plumula from the radicle: and accordingly we see that the plumula does not begin to vegetate till the radicle has made some progress. Since the plant ceases to vegetate, even after the radicle has been converted into a root, if the cotyledons are removed before the plumula is developed, it follows that the radicle is insufficient of itself to carry on the processes of vegetation, and that the cotyledons still continue to perform a part. Now we have seen already what that part is; they prepare food for the nourishment of the plant. The root, then, is of itself insufficient for this purpose. When the cotyledons assume the form of seminal leaves, it is evident that the nourishment, which was originally laid up in them for the support of the embryo plant, is exhausted, yet they still continue as necessary as ever. They must therefore receive the nourishment which is imbibed by the root; they must produce some changes on it, render it suitable for the purposes of vegetation, and then send it back again to be transmitted to the plumula.

After the plumula has acquired a certain size, which must be at least a line, if the cotyledons are cut off, the plant, as Mr. Bonnet ascertained by a number of experiments, afterwards repeated with equal success by Mr. Sennebier, does not cease to vegetate, but it continues always a mere pigmy: its size, when compared with that of a plant whose cotyledons are allowed to remain, being only as 2 to 7.

When the plumula has expanded completely into leaves, the cotyledons may be removed without injuring the plant, and they very soon decay of themselves. It appears, then, that this new office of the cotyledons is afterwards performed by that part of the plant which is above ground.

Thus we have traced the phenomena of germination as far as they have been detected. The facts are obvious; but the manner in which they are produced is a profound secret. We can neither explain how the food enters into the vessels, how it is conveyed to the different parts of the plant, how it is deposited in every organ, nor how it is employed to increase the size of the old parts, or to form new ones. These phenomena are analogous to nothing in mechanics or chemistry, but resemble exactly the organization and nourishment of animals. They belong therefore to that difficult branch of science known by the name of physiology.

GERUND, in grammar, a verbal noun of the neuter gender, partaking of the nature of a participle, declinable only in the singular number, through all the cases except the vocative: as, nom. *amandum*, gen. *amandi*, dat. *amando*, accus. *amandum*, abl. *amando*.

GEROPOGON, a genus of the syngenesia polygamia æqualis class and order. The calyx is simple; recept. with bristle-shaped chaffs; seeds of the disk with feathered down, of the ray with five awns. There are three species, all plants of Italy, having the same habit with the tragopogons.

GESNERIA, a genus of the angiospermia order, in the natural method ranking under the 40th order, personatæ. The calyx is quinquefid, and placed on the germen; the corolla incurved and then recurvated: the capsule inferior and bilocular. There are 12 species, herbs and shrubs of the West Indies.

GETHYLLIS, a genus of the monogynia order, in the dodecandria class of plants, and in the natural method ranking under the 9th order, spathaceæ. The corolla is six cleft, and the stamina are in six different directions; the capsule is trilocular. There are four species, herbs of the Cape.

GEUM, *avens*, or *herb-bennet*, a genus of the polygamia order, in the icosandria class of plants, and in the natural method ranking under the 35th order, senticosæ. The calyx is cleft into ten parts; there are five petals, and each of the seeds has a jointed awn. There are nine species; of which the most remarkable are,

1. The urbanum, with thick fibrous roots, of an aromatic taste: rough, serrated leaves; and upright, round, hairy stalks, terminated by large yellow flowers, succeeded by globular fruit.

2. The rivale, with a very thick, fleshy, and fibrous

root, hairy leaves, and upright stalks 10 or 12 inches high, terminated by purple flowers nodding on one side. Of this there are varieties with red and with yellow flowers. Both of these are natives of Britain, and are easily propagated either by the root or seed. The roots of the first, gathered in the spring before the stems come up, and infused in ale, give it a pleasant flavour, and prevent its growing sour: infused in wine they have a stomachic virtue. The taste is mildly austere and aromatic, especially when the plant grows in warm dry situations; but in moist shady places it has little virtue. Cows, goats, sheep, and swine, eat the plant; horses are not fond of it. The powdered root of the second species will cure tertian agues, and is daily used for that purpose by the Canadians. Sheep and goats eat the plant; cows, horses, and swine, are not fond of it.

GHINIA, a genus of the diandria monogynia class and order. The calyx is five-toothed and acuminate; cor. two-lipped; stam. four, with two barren anthers at the shorter filaments; per. a drupe, containing a four or five-celled nut, with a seed in each cell. There are two species, annuals of the West Indies.

GIANT'S-CAUSEWAY, a vast collection of basaltic pillars in the county of Antrim in Ireland. (See BASALTES.) The principal or grand causeway (for there are several less considerable and scattered fragments) consists of a most irregular arrangement of many hundred thousands of columns: almost all of them are of a pentagonal figure, but so closely and compactly situated on their sides, though perfectly distinct from top to bottom, that scarcely any thing can be introduced between them. The columns are of an unequal height and breadth; some of the highest, visible above the surface of the strand, and at the foot of the impending angular precipice, perhaps about 20 feet, they do not exceed this height, at least none of the principal arrangement. How deep they are fixed in the strand was never yet discovered. This grand arrangement extends nearly 200 yards, visible at low water; how far beyond is uncertain: from its declining appearance, however, at low water, it is probable it does not extend under water to a distance any thing equal to what is seen above. The breadth of the principal causeway which runs out in one continued range of columns, is, in general, from 20 to 30 feet; at one place or two it may be nearly 40 for a few yards. In this account are excluded the broken and scattered pieces of the same kind of construction, that are detached from the sides of the grand causeway, as they do not appear to have ever been contiguous to the principal arrangement, though they have frequently been taken into the width; which has been the cause of such wild and disimilar representations of this causeway, which different accounts have exhibited. The highest part of this causeway is the narrowest, at the very spot of the impending cliff whence the whole projects, where, for four or five yards, it is not above ten or fifteen wide. The columns of this narrow part incline from a perpendicular a little to the westward, and form a slope on their tops, by the unequal height of the columns on the two sides; by which an ascent is made at the foot of the cliff, from the head of one column to the next above, gradatim, to the top of the great causeway, which, at the distance of half a dozen yards from the cliff, obtains a perpendicular position, and, lowering in its general height, widens to about 20 or between 20 and 30 feet, and for 100 yards nearly is always above water. The tops of the columns for this length being nearly of an equal height, they form a grand and singular parade that may be easily walked on, rather inclining to the water's edge. But from high-water mark, as it is perpetually washed by the beating surges on every return of the tide, the platform lowers considerably, and becomes more and more uneven, so as not to be walked on but with the greatest care. At the distance of 150 yards from the cliff it turns a little to the east for 20 or 30 yards, and then sinks into the sea. The figure of these columns is almost unexceptionably pentagonal, or composed of five sides; there are but very few of any other figure introduced: some few there are of three, four, and six sides, but the generality of them are five sided, and the spectator must look very nicely to find any of a different construction: yet what is very extraordinary, and particularly curious, there are not two columns in ten thousand to be found, that either have their sides equal among themselves, or whose figures are alike. Nor is the composition of these columns or pillars less deserving the attention of the curious spectator. They are not of one solid stone in an upright position, but composed of several short lengths, curiously joined, not with flat surfaces, but articulated into each other like a ball and socket, or like the joints in the vertebræ of some of the larger kind of fish, the one end at the joint having a cavity into which the convex end of the opposite is exactly fitted. This is not visible but by disjoining the two stones. The depth of the concavity or convexity is generally about two or three inches. And what is still farther remarkable of the joint, the convexity, and the correspondent concavity, are not conformed to the external angular figure of the column, but exactly round, and as large as the size or diameter of the column will admit; and consequently as the angles of these columns are in general extremely unequal, the circular edges of the joint are seldom coincident with more than two or three sides of the pentagonal, and from the edge of the circular part of the joint to the exterior sides and angles they are quite plain. It is still farther very remarkable likewise, that the articulations of these joints are frequently inverted; in some the concavity is upwards, in others the reverse. This occasions that variety and mixture of concavities and convexities on the tops of the columns, which is observable throughout the platform of this causeway, yet without any discoverable design or regularity with respect to the number of either. The length also of these particular stones, from joint to joint, is various: in general they are from 18 to 24 inches long; and, for the most part, longer towards the bottom of the columns than nearer the top, and the articulation of the joints something deeper. The size or diameter likewise of the columns is as different as their length and figure: in general they are from 15 to 20 inches diameter. There are no traces of uniformity or design discovered throughout the whole combination, except in the form of the joint, which is invariably by an articulation of the convex into the concave of the piece next above or below it; nor are there any traces of a finishing in any part, either in height, length, or breadth, of this curious causeway. If there is here and there a smooth top to any of the columns

above water, there are others just by, of equal height, that are more or less convex or concave, which show them to have been joined to pieces that have been washed, or by other means taken off. And undoubtedly those parts that are always above water have, from time to time, been made as even as might be; and the remaining surfaces of the joints must naturally have been worn smoother by the constant friction of weather and walking, than where the sea, at every tide, is beating upon it, and continually removing some of the upper stones, and exposing fresh joints. And farther, as these columns preserve their diameters from top to bottom, in all the exterior ones, which have two or three sides exposed to view, the same may with reason be inferred of the interior columns whose tops only are visible. Yet, what is very extraordinary and equally curious in this phenomenon is, that notwithstanding the universal dissimilitude of the columns, both as to their figure and diameter, and though perfectly distinct from top to bottom, yet is the whole arrangement so closely combined at all points, that hardly a knife can be introduced between them either upon the sides or angles. And it is a most curious entertainment to examine the close contexture and nice insertion of such an infinite variety of angular figures as are exhibited on the surface of this grand parade. From the infinite dissimilarity of the figure of these colums, this will appear a most surprising circumstance to the curious spectator; and would incline him to believe it a work of human art, was it not, on the other hand, inconceivable that the genius or invention of man should construct and combine such an infinite number of columns, which should have a general apparent likeness, and yet be so universally dissimilar in their figure, as that, from the minutest examination, not two in ten or twenty thousand should be found whose angles and sides are equal among themselves, or of the one column to those of the other. That it is the work of nature there can be no doubt to an attentive spectator, who carefully surveys the general form and situation, with the infinitely various configuration of the several parts of this causeway. There are no traces of regularity or design in the outlines of this curious phenomenon; which, including the broken and detached pieces of the same kind of workmanship, are extremely scattered and confused; and, whatever they might be originally, do not at present appear to have any connection with the grand or principal causeway, as to any supposable design or use in its first construction, and as little design can be inferred from the figure or situation of the several constituent parts. The whole exhibition is, indeed, extremely confused, ununiform, and destitute of every appearance of use or design in its original construction. But what, beyond dispute, determines its original to have been from nature is, that the very cliffs, at a great distance from the causeway, especially in the bay to the eastward, exhibit at many places the same kind of columns, figured and jointed in all respects like those of the grand causeway: some of them are seen near to the top of the cliff, which, in general, in these bays to the east and west of the causeway, is near 300 feet in height; others again are seen about midway, and at different elevations from the strand. A very considerable exposure of them is seen in the very bottom of the bay to the eastward, near 100 roods from the causeway, where the earth has evidently fallen away from them upon the strand, and exhibits a most curious arrangement of many of these pentagonal columns, in a perpendicular position, supporting, in appearance, a cliff of different strata of earth, clay, rock, &c. to the height of 150 feet or more, above. Some of these columns are between 30 and 40 feet high, from the top of the sloping bank below them; and being longest in the middle of the arrangement, shortening on either hand in view, they have obtained the appellation of organs, from a rude likeness in this particular to the exterior or frontal tubes of that instrument; and as there are few broken pieces on the strand near it, it is probable that the outside range of columns that now appears is really the original exterior line, toward the sea, of this collection. But how far they extend internally into the bowels of the incumbent cliff is unknown. The very substance, indeed, of that part of the cliff which projects to a point, between the two bays on the east and west of the causeway, seems composed of this kind of materials; for, besides the many pieces that are seen on the sides of the cliff that circulate to the bottom of the bays, particularly the eastern side, there is, at the very point of the cliff, and just above the narrow and highest part of the causeway, a long collection of them seen, whose heads or tops just appearing without the sloping bank, plainly show them to be in an oblique position, and about half way between the perpendicular and horizontal. The heads of these, likewise, are of mixed surfaces, convex and concave, and the columns evidently appear to have been removed from their original upright, to their present inclining or oblique position, by the sinking or falling of the cliff.

GIBBOUS, in astronomy, a term used in reference to the enlightened parts of the moon, whilst she is moving from the first quarter to the full, and from the full to the last quarter: for all that time the dark part appears horned or falcated, and the light one convex or gibbous.

GIBELINS, or GIBELLINS, a famous faction in Italy, opposite to another, called the Guelphs.

These two factions ravaged and laid waste Italy for a long series of years, so that the history of that country, for the space of two centuries, is no more than a detail of their mutual violence and slaughters. The Gibelins adhered to the emperor against the pope: but concerning their origin, and the reason of their names, we have but a very obscure account. According to the generality of authors, they rose about the year 1240, upon the emperor Frederic II's being excommunicated by pope Gregory IX. Other writers maintain, that the two factions arose ten years before, though still under the same pope and emperor. But the most probable opinion is that of Mainbourg, who says, that the two factions of Guelphs and Gibelins arose from a quarrel between two ancient and illustrious houses on the confines of Germany, that of the Henries of Gibeling, and that of the Guelphs of Adorf.

GIFT, a transferring the property in a thing from one to another without a valuable consideration; for to transfer any thing upon a valuable consideration is a contract of sale: he who gives any thing is called the donor: and he to whom it is given is called the donee.

By the common law all chattels, real or personal, may be granted or given, without deed, except in some spe-

cial cases; and a free gift is good without a consideration, if not to defraud creditors. Park 57.

But no leases, estates, or interests, either of freehold, or term of years, or any uncertain interest not being copyhold or customary interest, of, in, to, or out of, any messuage, manors, lands, tenements, hereditaments, shall at any time be assigned, granted or surrendered, unless it is by deed or act in writing, signed by the party so assigning, granting, or surrendering the same, or their agents thereunto lawfully authorised by writing, or by act and operation of law. 29 Car. II. c. 3. A gift of any thing without a consideration, is good: but it is revocable before delivery to the donee, of the thing given. Jenk. 109 pl. 9.

GILBERTINES, a religious order founded in England by St. Gilbert, in the reign of Henry I. The nuns followed the rule of St. Benedict, and the monks that of St. Augustin. There are many monasteries of this order in different parts of England.

GILD. See Geld.

Gild Merchant, was a certain privilege or liberty granted to merchants, whereby they were enabled, among other things, to hold certain pleas of land within their own precincts; as the gild-merchant granted by king John to the burgesses of Nottingham.

GILDING, is the application of gold to the surfaces of bodies: it is of two principal kinds, according to the method of applying the gold.

Wood, leather, paper, and similar substances, are gilt by fastening on leaves of gold by means of some cement. But metals are gilt by a chemical application of the gold to the surface. This last is called water-gilding.

The gilding of wood, and similar substances, is of three kinds: oil-gilding, burnished gilding, and japanners' gilding, which we shall severally describe, after noticing the materials and tools necessary for the operations.

Of gold-leaf.—There are three kinds of gold-leaf in common use. Pure gold-leaf, which is made by hammering gold till it is sufficiently thin (see Gold-beating). Pale leaf-gold, which has a greenish colour, and is made in the same way of gold alloyed with silver. Dutch gold, which is brought from Holland, and is in fact only copper-leaf coloured by the fumes of zinc. It is much cheaper than true leaf-gold, and is very useful where large quantities of gilding are wanted, which can be defended from the weather, and where great nicety is not required; but it changes its colour entirely when exposed to moisture; and indeed, in all cases, its beauty is soon impaired, unless well secured by varnish. It is therefore only a cheap substitute for true gold leaf, which may be useful where durability is not an object.

Of the instruments necessary for gilding.—The first instrument is the cushion, for receiving the leaves of gold from the books in which they are bought. It is made by covering a board of about eight inches square, with a double thickness of flannel: and over that a piece of buff leather, and fastening it tight round the edges.

The knife for cutting the leaves into the requisite sizes should be made like a pallet knife, and should not have its edge too sharp.

The tip is a tool made by fastening the long hairs of a squirrel's tail between two cards; and is used for taking up the gold-leaf after it is cut, and applying it to the article to be gilded.

A fitch pencil is used for the same purpose as the last, in taking up very small bits of gold-leaf. A ball of cotton is necessary for pressing down the leaf, after it is laid on. A large camel's-hair brush is used for dusting the work, and clearing away the superfluous gold.

Oil-gilding.—First prime your work with boiled linseed-oil and white-lead; and when that is dry, cover it over with a thin coat of gold size, made of stone-ochre ground in fat oil. When that is so dry as to feel clammy to the fingers, or to be what the gilders call tacky, it is fit for gilding. Having spread your leaves upon the cushion, cut them into slips of the proper width for covering your work. Then breathe upon your tip, which, by moistening it, will cause it to take up the leaves from the cushion. Having applied them by the tip on the proper parts of your work, press them down by the ball of cotton. Observe to repair, by putting small pieces of gold on, any parts which you have omitted to cover. When all your work is sufficiently covered, let it dry, and clean it off with the brush.

This sort of gilding is the easiest, least expensive, and stands the weather best, and may be cleaned with a little water at any time; but wants the lustre of burnished gilding.

Burnished gilding.—This is the sort of gilding generally used for picture-frames, looking-glasses, &c.

The wood intended to be gilt in this manner, should first be well sized, and then covered with seven or eight coats of size and whiting, so as to form a body of considerable thickness. Having got a sufficient quantity of whiting upon the work, it must be carefully cleaned, taking care to free all the cavities and hollows from the whiting that may have choked them up, and by proper moulds and tools restoring the sharpness of the mouldings intended to be shown.

It is then to receive a coat of size, which is made by boiling armenian bole with parchment size. This must also remain till it is sufficiently dry for gold. It must not be quite dry, therefore it would not be prudent to lay on more at a time than can be gilt before it becomes too dry.

The work being thus prepared, place it a little declining from you; and having ready a cup of clean water, and some hair-pencils, moisten a part of the work, and then apply the gold by the tip to the moistened part. The gold will immediately adhere close to the work: proceed to wet the next part, and apply the gold as before, repeating this operation till the whole is completed; taking care not to let any drops of water come upon any part of the gold already laid on. Care should therefore be taken that no part be missed in going over it at first, as it is not so easily mended as the oil-gilding.

The work being thus gilt, it is suffered to remain about 24 hours; when the parts that are designed to be burnished, are polished with a dog's tooth, or, what is better, with an agate burnisher. The gilding must not be quite dry when burnished; there is a state proper for the purpose, which is only to be known by experience.

Japanner's gilding.—The gilding of japanned work consists in drawing with a hair-pencil, in gold size, the intended ornaments, and afterwards applying gold-leaf, or gold powder.

The gold size may be prepared in the following man-

ner: Take of linseed oil, and of gum animi, four ounces. Set the oil to boil in a proper vessel, and then add the gum animi gradually in powder, stirring each quantity about in the oil till it appears to be dissolved, and then putting in another, till the whole is mixed with the oil. Let the mixture continue to boil, till, on taking a small quantity out, it appears of a thicker consistence than tar. and then strain the whole through a coarse cloth, and keep it for use; but it must, when applied, be mixed with vermilion and oil of turpentine.

Having laid on the gold size, and suffered it to dry, the gold-leaf is applied in the usual way; or if it is not wanted to shine so much, gold powder is applied, which is made by grinding gold-leaf upon a stone with honey, and afterwards washing the honey away with water. If the gilding is to be varnished over, Dutch gold may be used, or aurum musivum may be used instead of real gold powder.

To write on paper with letters of gold.—Put some gum arabic into common writing-ink, and write with it in the usual way. When the writing is dry, breathe on it; the warmth and moisture soften the gum, and will cause it to fasten on the gold-leaf; which may be laid on in the usual way, and the superfluous part brushed off. Or instead of this, any japanners' size may be used.

To lay gold upon white earthenware, or glass.—Procure some japanners' gold size, and with it draw your design upon the vessel to be gilt, moistening the gold size, as you find necessary, with oil of turpentine. Set your work in a clean place to dry, for about an hour, and then place it so near the fire, that you could but just bear the heat of it with your hand for a few seconds. Let it remain there till it feels quite tacky or clammy; then, having procured a cushion, and some leaf-gold, cut it into slips of the proper size, and lay it on with the little cotton ball. When the gold is all on, put the ware into an oven to be baked for two or three hours.

Glasses, &c. may also be gilt, by drawing the figures with shell gold mixed with gum arabic, and a little borax. Then apply sufficient heat to it; and, lastly, burnish it.

Gilding on glass or porcelain, by burning in.—Dissolve gold in aqua regia, and evaporate the acid by heat, you will obtain a gold powder; or precipitate the gold from the solution by pieces of copper. Lay this gold on with a strong solution of borax and gum water, and it will be ready for burning-in.

Gilding metals.—One method of applying gold upon metals is by first cleaning the metal to be gilt; then gold-leaf is laid on it, which, by means of rubbing with a polished blood-stone, and a certain degree of heat, are made to adhere perfectly well. In this manner silver-leaf is fixed and burnished upon brass, in the making of what is called French plate; and sometimes also gold-leaf is burnished upon copper and iron.

Gilding by amalgamation. A better method is, by previously forming the gold into paste, or amalgam, with mercury.

In order to obtain an amalgam of gold and mercury, the gold is first to be reduced into thin plates or grains, which are heated red-hot, and thrown into mercury previously heated, till it begins to smoke. Upon stirring the mercury with an iron rod, the gold totally disappears. The proportion of mercury to gold is generally as six or eight to one.

The method of gilding by amalgamation is chiefly used for gilding copper, or an alloy of copper, with a small portion of zinc, which more readily receives the amalgam. and is also preferable on account of its colour, which more resembles that of gold than the colour of copper.

When the metal to be gilt is wrought or chased, it ought to be previously covered with quicksilver before the amalgam is applied. that this may be easier spread; but when the surface of the metal is plane, the amalgam may be directly applied to it.

The metal required to be gilt is first rubbed over with a little aquafortis, by which the surface is cleaned from any rust or tarnish that might prevent the union of the two metals. The amalgam being then equally spread over the surface by means of a brush, the mercury is evaporated by a heat just sufficient for that purpose; for if it is too great, part of the gold may also be expelled, and part of it will run together, and leave some of the surface of the metal bare. While the mercury is evaporating the piece is to be, from time to time, taken from the fire, that it may be examined; that the amalgam may be spread more equally by means of a brush; that any defective parts of it may be again covered, and that the heat may not be too suddenly applied to it. When the mercury is evaporated, which is known by the surface becoming entirely of a dull yellow-colour, the metal must then undergo other operations, by which the fine gold-colour is given to it.

First, the gilded piece of metal is rubbed with a scratch-brush (which is a brush composed of brass wire) till its surface is made smooth; then it is covered over with a composition called gilding wax, and is again exposed to the fire till the wax is burnt off. This wax is composed of bee's-wax, frequently mixed with some of the following substances: red ochre, verdigris, copper scales, alum, vitriol, borax; but, according to Dr. Lewis, the saline substances are sufficient, without any wax.

By this operation the colour of the gilding is heightened; and the effect seems to be produced by a perfect dissipation of some mercury remaining after the former operations.

The gilt surface is then covered over with a saline composition, consisting of nitre, alum, or vitriolic salt, ground together, and mixed up into a paste with water or urine. The piece of metal thus covered is exposed to a certain degree of heat, and then quenched in water. By this method its colour is further improved, and brought nearer to that of gold. This effect seems to be produced by the acid of the nitre, (which is disengaged by the sulphuric acid of the alum during the exposure to heat) acting upon any particles of copper which may happen to lie upon the gilded surface.

Lastly. Some artists think that they give an additional lustre to their gilt work, by dipping it in a liquor prepared by boiling some yellow materials, as sulphur, orpiment, or turmeric. The only advantage of this operation is, that part of the yellow matter remains in some of the hollows of the carved work, in which the gilding

is apt to be more imperfect, and to which it gives a rich and solid appearance.

It may here be noticed, that the use of the aquafortis or nitric acid, mentioned in the beginning of the process, is not, as is generally supposed, confined merely to cleansing the surface of the metal to be gilt from rust or tarnish; but it also greatly facilitates the application of the amalgam to the surface of that metal, probably in the following manner: It first dissolves part of the mercury of the amalgam; and when the solution is applied to the copper, this latter metal, having a stronger disposition to unite with the nitrous acid than the mercury has, precipitates the mercury upon its surface, in the same manner as a polished piece of iron precipitates upon its surface copper from a solution of blue vitriol. When the metal to be gilt is thus covered with a thin coat of precipitated mercury, it readily receives the amalgam.

On the subject of gilding by amalgamation, Dr. Lewis has the following remarks: "There are two principal inconveniences in this business; one, that the workmen are exposed to the fumes of the mercury, and generally, sooner or later, have their health greatly impaired by them; the other, the loss of the mercury; for though part of it is said to be detained in the cavities made in the chimneys for that purpose, yet the greatest part of it is lost. From some trials I have made, it appeared that both these inconveniences, particularly the first and most considerable one, might be in a good measure avoided, by means of a furnace of due construction."

If the communication of a furnace with its chimney, instead of being over the fire, is made under the grate, the ash-pit door, or other apertures beneath the grate, closed, and the mouth of the furnace left open, the current of air, which otherwise would have entered beneath, enters now at the top, and passing down through the grate to the chimney, carries with it completely both the vapour of the fuel, and the fumes of such matters as are placed upon it. The back part of the furnace should be raised a little higher above the fire than the fore part, and an iron plate laid over it, that the air may enter only at the front, where the workman stands, who will be thus effectually secured from the fumes, and from being incommoded by the heat, and at the same time have full liberty of introducing, inspecting, and removing, the work.

If such a furnace is made of strong forged (not milled) iron plate, it will be sufficiently durable. The upper end of the chimney may reach above a foot and a half higher than the level of the fire; over this is to be placed a larger tube, leaving an interval of an inch, or more, all round between it and the chimney, and reaching to the height of ten or twelve feet; the higher the better. The external air, passing up between the chimney and the outer pipe, prevents the latter from being much heated, so that the mercurial fumes will condense against its sides into running quicksilver, which falling down to the bottom, is there caught in a hollow rim, formed by turning inwards a portion of the lower part, and conveyed by a pipe at one side into a proper receiver.

Gilding iron or steel. In gilding iron or steel by means of an amalgam, as the metal has no affinity for the mercury, an agent must be employed to dispose the surface to receive the gilding. For this purpose a solution of mercury in nitrous acid (aquafortis), or what the workmen call quicksilver water, is applied to the parts intended to be gilded; the acid, by a stronger affinity, seizes on a portion of the iron, and deposits in the place of it a thin coating of mercury, which will not refuse an union afterwards with the gold amalgam that may be applied; but by this process the surface of the metal is injured by the nitrous acid, and the union of the mercury is very slight, so that a bright and durable gilding cannot be obtained.

Another method. Sometimes a solution of blue vitriol is applied, with a camel's-hair pencil, to the parts of the steel intended to be gilt. By a chemical action, exactly similar to what we have described as taking place when a solution of nitrate of mercury is employed, a thin coating of copper is precipitated on the metal. Copper having an affinity for mercury, a kind of union may by this means be effected between the amalgam and the iron or steel, as the case may be. In whichever of these methods the amalgam is brought into union with the steel, the surface is injured by the action of the acid employed, and still a heat sufficient to volatilize the mercury must be afterwards used.

Gilding of iron by heat. When the surface is polished bright, it must be heated till it becomes blue. Gold leaf is then applied to its surface, and burnished down. It is then heated again, and another layer of gold burnished on it. In this manner three or four coats are given, according to the strength of the gilding intended. This is a more laborious process than the two last, but it is not attended with so much risk.

An improved process for gilding iron or steel. This process, which is less known among artists than it deserves to be, may prove useful to those who have occasion to gild iron or steel. The first part of the process consists in pouring over a solution of gold in nitro-muriatic acid (aqua regia) about twice as much ether, which must be done with caution, and in a large vessel. These liquids must then be shaken together; as soon as the mixture is at rest, the ether will be seen to separate itself from the nitro-muriatic acid, and to float on the surface. The nitro-muriatic acid becomes more transparent, and the other darker than they were before; the reason of which is, that the ether has taken the gold from the acid. The whole mixture is then to be poured into a glass funnel, the lower aperture of which is small; but this aperture must not be opened till the fluids have completely separated themselves from each other. It is then to be opened; by which means the liquid which has taken the lowest place by its greater gravity, viz. the nitro-muriatic acid, will run off: after which, the aperture is to be shut, and the funnel will then be found to contain nothing but ether mixed with the gold, which is to be put into well-closed bottles, and preserved for use. In order to gild iron or steel, the metal must be first well polished with the finest emery, or rather with the finest crocus martis or colcothar of vitriol, and common brandy. The auriferous ether is then to be applied with a small brush; the ether soon evaporates, and the gold remains on the surface of the metal. The metal may then be put into the fire, and afterwards polished. By means of this auriferous ether, all kinds of figures may be delineated on iron, by employing a pen, or fine brush. It is in this

manner, we believe, that the Sohlinger sabre-blades are gilded.

Instead of ether, the essential oils may be used, such as oil of turpentine, or oil of lavender, which will also take gold from its solution.

Gilding of silver. Dissolve gold in the nitro-muriatic acid, and dip some linen rags in the solution; then burn them, and carefully preserve the ashes, which will be very black, and heavier than common. When any thing is to be gilded, it must be previously well burnished; a piece of cork is then to be dipped, first into a solution of salt in water, and afterwards into the black powder; and the piece, after being rubbed with it, must be burnished. The powder is frequently used for gilding delicate articles of silver.

Gilding of brass and copper. Fine instruments of brass, in order that their surface may be kept longer clean, may be gilded in the following manner.

Provide a saturated solution of gold, and having evaporated it to the consistence of oil, suffer it to shoot into crystals. These crystals must then be dissolved in pure water, and the articles to be gilded being immersed in it, are then to be washed in pure water, and afterwards burnished. This process may be repeated several times, till the articles have been well gilt. A solution of gold crystals is preferred to a mere solution of gold, because in the latter there is always a portion of free acid, which will not fail to exercise more or less action on the surface of the brass or copper, and injure its polish.

Grecian gilding. Dissolve some mercury in muriatic acid (spirit of salt), which will give a muriate of mercury. Mix equal parts of this and sal ammoniac, and dissolve them in aquafortis. Put some gold into this, and it will dissolve. When this is applied to silver, it becomes black; but by heating, it assumes the appearance of gilding.

To make shell-gold. Grind up gold-leaf with honey in a mortar; then wash away the honey with water, and mix the gold powder with gum water. This may be applied to any article with a camel's-hair pencil, in the same way as any other colour.

GILT-HEAD. See Sparus.

GIMBALS, a contrivance by means of which barometers, vessels of oil, mariner's compasses, &c. may be suspended so as to arrange their upper parts horizontally. The nature of this contrivance will be at once understood by showing its application to a mariner's compass. It consists of a hoop or ring supported upon two pins diametrically opposite each other, and issuing from the external surface of the ring in such a direction that both lie in the same diametrical line. When the hoop is suspended on these pins, it is at liberty to turn freely about the diameter, of which they constitute the prolongation. The notches or holes of support are disposed horizontally. The compass-box itself is placed in a similar ring with two projecting pivots: and these pivots are inserted in holes made in the former ring at equal distances from each of its pivots. If therefore the whole is left at liberty, the compass-box may vibrate upon the diametrical line of the outer ring, as well as opon a line formed by its own pivots, at right angles to that diametrical line. The consequence of this arrangement is, that the centre of gravity of the compass-box will dispose itself immediately beneath the intersection of both lines on which it is at liberty to move: that is, if the weight of the box and its component parts are properly disposed, the compass will assume a position in which the surface shall be horizontal.

GIN. See Distillation.

Gin, in mechanics, a machine for driving piles, fitted with a windlass and winches at each end, where eight or nine men heave, and round which a rope is reeved, that goes over the wheel at the top: one end of this rope is seized to an iron monkey, that hooks to a beetle of different weights, according to the piles they are to drive, being from eight to thirteen hundred weight; and when hove up to a cross-piece near the wheel it unhooks the monkey, and lets the beetle fall on the upper end of the pile, and forces the same into the ground; then the monkey's own weight overhauls the windlass, in order for its being hooked again to the beetle.

GINANNIA, a genus of the class and order enneandria monogynia. The calyx is double, both one leaved; petals three fringed and spreading; germ pedicelled, with a membranaceous wing at top. Legume. There is one species, a shrub of Guiana.

GINKGO, or maidenhair-tree, of the dioecia class (order and character unknown), a large tree of Japan, with leaves resembling the adiantum, whence its popular name.

GINORA, a genus of the dodecandria monogynia class and order. The calyx is six-clefted; petals six; capsules one-seeded, four-celled, four-valved, coloured, many seeds. There is one species, an elegant shrub of Cuba, bearing handsome large red flowers.

GINGER. See Amomum.

GINSENG. See Panax.

GIRDERS, in architecture, some of the largest pieces of timber in a floor.

By the building act, no girder is to lie less than 10 inches into the wall, and the ends to be laid in loam.

GIRDING-GIRT, in the sea language. A ship is girt, or has a girding-girt, when her cable is so tight or strained, upon the turning of the tide, that she cannot get over it, but lies across the tide.

GIRONNE', or Gironny, in heraldry, a coat of arms divided into girons or triangular figures, meeting in the centre of the shield, and alternately colour and metal.

GISEKIA, a genus of the class and order pentandria pentagynia. The calyx is five-leaved; corolla none; capsules five, approximating, roundish, one-seed. There is one species, an annual of the East Indies.

GLABRASIA, a genus of the class and order polyadelphia polyandria. The calyx is five-cleft; nectarium composed of bristles; stamina 30, always in sixes; perianthium a drupe. There is one species, a large tree of the East Indies.

GLACIES MARIÆ. See Mica.

GLACIS, in fortification, that mass of earth which serves as a parapet to the covered way, sloping easily towards the champaign or field. See Fortification.

GLADIATORS, in antiquity, persons who fought generally in the arena at Rome, for the entertainment of the people.

The gladiators were usually slaves, and fought out of necessity, though sometimes freemen made profession of

it, like our prize fighters, for a livelihood. The Romans borrowed this cruel diversion from the Asiatics. They were all first sworn that they would fight till death; and if they failed they were put to death either by fire, swords, clubs, whips, &c. It was usual with the people or emperor to grant them life when they showed no signs of fear. Augustus decreed that it should always be granted them.

After the engagement, several marks of favour were conferred on the victor, particularly a branch of palm-tree; and often a sum of money, perhaps gathered up among the spectators; but the most common rewards were the pileus and the rudis; the former being given only to such gladiators as were slaves, for a token of obtaining their freedom, but the rudis seems to have been bestowed both on slaves and freemen, with this difference, that it procured the former no more than a discharge from any further performance in public: the rudis, when given to such persons as, being free, had hired themselves out for these shows, restored them to a full enjoyment of their liberty.

From slaves and freedmen, the wanton sport spread to persons of rank, as we find in Nero's time. And Domitian exhibited combats of women in the night-time. We also read that dwarfs encountered with one another. Constantine the Great first prohibited these combats in the East; but the practice was not entirely abolished in the West before Theodoric king of the Ostrogoths, in the year 500.

The dying Gladiator, is a most valuable monument of ancient sculpture, which is now preserved in the palace of Chighi. This man, when he had received the mortal stroke, is particularly careful *ut procumbat honeste*, that he might fall honourably. He is seated in a reclining posture on the ground, and has just strength sufficient to support himself on his right arm; and in his expiring moments it is plainly seen that he does not abandon himself to grief and dejection, but is solicitous to maintain that firmness of aspect which the gladiators valued themselves on preserving in this season of distress, and that attitude which they had learnt of the masters of defence. He fears not death, nor seems to betray any tokens of fear by his countenance, nor to shed one tear. We see, in this instance, notwithstanding his remaining strength, that he has but a moment to live; and we view him with attention, that we may see him expire and fall. Thus the ancients knew how to animate marble, and to give it almost every expression of life.

GLADIOLUS, *corn flag*, a genus of the monogynia order, in the triandria class of plants, and in the natural method ranking under the sixth order, ensatæ. The corolla is sexpartite and ringent, the stamina ascending and bending upwards. There are thirty species, of which the most generally known is the communis or common gladiolus. This has a round, compressed, tuberous root, long sword-shaped leaves, an erect flower-stalk, two or three feet high, the top adorned with several pretty large flowers of a red or white colour, having each six petals. They appear in May and June, and are succeeded by plenty of seed in August. The plants are very hardy, and will thrive in any soil or situation. They are propagated by offsets from the roots. The gladiolus cordinalis is a bulb of the Cape, exquisitely beautiful.

GLAMA. See Camelus.

GLAND. See Anatomy.

GLANDERS. See Farriery.

GLAREOLA, in ornithology, a genus of birds of the order of grallæ. The generic character is: bill strong, short, straight, hooked at the tip; nostrils at the base of the bill linear, oblique; gape of the mouth large; feet four-toed; toes long, slender, connected at the base by a membrane; tail forked, consisting of 12 feathers. There are three species. The austriaca inhabits the heaths of Europe near the banks of rivers, is about nine inches long, feeds on worms and aquatic insects, is very restless and clamorous. See Plate LXVII. Nat. Hist. fig. 214. The senegallensis is found near the Senegal, and in several parts of Siberia: and the nævia is to be met with only in Germany.

GLASS, a transparent, brittle, factitious body, produced by the action of fire upon a fixed salt and sand, or stone, that readily melts.

The fixed alkalies have a strong affinity for several of the earths, particularly for silica and alumina, which they dissolve in considerable quantity, when assisted by heat. When a strong heat is applied to a mixture of fixed alkali and silica, it melts, and forms a transparent mass well known by the name of glass.

The method of making this useful compound was known at an early period. According to Pliny, the discovery was owing to an accident. Some merchants, with a ship-load of soda from Egypt, had cast anchor at the mouth of the river Belus in Phœnicia, and were dressing their dinner on the sand. They made use of large lumps of soda to support their kettles, and lighted fires under them. The heat melted the soda and the siliceous sand together, and the result was glass.

For some time after this accidental discovery, the manufacture of glass was confined to the river Belus. This manufacture seems to have been carried to a considerable degree of perfection among the ancients. They mention drinking-glasses, glass prisms, and coloured glasses of various kinds. But perfectly transparent glass was considered as very valuable; for Nero gave 50,000*l*. for two glass cups with handles; a proof that their processes must have been far less perfect than ours. It was usual for them to melt the materials of their glass into a black mass called ammonitrum, of which statues were sometimes made. This ammonitrum was again melted and purified by refiners. Glass panes seem to have been first used in windows in the third century; but they did not come into common use till long after.

The materials employed in the manufactory of glass may be reduced under three classes, namely, alkalies, earths, and metallic oxides.

The fixed alkalies may be employed indifferently; but soda is preferred in this country. The soda of commerce is usually mixed with common salt, and combined with carbonic acid. It is proper to purify it from both of these foreign bodies before using it. This, however, is seldom done.

The earths are silica, lime, and sometimes a little alumina. Silica constitutes the basis of glass. It is employed in the state of fine sand or flints; and sometimes

for making very fine glass, rock crystal is employed. When sand is used, it ought if possible to be perfectly white; for when it is coloured with metallic oxides, the transparency of the glass is injured. Such sand can only be employed for very coarse glasses. It is necessary to free the sand from all the loose earthy particles with which it may be mixed, which is done by washing it well with water.

Lime renders glass less brittle, and enables it to withstand better the action of the atmosphere. It ought in no case to exceed the twentieth part of the silica employed, otherwise it corrodes the glass pots. This indeed may be prevented by throwing a little clay into the melted glass; but in that case a green glass only is obtained.

The metallic oxides employed are the red oxide of lead or litharge, and the white oxide of arsenic. The red oxide of lead, when added in sufficient quantity, enters into fusion with silica, and forms a glass without the addition of any other ingredient. Five parts of minium and two of silica form a glass of an orange-colour and full of striæ. Its specific gravity is 5. The red oxide of lead renders glass less brittle and more fusible; but when added beyond a certain proportion, it injures the transparency and the whiteness of glass.

The white oxide of arsenic answers the same purposes with that of lead; but on account of its poisonous qualities it is seldom used. It is customary to add a little nitre to the white oxide of arsenic, to prevent the heat from reviving it, and rendering it volatile. When added beyond a certain proportion, it renders glass opaque and milky like the dial-plate of a watch. When any combustible body is present, it is usual in some manufactures to add a little white oxide of arsenic. This supplying oxygen, the combustible is burnt, and flies off; while the revived arsenic is at the same time volatilized.

After mixing the alkali and sand together, it is usual to expose them for some time to a moderate heat. This serves several purposes. It drives off all combustible bodies which may happen to be mixed with the sand; it produces a commencement of combustion which makes the glass afterwards less liable to corrode the clay pots in which it is melted; and the alkali, by this incipient combination, is not so apt to be volatilized, which might be the case if the materials were exposed at once to a violent heat. The mixture, after being thus heated, is called the frit. Through the domes in which the frit is heated, it is usual to see very thin bubbles of glass passing: a proof that some of the materials are volatilized during this first part of the process.

The frit, while still hot, is introduced into large pots made of a mixture of pure clay, and exposed to a heat sufficient to melt it completely. The fusion must be continued till the effervescence occasioned by the separation of the carbonic acid from the soda has subsided, and the opaque scum, known by the name of glass-gall, which collects on the surface of the glass, must be removed. This scum is occasioned by the common salt and other foreign bodies which are always mixed with the soda of commerce. When the fusion has been continued the proper time, the furnace is allowed to cool a little. In that state the glass is exceedingly ductile, and readily assumes any shape that the workmen pleases.

If the glass vessels, after being formed, were cooled rapidly, they would contract unequally, and become in consequence so brittle as to fall to pieces whenever they were handled. To prevent this inconvenience, they are put into a large red-hot furnace, which is allowed to cool very slowly to the temperature of the air. This process is called annealing.

The properties that distinguish good glass are well known. It is perfectly transparent; its hardness is very considerable; its specific gravity varies from 2.8 to 4, according to the proportion of metallic oxide which it contains. When cold it is brittle; but at a red heat it is one of the most ductile bodies known, and may be drawn out into threads so fine as to be scarcely visible to the naked eye. (See Ductility.) It is almost perfectly elastic, and of course is one of the most sonorous of bodies. There are but few chemical agents which have any action on it. Fluoric acid dissolves it with great rapidity, and so do the fixed alkalies when assisted by heat. Dr. Priestley has shown also, that the long-continued action of hot water is capable of decomposing it; a discovery which explains sufficiently the siliceous earth obtained by Boyle and Margraff, when they subjected water to tedious distillations in glass vessels.

There are different kinds of glass manufactured for different purposes: the principal of these are flint glass, crown glass, and bottle glass.

Flint glass is formed of soda, pounded flints, and oxide of lead. It is the densest, most transparent, and most beautiful glass, and is often called crystal. Crown glass contains no lead. It is composed of soda and fine sand. This kind is used for the panes of windows. Bott'e glass is the coarsest of all. It is composed of kelp, or the refuse of soap-boilers, and common sand. Its green colour is owing to the presence of iron. Of these species the most fusible is flint glass, and the least fusible bottle glass. According to the experiments of Saussure, flint glass melts at the temperature of 19° Wedgewood, crown glass at 30°, and bottle glass at 47°.

Glass is often tinged of various colours by mixing with it while in fusion some one or other of the metallic oxides; and on this process, well conducted, depends the formation of pastes or factitious gems.

Blue glass is formed by means of oxide of cobalt.

Green, by the oxide of iron or of copper.

Violet, by oxide of manganese.

Red, by a mixture of the oxides of copper and iron.

Purple, by the purple oxide of gold.

White, by the oxide of arsenic and zinc.

Yellow, by the oxide of silver and by combustible bodies.

Opticians, who employ glass for optical instruments, often complain of the many defects under which it labours. The chief of these are the following:

Streaks. These are waved lines, often visible in glass, which interrupt distinct vision. They are probably owing sometimes to want of complete fusion, which prevents the different materials from combining sufficiently; but in some cases also they may be produced by the workmen lifting up, at two different times, the glass which is to go to the formation of one vessel or instrument.

Tears. These are white specks or knots, occasioned by

the vitrified clay of the furnaces, or by the presence of some foreign salt.

Bubbles. These are air bubbles which have not been allowed to escape. They indicate want of complete fusion, either from too little alkali, or the application of too little heat.

Cords. These are asperities on the surface of the glass, in consequence of too little heat.

Blowing of glass vessels. The furnace for this (fig. 5. Plate Manufacture of Glass) has several mouths, according to the number of workmen. Each mouth consists of three holes, ABD; D is a hole through which the workman takes his metal from the melting-pot; A is the hole at which he afterwards heats his metal; and B is a small hole at which he heats the ends of his blowing-pipe and iron rods *aa*, which are supported by an iron bar across the mouth of the furnace. The furnace is built of fire-bricks, and has three domed chambers, one above another, within it; the fire is made upon a large grate in the middle of the lower one, to which the air is admitted by an arch under ground; the flame goes through an opening in the dome of this chamber, and strikes against the top of the next chamber, and is thereby reverberated upon the pots, which stand upon the floor, just within the hole D; the smoke goes through the floor and roof of the next chamber, which is used as an annealing oven. This furnace is inclosed within a large building, like an inverted funnel, with a chimney at the top.

The principal implements used by the glass-blower are, a blowing-pipe, fig. 1, which is an iron pipe about two feet long, with rope-yarn wrapped round it at A, where the workman takes hold of it; two or three iron rods, fig. 2, of the same length; a pair of blunt shears, fig. 3; and several different sized ladles, shovels, pokers, &c. He has also two stools, figs. 6 and 7, to be hereafter described.

For explaining the operation, we shall describe the method of making a goblet. The workman dips the end D of his blowing-pipe, fig. 1, which is hot, through the hole D, fig. 5, into the melting-pot, which contains the glass in a state of fusion; and by turning it about, a small quantity of the glass, which is called metal, sticks to the iron: this he repeats three or four times (between each dip rolling it on an iron plate, fixed on the stool, fig. 7, to bring it into form) till he has got metal enough: he then blows at the end B of the pipe, which expands the metal into a hollow globular form; and then by swinging it round his head, it lengthens out in the shape of a bladder. The workman then sits down on the stool, fig. 6, between the two bars H and I, across which he lays the blowing-iron, and rolls it along under his left hand, following it at the same time with the shears, fig. 3, in his right hand, the blades *nn* of which embrace it, and by gently putting them in the proper place, he brings the glass into the form shown in fig. 10; meanwhile, the boy who attends him brings a lump of metal from the furnace on the end of one of the iron rods fig. 2, which he sticks on the bottom, or part *a*, fig. 10, and by twisting the rod round, he separates the metal from the rod, and leaves it on the glass vessel; the workman then rolls the rod and vessel as before, and with his shears, as shown in fig. 9, brings the lumps of glass into the form of a stem and foot, as there described. The boy then holds the tool, fig. 4, against the bottom of the foot *b*, while it is turning, to flatten it. The boy next takes another iron rod, fig. 2, and gets a very small piece of metal on its end: this he applies to the centre of the bottom of the foot, so as to connect it to the rod; when the workman, by touching it at the neck *d* with a wet iron, cracks the glass, so that a slight blow upon the rod with the hand will separate it at *d*, from the blowing-pipe M. The glass has by this time become too cold to work without heating again, which is done before the fire A, fig. 5; the workman then returns to the stool, fig. 6, and again rolls the rod round with his left hand as before, and with the point of one of the blades *n* of the shears opens the end *d*, fig. 8, of the glass; after which he inserts both points, and finally works it into the form of fig. 13. It is now separated from the rod N, and is carried on a shovel like a baker's peel by the boy to the annealing furnace, where it remains in a low red-heat for many hours, by which its former extreme brittleness is removed.

Window-glass is made in a similar manner, except that the liquid mass at the end of the tube is formed into a cylindrical shape, which being cut longitudinally by scissars or shears, is gradually bent back until it becomes a flat plate.

Large plate-glass for looking-glasses, &c. is made by suffering the mass in a state of complete fusion to flow upon a table, with iron ledges to confine the melted matter, and as it cools a metallic roller is passed over it, to reduce it to an uniform thickness.

Good glass ware is often ornamented by the glass-cutter before it is offered for sale (see fig. 12); this is generally performed by a machine, fig. 14, wherein AA is a large wheel to be turned by a man at the winch B. The band of this wheel passes round a pulley *a* on the axle of a wheel or cutter C, and thereby turns it with a great velocity: beneath the cutter a cistern D is placed, and above it a small cask E to contain water, the cock *b* of which is so placed and adjusted as to drop very slowly on the circumference of the cutter. The glass-grinder sits down on the stool F, and after dressing the edge of the cutter with emery paste, he applies successively the parts of the glass which are to be cut, as shown in fig. 11, and dexterously moves the glass, as the parts intended to be cut are sufficiently ground away: after this another similar cutter is applied instead of C, or the same is dressed with finer emery paste, or mixture of tripoli and other polishing powders, in order to polish the parts which have been cut; such parts as are intended to have a white appearance are left rough. The cutters *c* are formed of hard wood or soft metal, and the workman is provided with several, of different sizes and thicknesses, particularly at the edge, according to the device which is to be cut on the glass. It is by the fine edge of these cutters that letters, flowers, &c. are cut on glasses by dexterous workmen.

Glass, *painting on.* A few years since, Mr. Farrant obtained a patent for painting, spangling, gilding, and silvering glass, which was performed on the back of the crystal or glass, so as when finished to appear on the front; the colours prepared in oil or varnish as in other works. The parts of ornament which are gold must be first shadowed on the glass, and when dry the gold leaf

must be laid on. Silver ornament is to be done in the same manner. For the spangling, leave the parts to be spangled to the last; then shadow them, and when dry varnish the parts with copal varnish, and strew the spangles on while it is wet; when they are dry, varnish them two or three times.

The ancient manner of painting in glass was very simple, and consequently very easy: it consisted in the mere arrangement of pieces of glass of different colours in some sort of symmetry, and constituted what is now called mosaic work.

In process of time they came to attempt more regular designs, and also to represent figures heightened with all their shades: yet they proceeded no farther than the contours of the figures in black with water colours, and hatching the draperies after the same manner on glasses of the colour of the object they designed to paint. For the carnation, they used glass of a bright-red colour, and upon this they drew the principal lineaments of the face, &c. with black.

But in time, the taste for this sort of painting, improving considerably, and the art being found applicable to the adorning of churches, &c. they found out means of incorporating the colours in the glass itself, by heating them in the fire to a proper degree, having first laid on the colours. The colours used in painting or staining of glass are very different from those used in painting either in water or oil colours.

For black, take scales of iron one ounce, scales of copper one ounce, jet half an ounce; reduce them to powder, and mix them. For blue, take powder of blue one pound, sal nitre half a pound; mix them, and grind them well together. For carnation, take red chalk eight ounces, iron scales and litharge of silver of each two ounces, gum arabic half an ounce; dissolve in water; grind all together for half an hour as stiff as you can; then put it in a glass and stir it well, and let it stand to settle 14 days. For green, take red lead one pound, scales of copper one pound, and flint five pounds; divide them into three parts, and add to them as much nitre; put them into a crucible and melt them with a strong fire; and when it is cold, powder it, and grind it to a porphyry. For gold colour, take silver an ounce, antimony half an ounce; melt them in a crucible; then pound the mass to powder, and grind it on a copper plate; add to it yellow ochre, or brick-dust calcined again, 15 ounces, and grind them well together with water. For purple, take minium one pound, brown stone one pound, white flint five pounds; divide them into three parts, and add to them as much nitre as one of these parts; calcine, melt, and grind it as you did the green. For red, take jet four ounces, litharge of silver two ounces, red chalk one ounce; powder them fine and mix them. For white, take jet two parts, white flint, ground on a glass very fine, one part, mix them. For yellow, take Spanish brown ten parts, leaf silver one part, antimony half a part; put all into a crucible, and calcine them well.

In the windows of ancient churches, &c. there are to be seen the most beautiful and vivid colours imaginable, which far exceed any of those used by the moderns, not so much because the secret of making those colours is entirely lost, as that the moderns will not go to the charge of them, nor be at the necessary pains. Those beautiful works which were made in the glass-houses were of two kinds.

In some, the colour was diffused through the whole substance of the glass. In others, which were the more common, the colour was only on one side, scarcely penetrating within the substance above one third of a line; though this was more or less according to the nature of the colour, the yellow being always found to enter the deepest. These last, though not so strong and beautiful as the former, were of more advantage to the workmen, since on the same glass, though already coloured, they could show other kind of colours where there was occasion to embroider draperies, enrich them with foliage, or represent other ornaments of gold, silver, &c.

In order to this, they made use of emery, grinding or wearing down the surface of the glass, till they were got through the colour to the clear glass. This done, they applied the proper colours on the other side of the glass. By this means, the new colours were hindered from running and mixing with the former, when they exposed the glasses to the fire, as will appear hereafter.

When, indeed, the ornaments were to appear white, the glass was only bared of its colour with emery, without tinging the place with any colour at all; and this was the manner by which they wrought their lights and heightenings on all kinds of colour.

The first thing to be done in order to paint or stain glass in the modern way, is to design and even colour the whole subject on paper. They then choose such pieces of glass as are clear, even, and smooth, and proper to receive the several parts, and proceed to distribute the design itself, or papers it is drawn on, into pieces suitable to those of the glass; always taking care that the glasses may join in the contours of the figures and the folds of the draperies; that the carnations and other finer parts may not be impaired by the lead with which the pieces are to be joined together. The distribution being made, they mark all the glasses as well as papers, that they may be known again; which done, applying every part of the design upon the glass intended for it, they copy or transfer the design upon this glass with the black colour diluted in gum water, by tracing and following all the lines and strokes as they appear through the glass with the point of a pencil.

When these strokes are well dried, which will happen in about two days, the work being only in black and white, they give a slight wash over with urine, gum arabic, and a little black, and repeat it several times, according as the shades are desired to be heightened, with this precaution never to apply a new wash till the former is sufficiently dried.

This done, the lights and risings are given by rubbing off the colour in the places with a wooden point, or the handle of the pencil.

As to the other colours above-mentioned, they are used with gum-water, much as in painting in miniature, taking care to apply them lightly for fear of effacing the outlines of the design; or even, for the greater security, to apply them on the other side; especially yellow, which is very pernicious to the other colours, by blending with them. And here too, as in pieces of black and white, particular regard must always be had not to lay colour

on colour, or lay on a new lay till such time as the former are well dried.

It may be added, that the yellow is the only colour that penetrates through the glass, and incorporates with it by the fire; the rest, and particularly the blue, which is very difficult to use, remaining on the surface, or at least entering very little. When the painting of all the pieces is finished, they are carried to the furnace or oven, to anneal or bake the colours.

The furnace here used is small, built of brick, from 18 to 30 inches square; at six inches from the bottom is an aperture to put in the fuel, and maintain the fire. Over this aperture is a grate, made of three square bars of iron, which traverse the furnace, and divide it into two parts. Two inches above this partition is another little aperture, through which they take out pieces to examine how the coction goes forward. On the grate is placed a square earthen pan, six or seven inches deep, and five or six inches less every way than the perimeter of the furnace. On the one side is a little aperture, through which to make trials, placed directly opposite to that of the furnaces destined for the same end. In this pan are the pieces of glass to be placed in the following manner: First, the bottom of the pan is covered with three strata or layers, of quick lime pulverized; those strata being separated by two others of old broken glass, the design of which is to secure the painted glass from the too intense heat of the fire. This done, the glasses are laid horizontally on the last or uppermost layer of lime.

The first row of glass they cover over with a layer of the same powder, an inch deep; and over this they lay another range of glasses, and thus alternately till the pan is quite full, taking care that the whole heap always end with a layer of the lime-powder.

The pan being thus prepared, they cover up the furnace with tiles, on a square table of earthenware, closely luted all round, only leaving five little apertures, one at each corner, and another in the middle, to serve as chimneys. Things thus disposed, there remains nothing but to give the fire to the work. The fire for the first two hours must be very moderate, and must be increased in proportion as the coction advances, for the space of ten or twelve hours, in which time it is usually completed. At last the fire, which at first was charcoal, is to be of dry wood, so that the flame covers the whole pan, and even issues out at the chimneys.

During the last hours, they make essays, from time to time, by taking out pieces laid for the purpose through the little aperture of the furnace and pan, to see whether the yellow is perfect, and the other colours in good order. When the annealing is thought sufficient, they proceed with great haste to extinguish the fire, which otherwise would soon burn the colours, and break the glasses.

By several statutes, regulations are made for making, importing, and exporting glass, which is to be under the management of the officers of the customs and excise. See Complete Abridgement of the Excise Laws.

GLAUBER's SALT, a cathartic or purging salt. See SODA, *sulphat of.*

GLAUCOPIS, in ornithology, a genus of birds of the order picæ. Bill incurvate, arched, the lower mandible shorter, and carunculate beneath at the base, nostrils depressed, half-covered with a membrane; tongue slit, and fringed at the tip; feet walkers. It inhabits New Zealand.

GLAUX, *milkwort*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 17th order, calycanthemæ. The calyx is monophyllous; there is no corolla; the capsula is unilocular, quinquevalved, and pentaspermous. There is one species.

GLAZIER, an artificer who works in glass. The principal part of a glazier's business consists in fitting panes of glass to the sashes and window-frames of houses, pictures, &c. and in cleaning the same when required.

GLAZIER's VICE, is an instrument for drawing lead: see Plate LXVI. Miscel. fig. 102. PG, QH, are two axles running in the frame KL, ML; C, D, two wheels of iron case-hardened, $1\frac{1}{2}$ inch broad, and of the thickness of a pane of glass; these wheels are fixed to the axles, and run very near one another, their distance not exceeding one-tenth of an inch: across their edges several nicks are cut, the better to draw the lead through. E, F, are two pinions, each of twelve leaves, turning one another and going upon the ends of the axles, which are square, being kept fast there by the nuts P, Q, which are screwed fast with a key. A, B, are two cheeks of iron, case-hardened, and fixed on each side to the case with screws; these are cut with an opening near the two wheels, and set so near to the wheels as to leave a space equal to the thickness of the lead; so that between the wheels and the cheeks there is left a hole of the form represented at N, which is the shape of the lead when cut through. The frame KLML is held together by cross bars passing through the sides, and screwed on; and a cover is put over the machine to exclude the dust. The whole is screwed down fast to a bench by screw-nails LL. When the vice is used, the lead to be drawn is first cast in moulds, into pieces a foot long, with a gutter on each side. One of these pieces is taken, and an end of it sharpened with a knife; then being put into the hole between the wheels, by turning the handle I the lead is drawn through the vice, and receives the form designed.

GLAZING, the crusting over earthen-ware by a vitreous substance, the basis of which is commonly lead. The usual composition for glazing ware is formed of white sand 40 pounds, of red-lead 20 pounds, of pearl-ashes 20 pounds, and of common salt 12 pounds. Powder the sand by grinding it, and then add it to the other ingredients, and grind them together; after which calcine them for some time with a moderate heat, and when the mixture is cold, reduce it to powder, and when wanted for use temper it with water. The proportion of these ingredients may be occasionally varied. The ware, after being turned on the wheel and dried in the open air, is covered over with the above composition by means of a brush; and when set in the furnace, the violent heat soon reduces it to a perfect glass, covering the whole internal and external surface of the vessel. We may observe, however, that lead, being poisonous, ought to be excluded from the composition of glazings, and other fluxes substituted in its stead. A transparent glazing may be prepared without lead by calcining 40 pounds of white sand, 25 pounds of pearl-ashes, and 15 pounds of common salt, and proceeding as before: and a more perfect transparent glazing may be made of sand 40 pounds, of

wood-ashes perfectly burned 50 pounds, of pearl-ashes 10 pounds, and of common salt 12 pounds. The following receipts are taken for the most part from Kunckel, who says that they are the true glazings used at Delft and other Dutch manufactories.

Black is made of eight parts of red-lead, iron-filings three, copper-ashes three, and zaffer two measures. This when melted will make a brown-black, and if wanted blacker, add more zaffer to it.

Blue is thus prepared: Take lead-ashes or red-lead one pound; clear sand or powdered flints two pounds, common salt two pounds, white calcined tartar one pound, Venice or other glass half a pound, zaffer half a pound; mix them and melt them for several times, quenching them always in cold water. If you would have it fine and good, it will be proper to put the mixture into a glass furnace for a day or two. Another blue glazing may be formed of one pound of tartar, a quarter of a pound of red-lead, half an ounce of zaffer, and a quarter of a pound of powdered flints, which are to be fused and managed as in the last receipt. Or, take two pounds of calcined lead and tin, add five pounds of common salt, five pounds of powdered flints, and of zaffer, tartar, and Venetian glass, each one pound. Calcine and fuse the mixture as before. Or again, take of red-lead one part, of sand three parts, and of zaffer one part. For a violet-blue glazing, take four ounces of tartar, two ounces of red-lead, five ounces of powdered flints, and half a dram of manganese.

Brown is made of red-lead and flints, of each 14 parts, and of manganese two parts fused, or of red-lead 12 parts, and manganese one part fused. A brown glazing, to be laid on a white ground, may be made of manganese two parts, and of red-lead and white glass, of each one part, twice fused.

Flesh-coloured is made of 12 parts of lead-ashes, and one of white glass.

Gold-coloured. Take of litharge three parts, of sand or calcined flint one part; pound and mix these very well together, then run them into a yellow glass with a strong fire. Pound this glass, and grind it into a subtile powder, which moisten with a well-saturated solution of silver; make it into a paste, which put into a crucible, and cover it with a cover. Give at first a gentle degree of fire; then increase it, and continue it till you have a glass, which will be green. Pound this glass again, and grind it to a fine powder; moisten this powder with some beer, so that by means of a hair-pencil you may apply it upon the vessels or any piece of earthenware. The vessels that are painted or covered over with this glazing must be first well heated, then put under a muffle; and as soon as the glass runs, you must smoke them by holding them over burning vegetables, and take out the vessels.

Kunckel gives several preparations for a gold-coloured yellow glazing. This may be produced by fusing a mixture of three parts of red-lead, two parts of antimony, and one part of saffron of Mars; by again melting the powdered mass, and repeating the operation four times, or by fusing four or five times a composition of red-lead and antimony, of each an ounce, and of scales of iron half an ounce; or by calcining and fusing together eight parts of red-lead, six parts of flint, one part of yellow ochre, one part of antimony, and one part of white glass. A transparent gold-coloured glazing may be obtained by twice fusing red-lead and white flints, of each 12 parts, and of filings of iron one part.

Green may be prepared of eight parts of litharge or red-lead, eight parts of Venice glass, four parts of brass-dust or filings of copper; or of ten parts of litharge, twelve of flint or pebble, and one of æs ustum or copper ashes. A fine green glazing may be produced by fusing one part of the Bohemian granite, one of filings of copper, one of red-lead, and one of Venetian glass; or by fusing one part of white glass, the same quantity of red-lead, and also of filings of copper; powdering the mass, and adding one part of Bohemian granite to two parts of this powder. A fine green may be obtained by mixing and grinding together any of the yellow glazings with equal quantities of the blue glazings; and all the shades and tints of green will be had by varying the proportion of the one to the other, and by the choice of the kind of yellow and blue.

Sea-green is made of five pounds of lead-ashes, one pound of tin-ashes, three pounds of flint, three quarters of a pound of salt, half a pound of tartar, and half a pound of copper-dust.

Iron-colour is prepared of 15 parts of lead ashes or red-lead, 14 of white sand or flints, and five of calcined copper. This mixture is to be calcined and fused.

Liver-colour is prepared of 12 parts of litharge, eight of salt, six of pebble or flint, and one of manganese.

Purple brown consists of lead-ashes 15 parts, clean sand or powdered flints 18 parts, manganese one part, and white glass 15 measures, to which some add one measure of zaffer.

Red is made of antimony three pounds, litharge or red-lead three, and rust of iron one; grind them to a fine powder. Or, take two pounds of antimony, three of red-lead, and one of calcined saffron of Mars, and proceed as before.

White. The white glazing for common ware is made of 40 pounds of clear sand, 75 pounds of litharge or lead-ashes, 26 of pot-ashes, and 10 pounds of salt; these are three times melted in a cake, quenching it each time in clear cold water. Or it may be made of 50 pounds of clean sand, 70 of lead-ashes, 30 of wood-ashes, and 12 of salt. For a fine white, take two pounds of lead and one of tin; calcine them to ashes: of this take two parts; calcined flint, white sand, or broken white glass, one part; and salt, one part; mix them well together, and melt them into a cake for use. The trouble of calcining the tin and lead may be prevented by procuring them in a proper state. A very fine white glazing may be obtained by calcining two parts of lead and one part of tin, and taking one part of this mass, and of flints and common salt of each one part, and fusing the mixture. A white glazing may be also prepared by mixing 100 pounds of masticot, 60 of red-lead, 20 of calcined tin or putty, and 10 of common salt, and calcining and powdering the mixture several times.

Yellow is prepared of red-lead three pounds, calcined antimony and tin of each two pounds; or, according to some, of equal quantities of the three ingredients. These must be melted into a cake, then ground fine, and this operation repeated several times; or it may be made of 15 parts of lead-ore, three parts of litharge of silver, and 15 parts of sand. A fine yellow glazing may be procured by mixing five parts of red-lead, two parts of powdered

brick, one part of sand, one part of the white glazings, and two parts of antimony, calcining the mixture and then fusing it. Or, take four parts of white glass, one part of antimony, three parts of red-lead, and one part of iron-scales, and fuse the mixture; or fuse 16 parts of flints, one part of iron-filings, and 24 parts of litharge. A light-yellow glazing may be produced with ten parts of red-lead, three parts of antimony, and three of glass, and two parts of calcined tin (see gold colour above). A citron yellow is made of six parts of red-lead, seven parts of fine red brickdust, and two parts of antimony. This mixture must be calcined day and night for the space of four days, in the ash-hole of a glass-house furnace, and at last urged to fusion. See STONE WARE.

GLEANING. It has been said, that by the common law and custom of England the poor are allowed to enter and glean upon another's ground after the harvest, without being guilty of trespass; and this humane provision seems borrowed from the Mosaical law. 3 Black. 212.

But it is now positively settled, by a solemn judgment of the court of common pleas, that a right to glean in the harvest-field cannot be claimed by any person at common law; neither have the poor of a parish, legally settled, such a right. 1 H. Black. Rep. 51—63.

GLEBE. Glebe land is a portion of land, meadow, or pasture, belonging to, or parcel of, the parsonage or vicarage, over and above the tithes. Godolph. Rep. 409.

Glebe lands, in the hands of the parson, shall not pay tithes to the vicar, nor being in the hands of the vicar, shall they pay tithe to the parson. Deggs, Pars. Couns. c. 2.

By stat. 28 H. VIII. c. 11, every successor on a month's warning, after induction, shall have the mansion-house and the glebe belonging thereto, not sown at the time of the predecessor's death. He that is instituted may enter into the glebe land before induction, and plead right against all strangers.

When a parson or vicar has caused any of his glebe lands to be manured and sown, at his own charge, with corn or grain, he may by will devise all the profits and corn growing upon the said glebe; and in case he dies without disposing thereof, his executors shall have the same.

GLECHOMA, *ground-ivy*, a genus of the gymnospermia order, in the didynamia class of plants, and in the natural method ranking under the 42d order, verticillatæ. Each pair of the antheræ come together in the form of a cross; the calyx is quinquefid. There is one species, the hederacea, or common ground-ivy, which is so well known that it requires no description. Many virtues were formerly attributed to this plant, which it is now found not to be possessed of. Some however it has. The leaves are thrown into the vat with ale, to clarify it and give it a flavour. Ale thus prepared is often drunk as an antiscorbutic. The expressed juice, mixed with a little wine, and applied morning and evening, is said to destroy specks upon horses' eyes. The plants that grow near it do not flourish. It is said to be hurtful to horses if they eat much of it. Sheep eat it; horses are not fond of it; cows, goats, and swine, refuse it.

GLEDITSIA, *triple-thorned acacia*, or *honey-locust*, a genus of the diœcia order, in the polygamia class of plants, and in the natural method ranking under the 33d order, lomentaceæ. The hermaphrodite calyx is quadrifid, the corolla tetrapetalous, the stamina six, one pistil and legumen. The male calyx is triphyllous; the corolla tripetalous, with six stamina. The female calyx is pentaphyllous; the corolla pentapetalous, one pistil and legumen.

There is one species. The triacanthos, a native of Virginia and Pennsylvania, is of an upright growth, and its trunk is guarded by thorns of three or four inches in length in a remarkable manner. These thorns have also others coming out of their sides at nearly right angles: their colour is red. The branches are smooth, and of a white colour. These are likewise armed with red thorns, that are proportionably smaller: they are of several directions, and at the ends of the branches often stand single. The young shoots of the preceding summer are perfectly smooth, of a reddish green, and retain their leaves often until the middle of November. Although there is a peculiar oddity in the nature and position of the spines, yet the leaves constitute the greatest beauty of these trees: they are doubly pinnated, and of a delightful shining green. The pinnated leaves that form the duplication do not always stand opposite by pairs on the middle rib; the pinnæ of which they are composed are small and numerous, no less than 10 or 11 pair belong to each of them; and as no less than four or five pair of small leaves are arranged along the middle rib, the whole compound leaf consists often of more than 200 pinnæ of this fine green colour. They sit close, and spread open in fine weather; though during bad weather they will droop, and their upper surfaces nearly join, as if in a sleeping state. The flowers are produced from the sides of the young branches in July: they are a greenish catkin, and make little show; though many are succeeded by pods that have a wonderful effect; for these are exceedingly large, more than a foot, sometimes a foot and a half in length, and two inches in breadth, and of a nut-brown colour when ripe, so that the effect, when hanging on the sides of the branches, may easily be imagined. The seed should be sown in a well-sheltered warm border of light sandy earth. If no border is to be found that is naturally so, it may be improved by applying drift sand, and making it fine. The seeds should be sown about half an inch deep, and they will for the most part come up the first spring. If the summer should prove dry, they must be constantly watered; and if shade could be afforded them in the heat of the day, they would make stronger plants by the autumn. A careful attention to this article is peculiarly requisite; for, as the ends of the branches are often killed, if the young plant has not made some progress, it will be liable to be wholly destroyed by the winter's frost, without protection: and this renders the sowing the seeds in a warm border under a hedge in a well-sheltered place necessary; for there these shrubs will endure the winters even when seedlings, and so will require no farther trouble; nay, though the tops should be nipped, they will shoot out again lower, and will soon overcome it. It will be proper to let them remain two years in the seed-bed before they are planted out in the nursery. The spring is the best time for the work. These trees are late in the spring before

they exhibit their leaves, but keep shooting long in the autumn.

GLINUS, a genus of the pentagynia order, in the decandria class of plants, and in the natural method ranking under the 22d order, caryophyllæi. The calyx is pentaphyllous; there is no corolla; the nectarium is composed of bifid bristles; the capsule is quinquangular, quinquelocular, quinquevalved, and polyspermous. There are three species, herbs of Arabia and the south of Europe.

GLIRES, the name given by Linnæus to the fourth order of the mammalia, the character of which is, foreteeth cutting, two in each jaw; no tusks; feet with claws formed for running and bounding; food, bark, roots, vegetables, &c. which they gnaw. The order includes ten genera, viz. the hystrix, cavia, castor, mus, arctomys, sciurus, myoxus, dipus, lepus, and hyrax.

GLISTER, in surgery, the same with clyster.

GLOBBA, a genus of the monogynia order, in the monandria class of plants. The corolla is equal and trifid, the calyx trifid above, the capsule trilocular, with many seeds. There are four species, herbs of the East Indies.

GLOBE, in geometry, a round or spherical body, more usually called a sphere. See Sphere.

Globe is more particularly used for an artificial sphere of metal, plaister, paper, or other matter, on whose convex surface is drawn a map or representation either of the earth or heavens, with the several circles conceived thereon.

Globes are of two kinds, terrestrial and celestial; each of very considerable use, the one in astronomy, and the other in geography, for performing many of the operations in an easy obvious manner, so as to be conceived without any knowledge of the mathematical grounds of those arts. The fundamental parts, common to both globes, are an axis, representing that of the world, and a spherical shell or cover; which makes the body of the globe, on the external surface of which the representation is drawn.

The globes commonly used are composed of plaister and paper in the following manner. A wooden axis is provided, somewhat less than the intended diameter of the globe, and into the extremes two iron wires are driven for poles: this axis is to be the beam or basis of the whole structure. On the axis are applied two spherical or rather hemispherical caps, formed on a kind of wooden mould or block. These caps consist of pasteboard or paper,l aid one lay after another on the mould, to the thickness of a crown-piece; after which, having stood to dry and embody, making an incision along the middle, the two caps thus parted are slipped off the mould. They remain now to be applied on the poles of the axis, as before they were on those of the mould; and to fix them in their new place, the two edges are sewed together with packthread, &c.

The rudiments of the globe thus laid, they proceed to strengthen and make it smooth and regular. In order to this, the two poles are hasped in a metalline semicircle of the size intended; and a kind of plaister made of whiting, water, and glue, heated, melted, and incorporated together, is daubed all over the paper surface. In proportion as the plaster is applied, the ball is turned round in the semicircle, the edge of which pares off whatever is superfluous, and beyond the due dimension, leaving the rest adhering in places that are short of it. After such application of plaister, the ball stands to dry; which done it is put again in the semicircle, and fresh matter applied: thus they continue alternately to apply the composition and dry it, till the ball every where accurately touches the semicircle; in which state it is perfectly smooth, regular, and complete.

The ball thus finished, it remains to paste the map or description on it. In order to this, the map is projected in several gores or gussets, all which join accurately on the spherical surface, and cover the whole ball. To direct the application of these gores, lines are drawn by a semicircle on the surface of the ball, dividing it into a number of equal parts corresponding to those of the gores, and sub-dividing those again answerably to the lines and divisions of the gores.

The papers thus pasted on, there remains nothing but to colour and illuminate the globe, and to varnish it, the better to resist dust, moisture, &c. The globe itself thus finished, they hang it in a brass meridian, with an hour-circle and a quadrant of altitude, and thus fit it into a wooden horizon.

GLOBES, *use of.* By the assistance of the globes a great number of curious, useful, and entertaining problems are worked, some of which we shall proceed to describe. The globe consists of several parts: as (1) the two poles, being the ends of the axis on which the globe turns, representing the diurnal motion of the earth, and the apparent diurnal motion of the heavens. (2) The brazen meridian, on which are marked the degrees from the equator to the poles. (3) The wooden horizon or frame that supports the whole globe, on which are drawn several circles, as that on which the signs of the zodiac are marked; that containing the calendar or days of the month which correspond to the several degrees of the zodiac; and that on which are delineated the 32 points of the compass. (4) The hour-circle, divided into twice 12 hours, representing the division of time for the day and the night. And, (5) a thin slip of brass, called the quadrant of altitude, useful in several problems to measure the distances and directions of the places from each other.

There are ten principal circles represented upon globes, viz. six greater and four lesser ones. The greater circles are, the brazen meridian, already described; the equinoctial, as it is called on the celestial, and equator on the terrestrial globe; the ecliptic drawn along the middle of the zodiac; and the two colures. The lesser circles, of principal use, are the two tropics and the two polar circles. Of these circles some are fixed, and always obtain the same position; others moveable, according to the position of the observer. The fixed circles are the equator and ecliptic, with their parallels and secondaries; which are usually delineated upon the surface of the globes. The moveable circles are the horizon, with its parallels and secondaries.

The horizon is that great and broad wooden circle surrounding the globe, and dividing it into two equal parts, called the upper and lower hemispheres. It has two notches, to let the brazen meridian slip up and down, according to the different heights of the pole. On the flat

side of this circle are described the twelve signs, the months of the year, the points of the compass, &c. The brazen meridian is an annulus or ring of brass, divided into degrees. It divides the globe into two equal parts, called the eastern and western hemispheres. The quadrant of altitude is a thin pliable plate of brass, answering exactly to a quadrant of the meridian. It is divided into 90°, and has a notch, nut and screw, to fix to the brazen meridian in the zenith of any place, where it turns round a pivot, and supplies the room of vertical circles. The hour-circle is a flat ring of brass, divided into 24 equal parts or hour-distances; and on the pole of the globe is fixed an index that turns round with the globe, and points out the hours upon the hour-circle. Lastly, there are generally added a compass and needle upon the pediment of the frame.

The surface of the celestial globe may be esteemed a just representation of the concave expanse of the heavens, notwithstanding its convexity; for it is easy to conceive the eye placed in the centre of the globe, and viewing the stars on its surface, supposing it made of glass, as some globes are: also that if holes were made in the centre of each star, the eye in the centre of the globe, properly placed, would view through each of the holes the very stars in the heavens represented by them.

As it would be impossible to have any distinct notion of the stars, in respect to their number, order, and distances, without arranging them in certain forms, called constellations, this the first observers of the heavens took care to do; and these, like kingdoms and countries upon the terrestrial globe, serve to distinguish the different parts of the superficies of the celestial globe. The stars, therefore, are all disposed in constellations under the forms of various animals, whose names and figures are represented on the celestial globe, which were first invented by the ancient astronomers and poets, and are still retained for the better distinction of these luminaries.

PROBLEMS ON THE CELESTIAL GLOBE.

1. *To rectify the globe:* that is, to place it in such a particular situation as is necessary for the solution of many problems. Raise or elevate the pole to the latitude of the place; screw the quadrant of altitude in the zenith; set the index of the hour-circle to the upper xii, and place the globe north and south by the compass and needle; then it is a just representation of the heavens for the given day at noon.

2. *To find the sun's place in the ecliptic.* Find the day of the month in the calendar on the horizon, and right against it is the degree of the ecliptic which the sun is in for that day.

3. *To find the sun's declination.* Rectify the globe, bring the sun's place in the ecliptic to the meridian, and that degree which it cuts in the meridian is the declination required.

4. *To find the sun's right ascension.* Bring the sun's place to the meridian, and the degree of the equinoctial cut by the meridian is the right ascension required.

5. *To find the sun's amplitude.* Bring the sun's place to the horizon, and the arch of the horizon intercepted between it and the east or west point, is the amplitude, north or south.

6. *To find the sun's amplitude for any given day and hour.* Bring the sun's place to the meridian, set the hour-index to the upper xii; then turn the globe till the index points to the given hour, where let it stand; then screwing the quadrant of altitude in the zenith, lay it over the sun's place, and the arch contained between it and the horizon will give the degrees of altitude required.

7. *To find the sun's azimuth for any hour of the day.* Every thing being done as in the last problem, the arch of the horizon contained between the north point and that where the quadrant of altitude cuts it, is the azimuth east or west as required.

8. *To find the time when the sun rises or sets.* Find the sun's place for the given day, bring it to the meridian, and set the hour hand to XII; then turn the globe till the sun's place touches the east part of the horizon, the index will show the hour of its rising; after that, turn the globe to the west part of the horizon, and the index will show the time of its setting for the given day.

9. *To find the length of any given day or night.* This is easily known by taking the number of hours between the rising and setting of the sun for the length of the day; and the residue to 24, for the length of the night.

10. *To find the hour of the day, having the sun's altitude given.* Bring the sun's place to the meridian, and set the hour-hand to XII; then turn the globe in such a manner, that the sun's place may move along by the quadrant of altitude (fixed in the zenith) till it touches the degree of the given altitude, where stop it, and the index will show on the horary circle the hour required.

11. *To find the place of the moon, or any planet, for any given day.* Take White's Ephemeris, Nautical Almanac, and against the given day of the month you will find the degree and minute of the sign which the moon or planet possesses at noon, under the title of geocentric motions. The degree thus found being marked in the ecliptic on the globe by a small notch or otherwise, you may then proceed to find the declination, right ascension, latitude, longitude, altitude, azimuth, rising, southing, setting, &c. in the same manner as has been shown for the sun.

12. *To explain the phænomena of the harvest moon.* In order to this we need only consider, that when the sun is in the beginning of Aries, the full moon on that day must be in the beginning of Libra: and since, when the sun sets or moon rises on that day, those equinoctial points will be in the horizon, and the ecliptic will then be least of all inclined thereto, the part or arch which the moon describes in one day, viz. 13°, will take up about an hour and a quarter ascending above the horizon; and, therefore, so long will be the time after sun-set, the next night, before the moon will rise. But at the opposite time of the year, when the sun is in the autumnal and the full moon in the vernal, equinox, the ecliptic will, when the sun is setting, have the greatest inclination to the horizon; and, therefore, 13° will in this case soon ascend, viz in about a quarter of an hour; and so long after sunset will the moon rise the next day after the full: whence at this time of the year, there is much more moonlight than in the spring; and hence this autumnal full moon came to be called the harvest moon, the hunter's or shepherd's moon; all which may be clearly shown on the globe.

13. *To represent the face of the starry firmament for any given hour of the night.* Rectify the globe, and turn it about till the index points to the given hour; then will all the upper hemisphere of the globe represent the visible half of the heavens, and all the stars on the globe will be in such situations as to correspond to those in the heavens, which may therefore be easily found, as will be shown in the 16th problem.

14. *To find the hour when any known star will rise, or come upon the meridian.* Rectify the globe, and set the index to XII; then turn the globe till the star comes to the horizon or meridian, and the index will show the hour required.

15. *To find at what time of the year any given star will be on the meridian at* XII *at night.* Bring the star to the meridian, and observe what degree of the ecliptic is on the north meridian under the horizon; then find in the calendar on the horizon the day of the year against that degree, and it will be the day required.

16. *To find any particular star.* First find its altitude in the heavens by a quadrant, and the point of the compass it bears on; then, the globe being rectified, and the index turned to the given hour, if the quadrant of altitude is fixed on the zenith, and laid towards the point of the compass on which the star was observed, the star required will be found at the same degree of altitude on the said quadrant, as it was by observation in the heavens.

PROBLEMS ON THE TERRESTRIAL GLOBE.

1. *To find the latitude of any place.* Bring the given place to the brazen meridian, and observe what degree it is under, for that is the latitude required.

2. *To rectify the globe for any given place.* Raise the pole so many degress above the horizon as are equal to the latitude of the place; then, finding the sun's place, bring it to the meridian, and proceed as directed in problem 1. on the celestial globe.

3. *To find the longitude of a given place.* Bring the place to the brazen meridian, and observe the degree of the equator under the same, for that expresses the longitude required.

4. *To find any place by the latitude and longitude given.* Bring the given degree of longitude to the meridian, and under the given degree of latitude you will see the place required.

5. *To find all those places which have the same latitude or longitude with those of any given place.* Bring the given place to the meridian; then all those places which lie under the meridian have the same longitude: again, turn the globe round on its axis; then all those places which pass under the same degree of the meridian with any given place have the same latitude with it.

6. *To find all those places where it is noon at any given hour of the day in any place.* Bring the given place to the meridian, set the index to the given hour; then turn the globe till the said index points to the upper XII, and observe what places lie under the brass meridian; for to them it is noon at that time.

7. *When it is noon at any one place, to find what hour it is at any other given place.* Bring the first given place to the meridian, and set the index to the upper XII; then turn the globe till the other given place comes to the meridian, and the index will point to the hour required.

8. *For any given hour of the day in the place where you are, to find the hour of the day in any other place.* Bring the place where you are to the meridian, set the index to the given hour, then turn the globe about; and when the other place comes to the meridian, the index will show the hour of the day there as required.

9. *To find the distance between any two places in English miles.* Bring one place to the meridian, over which fix the quadrant of altitude; and then laying it over the other place, count the number of degrees thereon contained between them; which number multiply by 69½ (the number of miles in one degree), and the product is the number of English miles required.

10. *To find how any one place bears from another.* Bring one place to the brass meridian, and lay the quadrant of altitude over the other, and it will show on the horizon the point of the compass on which the latter bears from the former.

11. *To find those places to which the sun is vertical in the torrid zone for any given day.* Find the sun's place in the ecliptic for the given time, and bring it to the meridian, and observe what degree thereof it cuts; then turn the globe about, and all those places which pass under that degree of the meridian, are those required.

12. *To find what day of the year the sun will be vertical to any given place in the torrid zone.* Bring the given place to the meridian, and mark the degree over it; then turn the globe round, and observe the two points of the ecliptic which pass under that degree of the meridian: lastly, see on the wooden horizon on what days of the year the sun in those points of the ecliptic; for those are the days required.

13. *To find those places in the north frigid zone where the sun begins to shine constantly without setting, on any given day between the 21st of March and the 21st of June.* Find the sun's place in the ecliptic for the given day, bring it to the brazen meridian, and observe the degrees of declination; then all those places which are the same number of degrees distant from the pole are the places required to be found.

14. *To find on what day the sun begins to shine constantly without setting, on any given place in the north frigid zone, and how long.* Rectify the globe to the latitude of the place, and turning it about, observe what point of the ecliptic between Aris and Cancer, and also between Cancer and Libra, coincides with the north point of the horizon; then find, by the calendar on the horizon, what days the sun will enter those degrees of the ecliptic, and they will satisfy the problem.

15. *To find the place over which the sun is vertical on any given day and hour.* Find the sun's place, and bring it to the meridian, and mark the degree of declination for the given hour; then find those places which have the sun in the meridian at that moment; and among them that which passes under the degree of declination is the place desired.

16. *To find, for any given day and hour, those places wherein the sun is then rising and setting, or in the meridian; also those places which are enlightened, and those which are not.* Find the place to which the sun is vertical at the given time, and bring the same to the meridian, and elevate the pole to the latitude of the place; then all those places which are in the western semicircle of

the horizon have the sun rising, and those in the eastern semicircle see it setting; and to those under the meridian it is noon. Lastly, all places above the horizon are enlightened, and all below are in darkness or night.

17. *The day and hour of a solar or lunar eclipse being given, to find all those places in which the same will be visible.* Find the place to which the sun is vertical at the given instant, and elevate the globe to the latitude of the place; then in most of those places above the horizon will the sun be visible during his eclipse; and all those places below the horizon will see the moon pass through the shadow of the earth in her eclipse.

18. *The length of a degree being given, to find the number of miles in a great circle of the earth, and thence the diameter of the earth.* Admit that one degree contains $69\frac{1}{2}$ English statute miles; then multiply 360 (the number of degrees in a great circle) by $69\frac{1}{2}$, and the product will be 25020, the miles which measure the circumference of the earth. If this number be divided by 3.1416, the quotient will be $7963\frac{86}{100}$ miles for the diameter of the earth.

19. *The diameter of the earth being known, to find the surface in square miles, and its solidity in cubic miles.* Admit the diameter to be 7964 miles, then multiply the square of the diameter by 3.1416, and the product will be 199250205 very near, which are the square miles in the surface of the earth. Again, multiply the cube of the diameter by 0.5236, and the product 264466789170 will be the number of cubic miles in the whole globe of the earth.

20. *To express the velocity of the diurnal motion of the earth.* Since a place on the equator describes a circle of 25020 miles in 24 hours, it is evident, that the velocity with which it moves is at the rate of $1042\frac{1}{2}$ in one hour, or $17\frac{3}{10}$ miles per minute. The velocity in any parallel of latitude decreases in the proportion of the co-sine of the latitude to the radius. Thus for the latitude of London, 51° 30′, say,

As radius	10.000000
To the co-sine of lat. 51° 30′	9.794149
So is the velocity in the equator, $17\frac{3}{10}$′	1.232046
To the velocity of the city of London, $10\frac{8}{10}$′	1.032195

That is the city of London moves about the axis of the earth at the rate of $10\frac{8}{10}$ miles every minute of time.

GLOBULAR CHART, a name given to the representation of the surface, or of some part of the surface, of the terrestrial globe upon a plane, wherein the parallels of latitude are circles nearly concentric, the meridian curves bending towards the poles, and the rhomb-lines are also curves.

GLOBULAR SAILING. See SAILING.

GLOBULARIA, *globular blue daisy*, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 48th order, aggregatæ. The common calyx is imbricated, the proper one tubulated inferior, the upper lip of the florets bipartite, the under one tripartite, the receptacle paleaceous. There are eight species, but one only is commonly to be met with in our gardens, viz. the vulgaris, or common blue daisy. It has broad thick radical leaves, three-parted at the ends, upright stalks from about six to ten or twelve inches high, with spear-shaped leaves, and the top crowned by a globular head of fine blue flowers, composed of many florets in one cup. It flowers in June, and makes a good appearance, but thrives best in a moist shady situation. It is propagated by parting the roots in September.

GLORIOSA, *superb lily*, a genus of the hexandria monogynia class of plants, the flower of which consists of six oblongo-lanceolated, undulated, and very long petals, reflex nearly to the base: the fruit is an oval pellucid capsule, containing three cells, and numerous globose seeds, disposed in a double series. There are two species, herbaceous plants of Guinea.

GLOSSOMA, a genus of the tetrandria monogynia class and order. The calyx is turbinate, four-toothed, superior; corolla four-petalled; antheras almost united with membranaceous scales at the end; stigmas four; drupe. There is one species, a shrub of Guiana.

GLOSSOPETALUM, a genus of the pentandria pentagynia class and order. The calyx is five toothed; petals five, with a strap at the tip of each berry. There are two species, trees of Guiana.

GLOSSOPETRA, in natural history, a genus of extraneous fossils, so called from their having been supposed the tongues of serpents turned to stone, though they are really the teeth of sharks, and are found in the mouths of those fishes, wherever taken. The several sizes of teeth of the same species and the several different species of sharks, furnish us with a vast variety of these fossile teeth. Their usual colours are black, bluish, whitish, yellowish, or brown. In shape they are commonly somewhat approaching to triangular; some are simple, and others have a smaller point on each side the larger one; many of them are quite straight, but they are frequently met with crooked, and bent in all the different directions, some inwards, some outwards, and some sideways: they are also of various sizes, the larger ones being four or five inches long, and the smaller less than a quarter of an inch. They are found with us in the strata of blue clay, and are very plentiful in the clay pits of Richmond, and some other places; but they are no where so common as in the island of Malta.

GLOTTIS. See ANATOMY.

GLOVE, a covering for the hand and wrist. Gloves, with respect to commerce, are distinguished into leathern, silk, thread, cotton, worsted, &c. Leathern gloves are made of chamois, kid, lamb, doe, elk, buff, &c. To throw the glove, was a practice or ceremony very usual among our forefathers, being the challenge whereby another was defied to single combat. It is still retained at the coronation of our kings, when the king's champion casts his glove in Westminster-hall. Favyn supposes the custom to have arisen from the Eastern nations, who, in all their sales and deliveries of lands, goods, &c. used to give the purchaser their glove by way of livery or investiture. To this effect he quotes Ruth iv. 7. where the Chaldee paraphrase calls *glove* what the common version renders by *shoe*. He adds, that the rabbins interpret by *glove* that passage in the cviiith Psalm, In Idumean extendam calceamentum meum, "Over Edom will I cast my shoe." Accordingly, among us, he who took up the glove declared thereby his acceptance of the challenge; and as a part of the ceremony, continues Favyn, took the glove off his own right hand and cast it upon the ground, to be taken up by the challenger. This had the force of a mutual engagement on each side,

to meet at the time and place which should be appointed by the king, parliament, or judges. The same author asserts, that the custom which once obtained of blessing gloves in the coronation of the kings of France, was a remain of the Eastern practice of giving possession with the glove, l. xvi. p. 1017, &c. Anciently it was prohibited the judges to wear gloves on the bench; and at present, in the stables of some princes, it is said to be unfafe going in without pulling off the gloves.

GLOW-WORM. See CICINDELA.

GLOXINIA, a genus of the didynamia angiospermia class and order. The calyx is superior, five-leaved; corolla bell-shaped, with the border oblique; filaments with the rudiment of a fifth inserted into the receptacle. There is one species, a herb of South America.

GLUCINA, a new earth, discovered in 1798, in the mountains of Siberia. According to the experiments of Vauquelin and Klaproth, we learn that

1. To obtain glucina pure, the beryl or emerald reduced to powder, is to be fused with thrice its weight of potass. The mass is to be diluted with water, dissolved in muriatic acid, and the solution evaporated to dryness. The residuum is to be mixed with a great quantity of water, and the whole thrown on a filtre. The silica, which constitutes more than half the weight of the stone, remains behind; but the glucina and the other earths, being combined with muriatic acid, remain in solution. Precipitate them by means of carbonat of potass. Wash the precipitate, and then dissolve it in sulphuric acid. Add to the solution sulphat of potass; evaporate it to the proper consistence, and set it by to crystallize. Alum crystals gradually form. When as many of these as possible have been obtained, pour in the liquid carbonat of ammonia to excess, then filtre, and boil the liquid for some time. A white powder gradually appears, which is glucina.

2. Glucina, thus obtained, is a soft light white powder, without either taste or smell, which has the property of adhering strongly to the tongue. It has no action on vegetable colours. It is altogether infusible by heat; neither does it harden or contract in its dimensions, as is the case with alumina. Its specific gravity is 2.967.

It is insoluble in water, but forms with a small quantity of that liquid a paste which has a certain degree of ductility.

3. It does not combine with oxygen nor any of the simple combustibles; but sulphurated hydrogen dissolves it, and forms with it a hydrosulphurat, similar to other hydrosulphurats in its properties.

4. Azote has no action on it; but muriatic acid dissolves it, and forms with it a sweet-tasted salt, called muriat of glucina.

5. Glucina is soluble in the liquid fixed alkalies, in which it agrees with alumina. It is insoluble in ammonia, but soluble in carbonat of ammonia, in which respect it agrees with yttria; but it is about five times more soluble in carbonat of ammonia than that earth.

It combines with all the acids, and forms with them sweet-tasted salts, as is the case also with yttria.

GLUE, among artificers, a tenacious viscid matter, which serves as a cement to bind or connect things together. See GELATINE.

GLUTA, a genus of the class and order pentandria monogynia. The calyx is bell-shaped, deciduous; petals five; filaments inserted into the tip of the column; germ sitting in an oblong column. There is one species, a tree of Java.

GLUTÆUS. See ANATOMY.

GLUTEN. If wheat flour is kneaded into paste with a little water, it forms a tenacious, elastic, soft, ductile mass. This is to be washed cautiously, by kneading it under a small jet of water till the water no longer carries off any thing, but runs off colourless; what remains behind is called gluten. It was discovered by Beccaria, an Italian philosopher, to whom we are indebted for the first analysis of wheat flour.

1. Gluten, when thus obtained, is of a grey colour, exceedingly tenacious, ductile, and elastic, and may be extended to twenty times its original length. When very thin, it is of a whitish colour, and has a good deal of resemblance to animal tendon or membrane. In this state it adheres very tenaciously to other bodies, and has often been used to cement together broken pieces of porcelain. Its smell is peculiar. It has scarcely any taste, and does not lose its tenacity in the mouth. When exposed to the air, it assumes a brown colour, and becomes in a manner covered with a coat of oil.

When exposed to the air, it gradually dries; and when completely dry, it is pretty hard, brittle, slightly transparent, of a dark-brown colour, and has some resemblance to glue. It breaks like a piece of glass, and the edges of the fracture resemble in smoothness those of broken glass; that is, it breaks with a vitreous fracture.

It is insoluble in water, though it imbibes and retains a certain quantity of it with great obstinacy. To this water it owes its elasticity and tenacity. When boiled in water it loses both these properties.

When kept moist, it very soon begins to decompose, and to undergo a species of fermentation. It swells, and emits air-bubbles, which Proust has ascertained to consist of hydrogen and carbonic acid gases. It emits also a very offensive odour, similar to what is emitted by putrefying animal bodies. Cadet kept gluten for a week in a damp room. Its surface became covered with byssi, the fermentation just mentioned had commenced, and the odour was distinctly acid. In 24 days, on removing the upper crust, the gluten was found converted into a kind of paste, of a greyish white colour, not unlike bird-lime. In that state he gave it the name of fermented gluten. If the gluten is still left to itself, it gradually acquires the smell and taste of cheese. This curious fact was first ascertained by Rouelle junior, to whom we are indebted for the most important dissertation on gluten which has yet appeared. In that state it is full of holes, and contains the very same juices which distinguish some kinds of cheese. Proust ascertained that it contains ammonia and vinegar; bodies which Vauquelin detected in cheese: and ammonia robs both equally of their smell and flavour.

When moist gluten is suddenly dried, it swells amazingly. Dry gluten, when exposed to heat, cracks, swells, melts, blackens, exhales a fetid odour, and burns precisely like feathers or horn. When distilled, there comes over water impregnated with ammonia and an empyreumatic oil; the charcoal which remains is with difficulty reduced to ashes.

2. Gluten is insoluble in water; it is equally insoluble

in alcohol and in ether. But when the fermented gluten of Cadet is triturated with a little alcohol into a mucilage, and then mixed with a sufficient quantity of that liquid, a portion of it is dissolved. This solution constitutes an excellent varnish, possessed of considerable elasticity. It may be spread over paper or wood; and when dry resists other bodies as well as most varnishes. In this state too it may be employed to cement china; and triturated with paints, especially vegetable colours, it forms a very good ground. When this solution is mixed with a sufficient quantity of lime, it forms a very good lute; and bits of linen dipt in it adhere very strongly to other bodies.

All the acids dissolve it, even when very much diluted; alkalies precipitate it again, but it is deprived of its elasticity, and brought nearer to the state of extractive matter. Concentrated sulphuric acid renders it violet-coloured, and at last black; inflammable air escapes, and charcoal, water, and a portion of ammonia, are formed. When nitric acid is poured on it, and heat applied, there is a quantity of azotic gas emitted, as Berthollet discovered; and by continuing the heat, some little oxalic acid is formed, and likewise malic acid, while a number of yellow-coloured oily flakes make their appearance in the solution. Acetic acid acts but imperfectly, but it dissolves the fermented gluten of Cadet; and the solution may be substituted for the solution in alcohol as a varnish; but it does not answer to mix it with colours.

Alkalies dissolve gluten when they are assisted by heat. The solution is never perfectly transparent. Acids precipitate the gluten from alkalies, but it is destitute of its elasticity. Alkalies, when much concentrated, form with it a kind of soap, converting it into oil and ammonia, which last is dissipated during the trituration.

The action of the metallic oxides and their salts upon gluten has not been tried.

It has a strong affinity for the colouring matter of vegetables, and likewise for resinous bodies.

3. The properties of this substance clearly point out a resemblance between it and animal matter; and the phenomena of its fermentation and destructive distillation show us that oxygen, hydrogen, carbon, and azote, are constituents of it. Proust has observed, that the vapour which it emits, while fermenting, blackens silver and lead, and of course contains sulphur.

4. Like all other vegetable principles, gluten is susceptible of various shades of properties, which constitute so many species. In wheat flour, it occurs in the greatest abundance, and from it we can extract it with the greatest ease. But the sagacity and industry of Rouelle and Proust have detected its presence in many other vegetable substances. Rouelle found it in the leaves of all the vegetable substances which he examined. The exactness of this opinion was called in question by Fourcroy, who treated the experiments of Rouelle with contempt; but it has been lately examined and confirmed by very decisive experiments of Proust.

When the juice of cabbage-leaves, cresses, scurvy-grass, and other similar plants, is extracted by pressure, and passed through a cloth, it still continues far from transparent. Its muddiness is owing to a fine soft silky green powder suspended in it, which subsides to the bottom so slowly as to take at least a week before it is deposited. This green powder has been distinguished by the name of the green fecula of plants. Rouelle first examined it with attention, and ascertained its properties; and the subject has been carried still farther by Proust. The slowness with which it subsides shows that its specific gravity does not differ much from that of water. When once it has fallen, it is insoluble. This substance consists chiefly of three principles: 1. A green matter to which it owes its colour, separated by digestion in alcohol, and which possesses the properties of a resin. 2. A substance which consists chiefly of woody fibres, and which is left behind when the fecula is digested in potass. 3. A species of gluten, which constitutes the greatest part of it, and to which it owes its characteristic properties.

When the juice of the plants is exposed to a heat of about 130°, the green fecula undergoes a kind of coagulation, concreting into large flakes, which subside very quickly. At this temperature, albumen is not altered by heat. This is the method commonly taken to clarify these juices. We see from it, that the fecula was united to the water by a very small force, which the addition of heat weakened sufficiently to enable the gluten to cohere. This coagulation by heat takes place how diluted soever the juices are with water, which is by no means the case with albumen. It is thrown down also by the addition of a little alcohol, by all acids, by ammonia, by sulphurated hydrogen gas, or by throwing into the liquid crystals of carbonat of potass, magnesia, common salt, muriat of potass, nitre, sal ammoniac, &c.

When separated from water, it soon dries, and becomes elastic, and has somewhat of the appearance of horn; and in that state is scarcely softened by hot water. When treated like gluten, it gradually acquires the cheesy taste and smell. When kept under water, it very soon begins to putrefy, and exhales a gas which blackens silver and solutions of lead. This speedy putrefaction in stagnant water takes place when flax and hemp are steeped. These substances contain green fecula in their rind, and the putrefaction occasions the separation of the whole, which could not otherwise be accomplished. The water which has been allowed to remain for a whole year over green fecula, contains sulphurated hydrogen, carbonat of ammonia, and gluten seemingly held in solution by the ammonia. The stench of putrefaction still continues even after the water has been boiled.

5. The number of plants containing gluten is very considerable. Proust found it in acorns, chesnuts, horse-chesnuts, rue, barley, rye, peas, and beans; and in apples and quinces. He found it also in the leaves of cabbage, sedums, cress, hemlock, borage, saffron, &c.; in the berries of the elder, the grape, &c.; in the petals of the rose, &c. It occurs also in several roots. Proust could find none in the potatoe.

6. Gluten must be considered as one of the most useful of the vegetable principles. It constitutes an essential ingredient in wheat, and is the substance which renders flour of wheat so fit for forming bread. It seems also to constitute the essential part of yeast. Its uses as a varnish, a ground for paint, &c. pointed out by Cadet, likewise deserve attention. The gluten of wheat is said, in many cases at least, to constitute the base of the substance called bird-lime; though that substance is supposed to be a preparation obtained from the bark of the

elm, &c. and in that case is, according to Proust, a kind of turpentine or resin, soluble in alcohol, and not in the least resembling gluten.

GLYCONIAN VERSE, in ancient poetry, consists of three feet, whereof the first is a spondee, the second a choriambus, and the last a pyrrhichius; or the first may be a spondee, and the other two dactyls.

Thus, *Mens re-* | *gnum bona pos-* | *sidet-*
or, *Mens re-* | *gnum bona* | *possidet.*

GLYCINE, *knobbed-rooted liquorice-vetch*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The calyx is bilabiate; the carina of the corolla turning back the vexillum with its point. There are 25 species, one of which is commonly cultivated in our gardens, the frutescens, or Carolina kidney-bean tree. This has shrubby climbing stalks, twining round any support, 15 or 20 feet high, adorned with pinnated leaves of three pair of follicles terminated by an odd one, and from the axillas clusters of large bluish purple flowers, succeeded by long pods like those of the climbing kidney-bean. It flowers in June and July. It is easily propagated, either by seeds or by layers.

The glycino coccinea is an elegant little plant, lately introduced into our stoves, and easily propagated by seed.

GLYCIRRHIZA, *liquorice*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The calyx is bilabiate; the upper lip tripartite, and the under one entire; the legumen ovate and compressed. There are four species. The glabra, or common liquorice, has a long, thick, creeping root, striking several feet deep into the ground; upright, firm, herbaceous stalks annually, three or four feet high, with winged leaves of four or five pair of oval lobes, terminated by an odd one; and from the axillas erect spikes of pale-blue flowers, which appear in July, succeeded by short smooth pods. The root of this is the useful part, which is replete with a sweet, balsamic, pectoral juice, much used in all compositions for coughs and disorders of the stomach. The echinata, or prickly-podded liquorice, is nearly like the common sort, only the seed-pods are prickly. Both these species are very hardy perennials; but the first is the sort commonly cultivated for use, its roots being fuller of juice and sweeter than the other. The roots are perennial; but the stalks rise in spring and decay in autumn.

Their propagation is effected by cuttings of the small roots issuing from the sides of the main ones near the surface of the earth, dividing them into lengths of six or eight inches, each having one or more good buds or eyes; and the proper season for procuring the sets for planting is any time in open weather from October till March, though from the middle of February till the middle of March is rather the most successful season for planting. An open situation is the most suitable for a plantation of these plants. Particular regard should also be had to the soil; it ought to be of a light loose composition, and three or four feet deep if possible; for the roots of the liquorice will arrive at that depth and more, and the longer the roots the more valuable they are for sale by weight.

In three years after planting, the roots of the liquorice will be fit to take up; and the proper season for this is any time from the beginning of November till February; for it should neither be taken up before the stalks are fully decayed, nor deferred till late in the spring, otherwise the roots will be apt to shrivel, and diminish in weight. In taking them up, the small side-roots are trimmed off: and the best divided into lengths for fresh sets, and the main roots are tied in bundles ready for sale.

Liquorice is almost the only sweet that quenches thirst; whence it was called by the Greeks adipson. Galen takes notice, that it was employed in this intention in hydropic cases, to prevent the necessity of drinking. Mr. Fuller, in his Medicina Gymnastica, recommends this root as a very useful pectoral; an assertion warranted by experience. An extract is directed to be made from it in the shops; yet this preparation is chiefly brought from abroad, though the foreign extract is not the best.

GMELINA, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is nearly quadridentated; the corolla campanulated or bell-shaped; there are two bipartite and two simple antheræ; the fruit is a plum with a bilocular kernel. There is one species, a tree of Malabar.

GNAPHALIUM, *cudweed, goldy locks, eternal flower*, &c. a genus of the polygamia superflua order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; the pappus feathered; the calyx imbricated, with the marginal scales roundish, parched, and coloured. There are 66 species; the most remarkable of which are: 1. The margaritaceum, or pearly white eternal flower, has creeping, very spreading roots, crowned with broad spear-shaped, white, hoary leaves; herbaceous, thick, woolly stalks, a foot and a half high, branching outward, with long, acute pointed, white, woolly leaves, and terminated by a corymbose cluster of yellowish flowers, which appear in June and July, and are very ornamental. 2. The plantaginium has large woolly radical leaves, decumbent running roots, and herbaceous simple stalks, rising six or eight inches, terminated by a corymbus of white flowers, which appear in June, July, &c. 3. The stechas has a shrubby stalk, dividing into slender branches three feet long, terminated by corymbose clusters of yellow flowers, appearing in May and June. 4. The orientale has three varieties, with yellow, gold-coloured, and white silvery flowers. They have shrubby stalks, rising two or three feet high. 5. The odoratissimum, or sweet-scented eternal flower, has shrubby winged stalks, branching irregularly a yard high, with corymbose clusters of bright yellow flowers, changing to a dark yellow. 6. The arboreum, or tree gnaphalium, has a woody stem, branching four or five feet high, narrow sessile leaves, with revolute borders, smooth on their upper side, and roundish bunches of pale yellow flowers. The first three sorts are hardy, and will thrive in any soil or situation. The first two increase exceedingly by their roots; and the third is easily propagated by slips. The fourth, fifth, and sixth sorts are somewhat tender, and therefore should be kept in pots, to be sheltered in a green-house or garden-frame in winter. Others may be planted in the full ground, in a dry and warm situation, especially the oriental kind

and varieties, and likewise the sweet-scented kind; for these two species will struggle tolerably through an ordinary winter, and make a pretty appearance during the summer months. All these are propagated by slips or cuttings of their shoots. The flowers of all these species are remarkable for retaining their beauty for years, if carefully gathered in a dry day, soon after they are blown.

GNAT. See CULEX.

GNEISS, in mineralogy, is composed essentially of felspar, quartz, and mica, forming plates which are laid on each other, and separated by thin layers of mica. It differs from granite in being shistose. Gneiss rocks are usually stratified. Like granite, it sometimes contains shorl and garnet. The beds of gneiss sometimes alternate with layers of granular limestone, shistose, hornblende, and porphyry. It is rich in ores, almost every metal having been found in gneiss rocks, either in veins, or beds.

GNETUM, a genus of the monadelphia order, in the monœcia class of plants. The amentum of the male is a single scale; there is no corolla, and but one filament with a pair of antheræ. The calyx of the female is of the same form; there is no corolla; the style with the stigma is trifid; the fruit a monospermous plum. There is one species, a herb of the East Indies.

GNIDIA, a genus of the monogynia order, in the octandria class of plants. The calyx is funnel-shaped and quadrifid, with four petals inserted into it; there is one seed somewhat resembling a berry. There are 11 species, shrubs of the Cape.

GNOMON, in dialling, the style, pin, or cock of a dial, which by its shadow shows the hour of the day. The gnomon of every dial represents the axis of the world. See DIAL and DIALLING.

GNOMON, in geometry. If in a parallelogram A B C D (plate LXIV. Miscel. fig. 103.) the diameter A C be drawn; also two lines E F, H I, parallel to the sides of the parallelogram, and cutting the diameter in one and the same point G, so that the parallelogram is, by these parallels, divided into four parallelograms, then are the two parallelograms DG, BG, through which the diameter does not pass, called complements; those through which the diameter passes, EH, FI, are called the parallelograms about the diameter; and a gnomon consists of the two complements, and either of the parallelograms about the diameter, viz. GD+HE+EI, or GD+FI+GB.

GNOMON, in astronomy, a style erected perpendicular to the horizon, in order to find the altitude of the sun. Thus, in the right-angled triangle ABC, fig. 104. are given AB the length of the style, BC the length of its shadow, and the right angle ABC. Hence, making CB the radius, we have this analogy for finding the angle ACB, the sun's altitude, viz. BC : AB : : radius : tangent of the angle C. By means of a gnomon, the sun's meridian altitude, and consequently the latitude of the place, may be found more exactly than with the smaller quadrants. See QUADRANT.

By the same instrument the height of any object GH may be found; for as DF (fig. 105) the distance of the observer's eye from the gnomon, is to DE, the height of the style, so is FH, the distance of the observer's eye from the object, to GH its height.

The following example will serve to illustrate the above proposition. Pliny says, that at Rome, at the time of the equinoxes, the shadow is to the gnomon as 8 to 9; therefore as 8 : 9 : : 1 or radius : $\frac{9}{8} = 1{\cdot}125$ a tangent, to which answers the angle 48° 22′, which is the height of the equator at Rome, and its complement 41° 38′ is therefore the height of the pole, or the latitude of the place.

Riccioli remarks the following defects in the observations of the sun's height, made with the gnomon by the ancients, and some of the moderns, viz. that they neglected the sun's parallax, which makes his apparent altitude less, by the quantity of the parallax, than it would be if the gnomon were placed at the centre of the earth: 2d, they neglected also the refraction, by which the apparent height of the sun is a little increased: and 3dly, they made the calculations from the length of the shadow, as if it were terminated by a ray coming from the centre of the sun's disc; whereas the shadow is really terminated by a ray coming from the upper edge of the sun's disc; so that, instead of the height of the sun's centre, their calculations gave the height of the upper edge of his disc: and, therefore, to the altitude of the sun found by the gnomon, the sun's parallax must be added, and from the sum must be subtracted the sun's semidiameter, and refraction, which is different at different altitudes; which being done, the correct height of the equator at Rome will be 48° 4′ 12″, the complement of which, or 44° 55′ 46″, is the latitude.

The preceding problem may be resolved more accurately by means of a ray of light let in through a small hole, than by a shadow, thus: make a circular perforation in a brass plate EF (fig. 106.) to transmit enough of the sun's rays to exhibit his image on the floor, or a stage; fix the plate parallel to the horizon in a high place, proper for observation, the height of which above the floor let be accurately measured with a plummet. Let the floor, or stage, be perfectly plane and horizontal, and coloured over with some white substance, to show the sun more distinctly. Upon this horizontal plane draw a meridian line passing through the foot or the centre of the gnomon, AG, *i. e.* the point upon which the plummet falls from the centre of the hole; and upon this line, note the extreme points I and K of the sun's image or diameter, and from each end subtract the image of half the diameter of the aperture, viz. KH and LI; then will HL be the image of the sun's diameter, which, when bisected in B, gives the point on which the rays fall from the centre of the sun.

Now having given the line AB, and the altitude of the gnomon AG, besides the right angle A, the angle B, or the apparent altitude of the sun's centre, is easily found, thus: as AB : AG : : radius: tang. angle B.

GNOSTICS, in church-history, christians so called, it being a name which almost all the ancient heretics affected to take to express that new knowledge and extraordinary light to which they made pretensions: the word gnostic signifying a learned or enlightened person.

GOAT. See CAPRA.

GOAT-SUCKER. See CAPRIMULGUS.

GOBIUS, GOBY, in ichthyology, a genus of fishes

belonging to the order of thoracici. The generic character is, head small; eyes approximated; gill-membrane four rayed; ventral fins united into the form of a funnel. There are eight species, of which the following are the principal.

1. Gobius niger. Common goby. This species grows to the length of six inches; the body is soft, slippery, and of a slender form; the head rather large; the cheeks inflated; the teeth small, and disposed in two rows; from the head to the first dorsal fin is a small furrow; the first dorsal fin consists of six rays, the second, according to Linnæus, of fourteen; the pectoral of sixteen or seventeen, closely set together, and the middlemost the longest; the others on each side gradually shorter; the ventral fins coalesce, and form a sort of funnel, by which these fish are said to affix themselves immoveably to the rocks, for which reason they are called by the name of rock-fish; the tail is rounded at the end; the general colour of the fish is dusky or blackish; but this, on close inspection, is owing to numerous small dusky or blackish specks, accompanied by brown or olive-coloured bars and clouds disposed on a whitish ground; the dorsal and anal fins are of a pale blue; the rays marked with minute black spots. This fish is a native of the Mediterranean and northern seas, and sometimes enters the mouths of the larger rivers, particularly in the beginning of summer, at which season it deposits its spawn on stones near the shores. It is in the number of edible fish, but is in no particular estimation.

2. Gobius lanceolatus. Lance-tailed goby. This species is distinguished by the peculiar form of its tail, which is large in proportion to the animal, and sharp-pointed at the tip; the body is of a lengthened shape, and nearly of an equal diameter throughout; the head is oblong, and truncated in front; the jaws of equal length, and armed with sharp teeth; the gill-covers consist of two small laminæ, and the opening of the gills is large; the vent is situated much nearer the head than the tail; the body is covered with scales, of which those toward the tail are much larger than those on the upper parts. This is a West Indian species: it is found in the rivers of Martinique and some other islands.

3. Gobius cæruleus. Blue goby. Described by Cepede from Commerson. A highly beautiful, though very small, species; colour fine blue, rather paler beneath; tail red, with a black border; length about a decimetre; mouth obtuse; teeth in the lower jaw sharp, and rather longer than those of the upper; eyes rather more distant than in others of the genus; body covered with small rough scales; first dorsal fin triangular, with the rays terminating in lengthened filaments; second dorsal terminated by a ray of twice the length of the rest; vent placed nearly in the middle of the body; tail rounded. Inhabits the seas about the eastern coast of Africa, where it is used by the negroes as a bait for other fish. From the brilliancy of its colours it appears, when swimming in a calm sea, during a bright sunshine, like a small tube of sapphire, tipped with carbuncle.

4. Gobius jozo. Blue-finned goby. This species grows to the length of four or six inches, and is principally distinguished by the blue colour of its fins, and the streaks on the first dorsal fin; the jaws are of equal length, and armed with small sharp teeth; the lateral line runs in a straight direction along the middle of the body. It is a native of the Mediterranean and the Baltic, and commonly frequents the muddy shores, living on sea-insects, &c. It deposits its spawn on the soft mud; and though very prolific, is not observed to be very numerous, owing to the small fry becoming the prey of other fishes; as a food it is held in little or no esteem.

GODFATHERS and Godmothers, persons who at the baptism of infants lay themselves under an indispensable obligation to instruct them, and watch over their conduct. This custom is of great antiquity in the christian church, and was probably instituted to prevent children being brought up in idolatry, in case their parents died before they arrived at years of discretion. The number of godfathers and godmothers is reduced to two in the church of Rome, and three in the church of England; but formerly they had as many as they pleased.

GOLD. See Aurum, and Chemistry.

Gold-wire, a cylindrical ingot of silver, superficially gilt, or covered with gold at the fire, and afterwards drawn successively through a great number of little round holes, of a wire drawing-iron, each less than the other, till it is sometimes no bigger than a hair of the head. See Wiredrawing.

It may be obeved, that before the wire is reduced to this excessive fineness, it is drawn through above 140 different holes, and that each time they draw it, it is rubbed afresh over with new wax, both to facilitate its passage, and to prevent the silver appearing through it.

Gold-wire, *flatted*, is the former wire flatted between two rollers of polished steel, to fit it to be spun on a stick, or to be used flat, as it is without spinning, in certain stuffs, laces, embroideries, &c.

Gold-thread, or *spun-gold*, is a flatted gold, wrapped or laid over a thread of silk, by twisting it with a wheel and iron bobbins.

Manner of forming gold-wire and gold-thread, both round and flat. First, an ingot of silver, of 24 pounds, is forged into a cylinder, of about an inch in diameter; then it is drawn through eight or ten holes, of a large coarse wiredrawing-iron, both to finish the roundness, and to reduce it to about three-fourths of its former diameter. This done, they file it very carefully all over to take off any filth remaining from the forge; they then cut it in the middle: and thus make two equal ingots thereof, each about 26 inches long, which they draw through several new holes, to take off any inequalities the file may have left, and to render it as smooth and equable as possible.

The ingot thus far prepared, they heat it in a charcoal fire; then taking some gold-leaves, each about four inches square, and weighing twelve grains, they join four, eight, twelve, or sixteen of these, as the wire is intended to be more or less gilt; and when they are so joined as only to form a single leaf, they rub the ingots reeking-hot with a burnisher. These leaves being thus prepared, they apply over the whole surface of the ingot, to the number of six, over each other, burnishing or rubbing them well down with the blood-stone, to close and smooth them. When gilt, the ingots are laid anew in a coal fire; and when raised to a certain degree of heat, they go over them a second time with the blood-stone, both to solder the gold more perfectly, and to finish the polishing. The gilding finished, it remains to draw the ingot into wire.

In order to do this, they pass it through 20 holes of a moderate drawing-iron, by which it is brought to the thickness of the tag of a lace: from this time the ingot loses its name, and commences gold-wire. Twenty holes more of a lesser iron leave it small enough for the least iron, the finest holes of which last, scarcely exceeding the hair of the head, finish the work.

To dispose the wire to be spun on silk, they pass it between two rollers of a little mill; these rollers are of nicely polished steel, and about three inches in diameter. They are set very close to each other, and turned by means of a handle fastened to one of them, which gives motion to the other. The gold-wire in passing between the two is rendered quite flat, but without losing any thing of its gilding, and is rendered so exceedingly thin and flexible, that it is easily spun on silk thread, by means of a hand-wheel, and so wound on a spool or bobbin.

Gold-*beating*. They first melt a quantity of pure gold, and form it into an ingot: this they reduce, by forging, into a plate of about the thickness of a sheet of paper; which done, they cut the plate into little pieces about an inch square, and lay them in the first or smallest mould to begin to stretch them; after they have been hammered here awhile with the smallest hammer, they cut each of them into four, and put them into the second mould, to be extended further.

Upon taking them hence, they cut them again into four, and put them into the third mould, out of which they are taken, divided into four as before, and laid in the last or finishing mould, where they are beaten to the degree of thinness required.

The leaves thus finished, they take them out of the mould, and dispose them into little paper books, prepared with a little red bole, for the gold to stick to: each book ordinarily contains 25 gold leaves. There are two sizes of these books: 25 leaves of the smallest only weigh five or six grains, and the same number of the largest nine or ten grains.

It must be observed, that gold is beaten more or less, according to the kind or quality of the work it is intended for; that for the gold wire-drawers to gild their ingots with is left much thicker than that for gilding the frames of pictures, &c. See Gilding.

Gold, *burnished*, that smoothed or polished with a burnisher.

Gold, *mosaic*, that applied in pannels, on proper ground, distributed into squares, lozenges, and other compartments, parts whereof is shadowed to heighten or raise the rest. See Mosaic.

Gold, *shell*, that used by the illuminers, and with which we write gold letters. It is made of the parings of leaf-gold, and even of the leaves themselves, reduced into an impalpable powder, by grinding on a marble with honey. After leaving it to infuse some time in aquafortis, they put it in shells, where it sticks. To use it, they dilute it with gum-water, or soap-water.

Gold, *pure*, that purged by fire of all its impurities, and all alloy. The moderns frequently call it gold of 24 caracts, but in reality there is no such thing as gold so very pure, and there is always wanting at least a quarter of a caract. Gold of 22 caracts has one part of silver, and another of copper; that of 23 caracts has half a part (that is, half a twenty-fourth) of each. See Caract.

Gold, in heraldry, is one of the metals, more usually called by the French name *or*.

GOLDEN number, in chronology, a number showing what year of the moon's cycle any given year is. See Cycle.

From what has been said under Cycle of the moon, it appears that the golden number will not show the true change of the moon for more than 312 years, without being varied. It is to be observed, that the golden number is not so well adapted to the Gregorian as to the Julian calendar; the epact being more certain in the new style, to find which the golden number is of use. See Epact, and Cycle.

Golden rule, in arithmetic, is also called the rule of three, and the rule of proportion. See Arithmetic.

GOLDFINCH. See Fringilla.

GOLDSMITH, or, as some choose to express it, silversmith, an artist who makes vessels, utensils, and ornaments, in gold and silver.

The goldsmith's work is either performed in the mould, or beaten out with the hammer, or other engine. All works that have raised figures are cast in a mould, and afterwards polished and finished: plates or dishes of silver or gold are beaten out from thin flat plates; and tankards, and other vessels of that kind, are formed of plates soldered together, and their mouldings are beaten, not cast. The business of the goldsmith formerly required much more labour than it does at present; for they were obliged to hammer the metal from the ingot to the thinness they wanted: but the flatting-mills now in use reduce metals to the thinness that is required, at a very small expense. The goldsmith is to make his own moulds, and for that reason ought to be a good designer, and have a taste in sculpture; he also ought to know enough of metallurgy to be able to assay mixed metals, and to mix the alloy. See Assaying.

The goldsmiths in London employ several hands under them for the various articles of their trade; such are the jeweller, the snuff-box and toy-maker, the silver turner, the gilder, the burnisher, the chaser, the refiner, and the gold-beater. See Jeweller, &c.

Goldsmiths are superior tradesmen; their wares must be assayed by the wardens of the company of this name in London, and marked: and gold is to be of a certain touch. No goldsmith may take above one shilling the ounce of gold, besides what he has for the fashioning, more than the buyer may be allowed for it at the king's exchange; and here any false metal shall be seized and forfeited to the king. The cities of York, Exeter, Bristol, &c. are places appointed for the assaying wrought plate of goldsmiths; also a duty is granted on silver plate of sixpence an ounce, &c. Plate made by goldsmiths shall be of a particular fineness, on pain of forfeiting 10*l.* and if any parcel of plate sent to the assayers is discovered to be of a coarser alloy than the respective standards, it may be broken, and defaced; and the fees for assaying are particularly limited.

GOMPHIA, a genus of the decandria monogynia class and order. The calyx is five leaved; the corolla five-petalled; berries two; (1 to 5) in a large receptacle. Seed solitary. There are three species, trees of the East and West Indies.

GOMPHRÆNA, *globe amaranth*, a genus of the di-

gynia order, in the pentandria class of plants, and in the natural method ranking under the 54th order, miscellaneæ. The calyx is coloured; the exterior one triphyllous, or diphyllous, with two carinated convenient leaflets; the nectarium cylindrical, with ten teeth; the capsule monospermous. There are nine species, but only one of them is commonly cultivated in our gardens, viz. the globosa, or globe amaranth. It has an upright stalk branching all round, two or three feet high, with oval, lanceolate, and opposite leaves; and every branch and side-shoot terminated by a close globular head of flowers, composed of numerous very small starry florets, closely covered with dry scaly calices placed imbricatim, persistent, and beautifully coloured purple, white, red, or striped and variegated. The florets themselves are so small, and closely covered with the scaly calices, that they scarcely appear. The numerous closely placed scaly coverings being of a dry firm consistence, coloured and glittering, collected into a compact round head, about the size of an ordinary cherry, make a fine appearance. They are annual plants, natives of India, and require artificial heat to raise and forward them to a proper growth, so that they may flower in perfection, and produce ripe seed. They flower from June to November; and if the flowers are gathered when at full growth, and placed out of the sun, they will retain their beauty several months.

GONARCHA, in antiquity, a dial delineated on several surfaces, or planes, some horizontal, others erect, oblique, &c.

GONATOCARPUS, a genus of the tetrandria monogynia class and order. The corolla is four cleft, drupe eight-cornered, one-seeded. There is one species, an annual of Nogasaki.

GONDOLA, a flat boat, very long and narrow, chiefly used at Venice to row on the canals. The word is Italian, gondola. Du Cange derives it from the vulgar Greek κουντιλας, "a bark," or "little ship;" Lancelot deduces it from γονδυ, a term in Athenæus for a sort of vase. The middle-sized gondolas are upwards of thirty feet long and four broad; they always terminate at each end in a very sharp point, which is raised perpendicularly to the full height of a man. The address of the Venetian gondoleers, in passing along their narrow canals, is very remarkable: there are usually two to each gondola, and they row by pushing before them. The fore man rests his oar on the left side of the gondola: the hind man is placed on the stern, that he may see the head over the tilt or covering of the gondola, and rest his oar, which is very long, on the right side of the gondola. Gondola is also the name of a passage-boat of six or eight oars, used in other parts of the coast of Italy.

GONDOLA-SHELL, in natural history. See DOLIUM.

GONHORRHŒA. See SURGERY.

GONIOMETRY, a method of measuring angles, so called by M. de Lagny, who gave several papers, on this method, in the memoirs of the Royal Academy. M. de Lagny's method of goniometry consists in measuring the angle with a pair of compasses, and that without any scale whatever, except an undivided semicircle. Thus, having any angle drawn upon paper, to be measured, produce one of the sides of the angle backwards behind the angular point; then with a pair of fine compasses describe a pretty large semicircle from the angular point as a centre, cutting the sides of the proposed angle, which will intercept a part of the semicircle. Take then this intercepted part very exactly between the points of the compasses, and turn them successively over upon the arc of the semicircle, to find how often it is contained in it, after which there is commonly some remainder: then take this remainder in the compasses, and in like manner find how often it is contained in the last of the integral parts of the first arc, with again some remainder: find in like manner how often this last remainder is contained in the former; and so on continually, till the remainder become too small to be taken and applied as a measure. By this means he abtains a series of quotients, or fractional parts, one of another, which being properly reduced into one fraction, give the ratio of the first arc to the semicircle, or of the proposed angle to two right angles, or 180 degrees, and consequently that angle itself in degrees and minutes.

Thus suppose the angle BAC (Pl. LXIV. Mis. fig. 107.) be proposed to be measured. Produce BA towards *f*; and from the centre A describe the semicircle *a b c f*, in which *a b* is the measure of the proposed angle. Take *ab* in the compasses, and apply it four times on the semicircle, as at *b*, *c*, *d*, and *e*; then take the remainder *fe*, and apply it back upon *ed*, which is but once, viz. at *g*; again take the remainder *gd*, and apply it five times on *ge*, as at *h*, *i*, *k*, *l*, and *m*; lastly, take the remainder *m e*, and it is contained just two times in *m l*. Hence the series of quotients is 4, 1, 5, 2; consequently the fourth or last arc *em* is $\frac{1}{2}$ the third *ml* or *gd*, and therefore the 3d arc *gd* is $\frac{1}{5\frac{1}{2}}$, or $\frac{2}{11}$ of the 2d arc *ef*; and therefore, again this 2d arc *ef* is $\frac{1}{1\frac{2}{11}}$, or $\frac{11}{13}$ of the 1st arc *ab*; and consequently this 1st arc *ab* is $\frac{1}{4\frac{11}{13}}$, or $\frac{13}{63}$ of the whole semicircle *af*. But $\frac{13}{63}$ of 180° are $37\frac{1}{7}$ degrees, or $37°\ 8'\ 34''\frac{2}{7}$, which therefore is the measure of the angle sought. When the operation is nicely performed, this angle may be within two or three minutes of the truth; though M. de Lagny pretends to measure much nearer than that.

GONIUM, a genus of Vermes, of the order infusoria. Worm very simple, flat, angular, invisible to the naked eye. There are five species. The pectoral, quadrangular, pellucid, with 16 spherical molucles, found in pure water; molecules oval, nearly equal in size, set in a quadrangular membrane, like diamonds in a ring, the lower ones a little larger than the rest. See Adams on the Microscope.

GOOD BEHAVIOUR: surety for the good behaviour is the bail or pledge for any person that he shall do or perform such a thing, as surety for the peace is the acknowledging a recognizance or bond to the king, taken by a competent judge of record, for keeping the king's peace. Dalt. c. 116.

A binding to the good behaviour is not by way of punishment; but it is to show, that when a man has broken the good behaviour, he is not to be trusted. 12 Mod. 566.

Justices of peace may chastise rioters, barrators, and other offenders, and also imprison and punish them ac-

cording to law, and by discretion and good advisement; and also bind persons of evil fame to the good behaviour, &c. 34 Ed. III. c. 1.

This statute being penned in such general words, seems in a great measure to have left it to the discretion of justices of the peace, to determine what persons should be bound to their good behaviour; and consequently seems to empower them, not only to bind over those who seem to be notoriously troublesome, and likely to break the peace, as eves-droppers, &c. but also those who are publicly scandalous, or contemners of justice, &c. as haunters of bawdy-houses, or keepers of lewd women in their own houses; common drunkards, or those who sleep in the day and go abroad in the night, or such as keep suspicious company, or such as are generally suspected as robbers; or such as speak contemptuous words of superior magistrates, as justices of peace, mayors, &c. being in the actual execution of their office, or of inferior officers of justice, as constables, &c. being in the actual execution of their office; but it seems that rash, quarrelsome, or unmannerly words, spoken by one private person to another, unless they directly tend to a breach of the peace, are not sufficient cause to bind a man to his good behaviour. 1 Haw. 133.

GOODENIA, a genus of the pentandria monogynia class and order. The corolla is five-cleft; anthers linear; stigma cup-shaped, ciliated; caps. two-celled, two valved. Seeds many, imbricated. There are nine species, shrubs of South Wales.

GOOSE. See ANAS.

GOOSEBERRY, grossularia. See RIBES.

GOOSE-EMBER. See MARGUS.

GOOSE-NECK, in a ship, a piece of iron fixed on the end of the tiller; to which the laniard of the whip-staff, or the wheel-rope comes, for steering the ship.

GOOSE-WING, in the sea-language. When a ship sails before, or with, a quarter-wind on a fresh gale, to make the more haste, they launch out a boom, and sail on the lee-side; and a sail so fitted, is called a goose-wing.

GORDIUS, the *hair-worm*, a genus of insects belonging to the class of vermes intestina. There are several species: 1. The aquaticus, or water hair-worm, is 10 or 12 inches in length, and of about the thickness of a horse-hair; its skin is smooth, and somewhat glossy, without furrows; its colour pale-yellowish white all over, except the head and tail, which are black and glossy. The body is rounded, and very slender in proportion to its length; the mouth is small, and placed horizontally; the jaws are both of the same length, and obtuse at their extremities. This species is common in our fresh waters, more especially in clay, through which it passes as a fish does through the water, and is the author of many springs. It is a variety of this worm that in Guinea, and in some other of the hot countries, gets into the flesh of the natives, and occasions great mischief; with us, though frequent enough in water where people bathe, it never attempts this. 2. The argillaceous, or clay hair-worm, is only a variation of the preceding one in colour, being yellowish at the extremities. It chiefly inhabits the clay; Linnæus calls that its proper element, from its being generally dug out of it. 3. The medinensis, or muscular hair-worm, is all over of a pale yellowish colour. It is a native of both Indies; frequent in the morning dew, whence it enters the naked feet of the slaves, and occasions a disease much known in those countries, and to which children are very liable; it creates the most troublesome itchings, and too often excites a fever and inflammation. It particularly attacks the muscles of the arms and legs, whence it may be drawn out by means of a piece of silk or thread tied round the head; but the greatest caution is necessary in this simple operation, lest the animal, by being strained too much, should break; for if any part remains under the skin, it quickly grows with redoubled vigour, and becomes a cruel, and sometimes fatal enemy to the poor slaves in particular. Baths with infusions of bitter plants, and all vermifuges, destroy it. 4. The marinus, or sea hair-worm, is filiform, twisted spirally and lying flat, about half an inch in length; of a whitish colour, smooth, and scarcely diminishing at the head. It is as great a tormentor of herrings, bleaks, and various other fish, as the gordius medinensis is of man. The fish, when infested with these animals, rise to the surface, and tumble about as if in great agony.

GORDONIA, a genus of the polyandria order, in the monadelphia class of plants. The calyx is simple; the style five-cornered, with the stigma quinquefid; the capsule quinquelocular; the seeds two-fold, with a leafy wing. There are three species. The lasianthus is a tall and very straight tree, with a regular pyramidal head. Its leaves are shaped like those of the common bay, but serrated. It begins to blossom in May, and continues bringing forth its flowers the greatest part of the summer. The flowers are fixed to footstalks, four or five inches long; are monopetalous, divided into five segments, encompassing a tuft of stamina headed with yellow apices; these flowers, in November, are succeeded by a conic capsula, having a divided calyx. The capsula, when ripe, opens and divides into five sections, disclosing many small half-winged seeds. This tree retains its leaves all the year, and grows only in wet places, and usually in water. The wood is somewhat soft; yet Mr. Catesby mentions his having seen some beautiful tables made of it. It grows in Carolina, but not in any of the more northern colonies.

GORGONIA, in natural history, a genus of zoophytes, which formerly were called ceratophytons, and are known in English by the names of sea-fans, sea-feathers, and sea-whips. Linnæus and Dr. Pallas consider them as of a mixed nature in their growth, between animals and vegetables: but Mr. Ellis shows them to be true animals of the polype kind, growing up in a branched form resembling a shrub, and in no part vegetable. They differ from the fresh-water polype in many of the qualities, and particularly in producing from their own substance a hard and solid support, serving many of the purposes of the bone in other animals. This is formed by a concreting juice, thrown out from a peculiar set of longitudinal parallel tubes, running along the internal surface of the fleshy part: in the coats of these tubes are a number of small orifices, through which the osseous liquor exudes, and concreting, forms the layers of that hard part of the annular circles, which some, judging from the consistence rather than the texture, have erroneously denominated wood. The surface of the gorgonia is composed of a kind of scales, so well adapted to each other, as to serve for defence rom external injuries; and the

flesh, or, as some have called it, the bark or cortex, consists of proper muscles and tendons for extending the opening of their cells; for sending forth from thence their polype suckers in search of food, and for drawing them in suddenly, and contracting the sphincter muscles of these starry cells, in order to secure these tender parts from danger; and also of proper secretory ducts, to furnish and deposit the osseous matter that forms the stem and branches as well as the base of the bone. Mr. Ellis affirms, that there are ovaries in these animals, and thinks it very probable that many of them are viviparous. See CORALLINES, and ZOOPHYTES.

GORE, in heraldry, one of the abatements, which, according to Guillim, denotes a coward. It is a figure consisting of two arch lines drawn one from the sinister chief, and the other from the sinister base, both meeting in an acute angle in the middle of the fess point.

GORE, in law, signifies a narrow slip of ground.

GOREING, in the sea-language, sloping. A sail is cut goreing, when it is cut sloping by degrees, and is broader at the clew than at the earing, as all topsails and top-gallant sails are.

GORGE, in fortification, the entrance of the platform of any work. See FORTIFICATION.

In all the outworks, the gorge is the interval betwixt the wings on the side of the great ditch, as the gorge of a ravelin, half-moon, &c. These, it is to be observed, are all destitute of parapets; because if there were any, the besiegers, having taken possession of the work, might use it to defend themselves from the shot of the place; which is the reason that they are only fortified with palisadoes, to prevent a surprise.

The gorge of a bastion is nothing but the prolongation of the curtins from their angle with the flanks, to the centre of the bastion where they meet. When the bastion is flat, the gorge is a right line, which terminates the distance between the two ranks.

GORGED, in heraldry, the bearing of a crown, coronet, or the like, about the neck of a lion, a swan, &c. and in that case it is said, the lion or cygnet is gorged with a ducal coronet, &c.

GORTERIA, a genus of the class and order syngenesia polygamia frustranea class and order. The calyx is intricate; corolla of the ray ligulate; down, woolly; receptacle, naked. There are 13 species, mostly shrubby plants of the Cape.

GOSHAWK. See FALCO.

GOSSAMER, is the name of a fine filmy substance, like cobweb, which is seen to float in the air in clear days in autumn, and is more observable in the stubble-fields, and upon furze and other low bushes. This is probably formed by the flying-spider, which, in traversing the air for food, shoots out these threads from its anus, which are borne down by the dew, &c.

GOSSYPIUM, or cotton; a genus of the polyandria order, in the monadelphia class of plants, and in the natural method ranking under the 37th order, columniferæ. The calyx is double, the exterior one trifid; the capsule quadrilocular; the seeds wrapt in cotton-wool. There are six species, all of them natives of warm climates. 1. The herbaceum, or common herbaceous cotton, has an herbaceous smooth stalk two feet high, branching upwards; five-lobed smooth leaves; and yellow flowers from the ends of the branches, succeeded by roundish capsules full of seed and cotton. 2. The hirsutum, or hairy American cotton, has hairy stalks branching laterally two or three feet high; palmated, three and five-lobed hairy leaves; and yellow flowers, succeeded by large oval pods furnished with seeds and cotton. 3. The barbadense, or Barbadoes shrubby cotton, has a shrubby stalk branching four or five feet high, three-lobed smooth leaves; glandulous underneath; and yellow flowers succeeded by oval pods; containing seeds and cotton. 4. The arboreum, or tree cotton, has an upright woody perennial stalk, branching six or eight feet high; palmated, four or five-lobed smooth leaves, and yellow flowers, succeeded by large pods filled with seeds and cotton. The first three species are annual, but the fourth is perennial both in root and stalk. In warm countries these plants are cultivated in great quantities in the fields for the sake of the cotton they produce; but the first species is most generally cultivated. The pods are sometimes as large as middling-sized apples, closely filled with the cotton surrounding the seed. They are propagated by seeds.

The American islands produce cotton shrubs of various sizes, which rise and grow up without any culture, especially in low and marshy grounds. Their produce is of a pale red, some paler than others, but so short that it cannot be spun. None of this is taken to Europe, though it might be usefully employed in making hats. The little that is picked up serves to make mattrasses and pillows.

The cotton shrub that supplies our manufactures requires a dry and stony soil, and thrives best in grounds that have already been tilled. Not but the plant appears more flourishing in fresh lands than in those which are exhausted; but while it produces more wood, it bears less fruit. A western exposure is fittest for it. The culture of it begins in March and April, and continues during the first spring-rains. Holes are made at seven or eight feet distance from each other, and a few seeds thrown in. When they are grown to the height of five or six inches, all the stems are pulled up, except two or three of the strongest. These are cropped twice before the end of August. This precaution is the more necessary, as the wood bears no fruit till after the second pruning; and if the shrub was suffered to grow more than four feet high, the crop would not be the greater, nor the fruit so easily gathered. The same method is pursued for three years; for so long the shrub may continue, if it cannot conveniently be renewed oftener with the prospect of an advantage that will compensate the trouble. This useful plant will not thrive if great attention is not paid to pluck up the weeds that grow about it. Frequent rains will promote its growth, but they must not be incessant. Dry weather is particularly necessary in the months of March and April, which is the time of gathering the cotton, to prevent it from being discoloured and spotted. When it is all gathered in, the seeds must be picked out from the wool with which they are naturally mixed. This is done by means of a cotton-mill, which is an engine composed of two rods of hard wood, about 18 feet long, 18 lines in

circumference and fluted two lines deep. They are confined at both ends, so as to leave no more distance between them than is necessary for the seed to slip through. At one end is a kind of little millstone, which, being put in motion with the foot, turns the rods in contrary directions. They separate the cotton, and throw out the seed contained in it.

GOUANIA, a genus of the monoecia order, in the polygamia class of plants. The calyx of the hermaphrodite is quinquefid; there is no corolla; there are five antheræ covered with an elastic calyptra or hood; the style trifid; the fruit, inferior to the receptacle of the flower, divisible into three seeds. The male is like the hermaphrodite, but wanting stigma and germen. There is one species, a shrubby plant of St. Domingo.

GOUGE, an instrument or tool used by divers artificers; being a sort of round hollow chisel, for cutting holes, channels, grooves, &c. either in wood or stone.

GOURD. See Cucurbita.

GOUT. See Medicine.

GRACE, *act of*, an act of parliament for a general and free pardon, and for setting at liberty insolvent debtors.

Grace, *days of*, in commerce. See Bills of Exchange.

GRACULA, the grakle, in ornithology, a genus belonging to the order of picæ. The bill is convex, cultrated, and bare at the point; the tongue is not cloven, but is fleshy and sharp; it has three toes before and one behind. 1. The religiosa, lesser grakle, or Indian stare, is about the size of a blackbird; the bill an inch and a half long, and of an orange colour. The general colour of the plumage is black, glossed with violet, purple, and green, in different reflections of light; on the quills is a bar of white; the feathers and legs are an orange-yellow, and the claws of a pale brown. This species, which is found in several parts of the East Indies, in the Isle of Hainan, and almost every isle beyond the Ganges, is remarkable for whistling, singing, and talking well, much better than any of the parrot genus, and in particular very distinct. Its food is of the vegetable kind. Those kept in this climate are observed to be very fond of cherries and grapes; if cherries are offered to one, and it does not immediately get them, it cries and whines like a young child, till it has obtained its desire. It is a very tame and familiar bird. 2. The barita, or boat-tailed grakle, is about the size of a cuckow. The bill is sharp, black, and an inch and a half in length; the general colour of the plumage is black, with a gloss of purple, especially on the upper parts; the legs and claws are black, the latter hooked. There is a singularity in the folding up of the tail feathers, which, instead of forming a plain surface at top, sink into a hollow like a deep gutter. It always carries its tail expanded when on the ground, folding it up in the above singular manner only when perched or flying. It inhabits Jamaica; and it feeds on maize, on beetles and other insects, as well as on the fruit of the banana. It is likewise common in North America, keeping company with the flocks of the maize-thieves, and red-winged oriole. These breed in the swamps, and migrate in September, after which none are seen. 3. The quiscula, purple jackdaw, or Barbadoes blackbird, is about the size of a blackbird: the male bird is black, but most beautifully and richly glossed with purple; especially on the head and neck. The female is wholly of a brown colour, deepest on the wings and tail. This species inhabits Carolina, Mexico, and other parts of North America, also Jamaica. These birds for the most part feed on maize, whence the name of maize-thieves has been given them; but this is not their only food, for they are known also to feed on many other things. In spring, soon after the maize-seed is put into the ground, they scratch it up again; and as soon as the leaf comes out, they take it up with their bills, root and all; but when it is ripe they do still more damage, for at that time they come in troops of thousands, and are so bold, that if disturbed in one part of the field they only go to another. In New Jersey and Pennsylvania three pence per dozen was once given for the dead bodies, and by means of the premium they were nearly extirpated in 1750; when the persecution of them was abated on account of the increase of worms which had taken place in the meadows, and which in the preceding year had left so little hay in New England as to occasion an importation from other parts. The grakles were therefore again tolerated, as it was observed that they fed on these worms till the maize was ripe. These birds build in trees. They are said to pass the winter in swamps which are quite overgrown with wood, thence only appearing in mild weather; and after the maize is got in, are content to feed on other things, as the aquatic tare-grass, and if pressed by hunger, buck-wheat and oats, &c.: they are said also to destroy that pernicious insect the bruchus pisi. Their note is pretty and agreeable, but their flesh is not good to eat. 4. The cristatella, or Chinese starling, is a little bigger than a blackbird. The bill is yellow or orange, and the general colour of the plumage blackish with a tinge of blue; the legs are of a dull yellow. These birds, which are said to talk and whistle very well, are common in China, where they are very much esteemed, and the figures of them are seen frequently in Chinese paintings. Their food is rice, insects, worms, and such-like. They are seldom taken to England alive, requiring the greatest care in the passage. There are eight other species of gracula.

GRADUATION, in mathematics, the act of dividing any thing into degrees, or equal parts.

GRAFTING, or *graffing*, in gardening, is the insertion of a scion into a stock or stem raised for the purpose, and is necessary to the ensuring of good fruit; *i. e.* to have the same (or at least with little difference) produced on the new tree, as that of the old one whence the graft was taken: it is sometimes performed on the branches of trees, and may be on the roots, a piece being raised out of the ground for the purpose.

If the seeds of fruit were left to grow up to trees without grafting, they would produce a different kind from that they came from; by chance a better, but most commonly a worse. The varieties of fruit we have, were obviously obtained from seedling stocks, without grafting.

Grafting is like planting upon a plant, for though there is a union of the parts, there is in fact little other communication than a root has with the ground. The scion, or bud, draws nourishment from the stock, but no other than is properly adapted to its own peculiar vessels, and which it alters so as to become exclusively its own.

The art of grafting is a very curious discovery, and though it requires some ingenuity to perform it, a few trials may make it familiar, and it will prove an agreeable source of amusement and satisfaction. By being able to graft, young trees may be always at hand for replacing old, or unsuccessful ones; and the pleasure of obliging a friend from our stock in this way, is peculiarly gratifying.

Skill in this ingenious art is clearly best obtained by seeing the work performed; and at first trial, to have an adept at the elbow, would be a great advantage. There are few gardeners (even by profession), however, that practise this work, owing to the great number of nurserymen ready to supply trees. But though they raise fine trees, much disappointment has often happened in dealing with them (particularly in the sort); which might be avoided, by a man's being able to raise good trees for himself. Directions precisely descriptive of the business of grafting, are therefore here attempted, and if once understood, trials should be made without minding the discouragement of a few failures; for practice will make perfect.

Proper stocks being ready, and scions or buds procured, there will be wanting a good sharp narrow-bladed penknife, and a sharp smooth-edged pruning-knife, with some well-wrought loam or clay, and some good new bass, or strong yarn. The clay should be made up as mortar, mixed with short hair, or fine chopt hay, with a little cow-dung, and prepared a day or two beforehand; or if longer the better, being beaten up afresh with a little water every day.

The first thing to be done is, to cut off the head of the stock at the proper height, and in a fair part of the bark, making a smooth flat top; if the stock is too strong for the knife, and a saw is used, it must be smoothed with the knife after. The most proper size for stocks, is from half an inch to an inch diameter: a little more or less, however, may do. When a stock is too little, the scion is apt to overgrow it, and when too big, the scion does not so well, or so soon, cover the stock, as might be wished; yet stocks of any size can be used by one mode of grafting or other.

Dwarf trees are to be grafted within six inches of the ground, and standards as high as the stock will well bear, considering whether they are to be half or full standards; the former at about three or four feet, the latter at five or six. But trees designed for standards, may be grafted or inoculated at a lower height, the graft being trained to the desired length, by keeping it to a single stem.

The scions should be healthy and strong (not however of a soft, sappy, luxuriant growth), and taken from the outsides of fruitful trees, where the juices of the wood have been properly digested by sun and air; they should be taken (if it may be) from trees just in their prime, or at full bearing, and not before. Let them be cut two or three weeks sooner than wanted, and if kept longer they may not hurt, for they had better be cut a little too soon than too late, at full length, without any side shoots.

Let the scions of pears, plums, and cherries, be cut from the middle to the end of January, and at farthest not beyond the middle of February; the season must, however, somewhat govern. Keep them all over in dry mould, close under a south wall, or some shelter, covering them with straw in wet or severe weather. Some preserve them in a cool room, where they will do without mould, but it would be better to set them upon end in a garden-pot, half their length with mould or sand, nearly dry.

Scions cut early are prevented from getting too forward in bud: for if the buds begin to start, and look white, they seldom take. By having them as long as they may be kept before used, the sap of the stock gets in forwardness; for it must first begin to stir, and so be ready to push itself quickly into the scion (now somewhat exhausted), to form an union with it.

The middle of scions is fittest for the purpose; but do not cut off the tops till they are brought out to graft, for they keep best in length. If scions are to be transported to any distance, let their ends be stuck two or three inches in clay, and so matted round in a bundle; or, if wrapped round with a fine hay-rope, and smeared over with cow-dung, clay, or a strong earth, they will not soon wither.

Some gardeners say, scions should be only of the last year's growth, and others, that the wood of the year before is best; but it is so far a matter of indifference that they will take much older, though perhaps, not so certainly. As a medium, if a little of the former year's wood is cut with a scion of the last, and this older wood used for the part grafted, it will be found to answer, in covering the stock sooner; though it must be acknowledged, that all new wood is the common practice of those who raise trees for sale; which circumstance is ordinarily, a presumptive proof of right. If wood, however, of a year's growth is not strong enough, then, at least, some of the old wood ought to be cut with it; and the bigger the stock is, the more this practice commends itself, as the barks will be somewhat more equal in thickness.

Proceeding to graft, take off a little of the lower end of the scion first, and then cut it in length, so as to have three or four eyes to appear above the claying; two eyes will be sufficient for a standard, but four are better for a dwarf that is to be trained. In cutting scions into lengths, let the top eye be just in front or just behind, but rather the former. Use not (except upon necessity) the upper part of a scion, as the wood is too raw for the purpose, and will be shrivelled; yet strong scions (properly inserted) seldom miss through drought; indeed they will take sooner than if quite fresh cut and full of sap.

The time for grafting is usually from mid-February to mid-March; but in a forward season sooner, and in a backward one sometimes later.

Cleft-grafting has been the most common method of progation, and though it is not the neatest, yet it is a certain and easy way to young practitioners. The stocks for this mode of grafting should be strong, about three quarters of an inch diameter, or more; but it may be used with very young stocks, having scions of like thickness.

Cut off the head as before directed, so as to have (on the sunny side) a smooth part in the stock, where the scion is to be placed, and cutting a part of the stock off slopewise, opposite to this place, leave the top or the crown of the stock, about half an inch wide.

Then cleave the stock with a strong knife, or thin sharp chisel, about two inches deep, as near the middle as possible, so as not to divide the pith, and if any roughness appears in the slit, smooth it off with a penknife;

but something of the wedge kind must be put into the slit to keep it open to receive the scion, leaving proper room to put it in. Cut the scion on each side to the form of a wedge at bottom, an inch or more long, making that side which is to be placed inwards in the stock, thinner by about one-third. Put the scion in, so that its bark and that of the stock may be level; and consequently that the two barks may unite and run into each other; for on this one principle depends the whole art of grafting. If the bark of the stock is thick, let the bark of the scion sink in a trifle, as the current of sap that unites them, runs betwixt the bark and wood. The scion being placed, take the wedge out that kept the stock open; yet if the stock is so strong as to pinch the scion too hard, ease it by a little bit of dry wood to be left in the cleft; so, however, as not to loosen the graft, which must be held firmly: or if the stock is very strong, the wedge of the scion may be nearly of equal thickness, inside and out, which cases the barked part.

The graft must be nicely whipped round with wet bass pulled tight, and the whole clayed over to an inch above and half an inch below, smoothing it off taper, with a trowel or knife dipped in water. And as this is done with a view to keep out wet, sun, and air, if the clay falls off or cracks, it must be immediately repaired, till the season comes to take off the bandage, which is about Midsummer, or rather sooner; yet at this time some clay should be still kept on the top, to secure the cleft from wet, and so continued till the cleft is grown up.

If it is desired to put in two scions, to form a tree for the wall, or espallier, there should be two clefts parallel to one another, one on each side the pith. Some put in two scions, merely in case one should miss; but it is not advisable. It need hardly be observed, that in this case the crown must be left whole.

Whip-grafting has the advantage of cleft-grafting in neatness, and not requiring the stocks to be so old by a year or two, as very small ones will do in this way; for the stock is directly covered by the scion, and it takes with certainty if properly performed. Scions suitable to proper stocks cannot however always be had. Stock and scion are to be both of a size; or nearly so is better, the stock having the advantage in bigness; for thus it is not so likely to be overgrown, as it happens when the scion is of a more free nature. When the stock is overgrown by the scion, it will give it some opportunity to thicken, by slitting the bark through downwards, in two or three places. This circumstance is not, however, material in dwarf trees.

Having cut the head of the stock off, and the scion to its proper length, slope the lower end of the scion about an inch and a half, and to a point; then cut the stock to answer it (the cut of the stock, however, may be a trifle wider and longer) bark against bark, and tie them together exactly to their place, and clay it. But for the greater certainty of keeping a scion to the part, cut it so as to leave a small shoulder at the top of the slope, and the stock so as to leave a narrow bit of its crown to answer it, and to hold it.

There is a sort of whip-grafting that has been denominated slicing, or packing, which differs only from that just described, in this: that the stock is of any size; and this is performed by cutting the scion to a face, as before, and then taking off a slice from the (beheaded) stock, choosing a gibbous part of it so as exactly to correspond with the cut surface of the scion, taking care to fit them so that the scion may stand erect (or nearly) when clapped to. Shouldering is commonly practised also in this way.

Grafting in the bark, or *crown-grafting*, is perhaps as good a way as any, both for ease of operation and certainty of success; but it will hardly suit any other fruit than apples or pears, as other scions will be past use (most likely) before the bark of the stocks will peel, as the time for this business is towards the end of March, or beginning of April.

The head being cut off, make a straight slit down and through the bark from the top, at the place destined for the graft, which should be rather southerly or westerly. This score down the bark should be nearly as long as the slope cut of the scion, which may be one and a half or two inches. Loosen the bark a little at the top of the score, and then with some smooth instrument of dry hard wood, ivory, bone, or silver, rather than iron or steel, open the bark sufficiently to receive the scion, by pushing the instrument down a trifle below the bottom of the slit. This instrument should be thin, tapered and rounded towards the point, to suit the shape of the scion's face; one side of it flat, and the other a little convex, the flat side being applied to the wood of the stock; let it be rather narrower than the scion, that it may not loosen the bark too wide.

Cut a bit of the bark of the scion smooth off at the bottom that it may not turn up in pushing down. It will be proper to cut the scion with a small shoulder, to rest upon the stock. And because when the scion is in, it will bear the bark up hollow from the stock, score the bark on each side the scion, so that it may fall close to the stock, and to the edges of the scion. Bind and clay neatly. In this way of grafting there is a sort of agreement between the scion and stock necessary; the scion not being too big, or the stock too small, to prevent a proper bedding. If more than one scion is not put in, the stock on the opposite side to the scion should be sloped up about two inches in length, to half its thickness.

This way of grafting is used most properly with strong stocks; and sometimes is applied to large branches, and even trunks of old trees, to change the sorts or renew the wood. In proportion to the largeness of which, from two to five or six scions are put in, and sometimes of different sorts; and if the stock is large, the more the better, as it heals over the sooner, and as they insure the life of the stock, by receiving and carrying off the sap; in which respect a single branch of the head of an old stock may be left on, for the sap to pass off by when it begins to stir.

Side-grafting is done in the bark, much like inoculation, a scion being inserted instead of a bud; but remember, there must be a fluent sap first, *i. e.* the bark must part readily from the wood, before this mode of grafting is attempted. The head of the stock is not to be cut off, only thinned a little if it is large, and the side shoots taken away. The bark of the stock, where the insertion of the scion is to be, must be cut through in the form of the letter T, as wide and as long as is sufficient to receive the scion, cut as before, with a slope face of at least an inch long, taking advantage, (if it may be) of a part

of the stock that is a little gibbous. Let the bark of the stock be neatly raised to receive it, but yet no more than necessary; a little bit of the bark may be sliced off the part that is over the cross cut, to receive the scion the better.

Approach-grafting, or *inarching*, is performed in April or May, when the stock we would graft, and the tree we would propagate, grow so near together, as to be conveniently in contact, and the nearer the graft and the stock are of a size the better. This mode of propagation is esteemed the surest of all; and in truth, some things cannot be so well propagated any other way. It is a method that is, or can be, seldom used for common fruit-trees: but if any one wishes to try the experiment, the stock or stocks must be planted at least a year before, first making the soil good, as it may need it, being so near another tree, for it of course must be close.

Plants in pots or tubs being easily brought together, are frequently propagated this way; so that inarching is used much in green-houses and hot-houses for various things, as oranges, lemons, pomegranates, jasmines, and vines sometimes; oranges and lemons thus treated in May will be united by August.

The method of inarching is, bend the best-situated young branch of the tree or shrub to be propagated, to the stock to be grafted, and having determined on the part at which most conveniently to fix the shoot, cut the bark of that part of the shoot off, with nearly half the wood (not to touch the pith) to the length of about three inches for a strong branch, or less for a weaker. Then cut exactly so much of the bark and branch of the stock off, as will receive the cut part of the branch or shoot, so as to bring bark and bark in contact in every part; and if the contrivance of lipping is used, it will secure them better together. Bind and clay, and if in open ground, fix a stake to tie the work so that the wind may have no power over it; a tie also to a neat stick may be proper for those inarched in pots, &c.

Budding, or *inoculation*, though here last mentioned, is the most considerable mode of propagation. Apricots, peaches, and nectarines, are always propagated this way, and plums and cherries may be. Pears are sometimes budded, and apples have been, but the success is uncertain. Not only fruit, but forest, and ornamental trees and shrubs are inoculated. The branches also of trees as well as stems are sometimes budded, which is best done on two-years wood, though it may be on both younger and older.

Inoculation begins as soon as good shoots with good eyes, of the present year can be had, so that the season may be reckoned from mid-June to mid-August; but about old Midsummer, or rather after, is the usual and best time for the work; it should be done in a morning or evening (the latter rather best), except the day is cloudy, when any part of it will do.

Apricots being first ready, the budding season begins with them. The stocks to be used are those of the plum (raised from stones or suckers) when half an inch thick, a little under or over, and the operation is to take place from four to eight inches from the ground.

Peaches and nectarines are propagated on the same sort of stocks; but if the plum stock is first budded with an apricot (very low), and when of proper size budded with a peach, and especially a nectarine, the advantage is reckoned that it takes best so, and comes to a better bearing, producing an improved fruit, and particularly the red Roman nectarine. Apricots may be expected to be less luxuriant by double-budding, in which case the first bud should be of the Brussels sort.

Plums and cherries may be inoculated on sucker stocks of any kind; yet, if a tree is required, (as for standards), stocks raised from stones are best; *i. e.* plums on plums, and cherries on cherries, though they will take upon each other.

Pears, if for standards, should be inoculated on pear stocks, and on those raised from seed, rather than suckers; but if for dwarfs, quince stocks may be best used, to keep the trees from growing off too fast, and so getting soon too big for their allotted space; white-thorn stocks are sometimes used with the same view, but the fruit gets stony. Stocks for budding dwarfs should be three years old; but for standards four or more.

Though the longer inoculation is deferred, the riper the shoots will be for furnishing buds; yet there is this advantage in beginning as early as may be, that if the budding appears not to have taken, the work may be done again before the season is out. Or, to ensure success, two buds may be inserted in the same stock (but not in a direction under one another), and if both fail this year, the stocks may do again the next, as the heads in grafting by inoculation are not to be cut off till the spring following, because the inserted buds do not push off till then.

Let the scions to procure buds for inoculation, be taken only from the outside branches of healthy and fruitful trees. If early budding is attempted, it will be proper to cut off some spare shoot (not fit for the purpose) to try first whether the bark will yet readily part from the wood.

The season being right, and the scions at hand, have a sharp narrow-bladed knife, and neat tough wet bass. Keep the buds, as much as may be, from sun and wind: they must not be taken from the upper part of the scions, as the bark and buds there are too raw. If scions or buds are brought from any distance, they should be conveyed in damp moss or grass, and never kept above a day and night, but the sooner they are used the better.

Before the buds are prepared, get the stock ready to receive them, by taking off lateral shoots, leaving an uncut single stem. At the part fixed on for the inoculation (which should be smooth, and rather on the north side) cut the bark through to the wood in form thus, T, the cross and the down slit being of the length necessary to take in the bud, which may be cut with from one to two inches of bark; putting the point of a knife (or some instrument rather not of iron or steel) into the top of the down cut of the stock, raise the bark all the way to the bottom, so that it will just receive the bud easily. There are knives made on purpose for budding, with flat ivory hafts.

To procure proper buds, put your knife in (suppose) about three-fourths of an inch above the eye, and with a slope downwards cut the scion half through, then do it at the same distance below the eye, and sloping it upwards cut up the middle of the wood, till the knife meets the upper incision, so the eye, or bud, will be directly in the middle.

The next step is, to separate the wood from the bark, which is to be done thus: with your nail, or the point of a knife, loosen the bark at the top, and strip it from the wood; or rather with a swan or large goose quill, made in the form of an apple-scoop (having a regular smooth edge) push it down between the bark and wood, pressing it against the wood.

Examine the inside of the bark, and if there is a cavity just behind the eye or bud, it is good for nothing, and another must be procured; for the cavity shows, that the root of the bud is with the wood, instead of being with the bark.

The leaf that grows by the eye is to be cut down to near its footstalk, so as to leave only a little bit of it to hold the bud by, while inserting it in the stock.

See that the bark of the stock is loosened a proper length and breadth, and if, when the bud is put in, it should prove a little too long, cut the spare part off; so that the top of the bud being squared, falls in straight with the cross cut of the stock. Thus fixed, bind it moderately tight in its place with the wet bass, beginning at the bottom, and passing by the bud, go on till the top, or rather above it. Care must be taken that the bud is not hurt, and it is to be left only just starting out between the bass.

If the buds have taken, it will be seen in about three weeks or a month, by their appearing fresh and plump. As often as any shoots appear before the budding, cut them off, and also some of the shoots above, if there are many of them: for it is not proper that an inoculated stock should have a large head. In a month loosen the bandage, by taking it off, and putting it on gently again for another month.

In March, cut the head of the stock off with a keen knife, close behind the budding, in a sloping direction; some leave three or four inches of the stock above the bud till the following spring, and it will serve to tie the new shoot to, in order to keep it to a proper erect direction. Suffer no shoots from the stock, but rub the buds off as soon as they appear. It may be of use to shade inoculated buds a few days by a leaf, or a bit of paper.

GRAIN, a small weight, the twentieth part of a scruple in apothecaries' weight, and the twenty-fourth of a pennyweight troy. A grain weight of gold bullion is worth about two-pence, and that of silver about half a farthing.

GRAIN also denotes the component particles of stones and metals, the veins of wood, &c. Hence cross-grained, or against the grain, is contrary to the fibres of wood, &c.

GRAINING-BOARD, among curriers, an instrument called also a pummel, used to give a grain to their leather.

GRAMMAR, the art of speaking and writing any language with propriety. It is usually divided into four parts, orthography, etymology, syntax, and prosody.

GRALLÆ, in ornithology, is an order of birds, in the Linnean system, which have a beak a little cylindric, rather blunt, and bare of feathers at the base. The tongue is entire and fleshy, pointed at the end, and beset with bristles. The legs are without feathers, above the knees. This order includes 20 genera, viz. the phænicopterus, platalea, palamedea, mycteria, tantalus, ardea, corrira, recurvirostra, scolopax, tringa, fulica, parra, vaginalis, psophia, cancroma, rallus, scopus, glareola, hæmatopus, and charadrius.

GRANADIER, a soldier armed with a sword, a firelock, a bayonet, and a pouch full of hand-granadoes. They wear high caps, are generally the tallest and briskest fellows, and are always the first upon all attacks. Every battalion of foot has generally a company of grenadiers belonging to it, or else four or five grenadiers belong to each company of the battalion; which, on occasion, are drawn out, and form a company of themselves. These always take the right of the battalion.

GRANADO, a hollow ball or shell, of iron or other metal, about two inches and a half in diameter; which being filled with fine powder, is set on fire by means of a small fusee fastened to the touch-hole, made of the same composition as that of a bomb; as soon as the fire enters the shell, it bursts into many pieces, much to the damage of all that stand near.

GRANARY. See HUSBANDRY.

GRANATITE, a stone found in Galicia in Spain, Brittany in France, and at St. Gothard. It is always crystallised in a very peculiar form; two six-sided prisms intersect each other, either at right angles or obliquely. Hence the name cross-stone, by which it was known in France and Spain. Mr. Hauy has proved, in a very ingenious manner, that the primitive form of the granatite is a rectangular prism, whose bases are rhombs, with angles of $129\frac{2}{10}$ and $50\frac{2}{10}$; and that the height of the prism is to the greater diagonal of a rhomb as 1 to 6; and that its integrant molecules are triangular prisms, similar to what would be obtained by cutting the primitive crystal in two, by a plane passing vertically through the shorter diagonal of the rhomboidal base. From this structure he has demonstrated the law of the formation of the cruciform varieties. The colour of granatite is greyish or reddish brown. Specific gravity 3.2861. Usually opaque. Glassy or greasy. Infusible before the blowpipe. Two specimens, analysed by Vauquelin, gave the following constituents:

From Brittany,
44.00 alumina
33.00 silica
13.00 oxide of iron
3.84 lime
1.00 oxide of manganese.

94.84

From St. Gothard,
47.06 alumina
30.59 silica
15.30 oxide of iron
3.00 lime

95.95

GRAND DAYS, are those days in the several terms, which are solemnly kept in the inns of the court of chancery, viz. Candlemas-day, Ascension-day, St. John the Baptist, and all Saint's-day.

GRAND JURY, is the jury which find bills of indictment before justices of peace and gaol-delivery, or of

oyer and terminer, &c. against any offenders that may be tried for the fact. See JURY.

GRANITE, a genus of stones of the order of petræ, belonging to the class of saxa. The principal constituent parts of this stone are feltspar or rhombic quartz, mica, and quartz. These ingredients constitute the hardest sort of granite, and that most anciently known. That into which schoerl enters is more subject to decomposition. They never have any particular texture or regular form, but consist of enormous shapeless masses extremely hard. In the finer granites the quartz is transparent; in others generally white or grey, violet, or brown. The feltspar is generally the most copious ingredient, and of a white, yellow, red, black, or brown colour. The mica is also grey, brown, yellow, green, red, violet, or black; and commonly the least copious. The schoerl is generally black, and abounds in the granites that contain it. Hence the colour of the granites depends principally on that of the spar or schoerl. The red granites consist commonly of white quartz, red feltspar, and grey mica; the grey ones of white quartz grey or violet feltspar, and black mica. The black granites commonly contain schoerl instead of feltspar; and the green usually contain green quartz.

On exposing granite to the flame of a blowpipe, the component ingredients separate from one another. Mr. Gerhard having melted some in a crucible, found the feltspar run into a transparent glass; below it the mica lay in form of a black slag, the quartz remaining unaltered. It melted somewhat better when all the three were powdered and mixed together; though even then the quartz was still discernible by a magnifying-glass. Hence we may explain the reason why grains of a white colour are sometimes found in volcanic lavas. The mixture of mica prevents the silex or quartz from splitting or cracking; and hence its infusibility and use in furnace-building.

Granites are seldom slated or laminated. In those which are of a close texture, the quartz and schoerl predominate. They take a good polish; for which reason the Egyptians formerly, and Italians still work them into larger pieces of ornamental architecture, for which they are extremely fit, as not being liable to decay in the air. Farber, in his letters from Italy, mentions a kind of stone named granitone, composed of feltspar and mica: a substance of this kind, which moulders in the air, is found in Finland; which is said to contain nitre, and sometimes common salt. In that country it is called rapakiri. Wallerius describes 18 species of granites, besides many others akin to this genus. Those particularly in use are,

1. The hard white granite, with black spots, commonly called moor-stone. This is a very valuable kind, consisting of a beautiful congeries of very variously constructed and differently coloured particles, not diffused among or running into one another, but each pure and distinct, though firmly adhering to which ever of the others it comes in contact with, and forming a very firm mass. It is much used in London for the steps of public buildings, and other occasions where great strength and hardness are required.

2. The hard red granite variegated with black and white, are common in Egypt and Arabia.

3. The pale-whitish granite, variegated with black and yellow. This is sometimes found in strata, but more frequently in loose nodules, and is used for paving the streets.

Some of these kinds of stones are found in almost every country, and in many places they are found of immense size. The largest mass of this kind in the known world, lying as an unconnected stone, is found near the Cape of Good Hope in Africa, and of which we have the following description in the Philosoph. Transact. vol. 68, given by Mr. Anderson, in a letter to sir John Pringle: "The stone is so remarkable, that it is called by the people here, the tower of Babel, and by some the pearl diamond. It either takes the last name from a place near which it is situated, or it gives name to the tract of cultivated land called the Pearl. It lies upon the top of a ridge of low hills, beyond a large plain, at the distance of about thirty miles from the Cape Town; beyond which, at a little distance, is a range of hills of a much greater height. It is of an oblong shape, and lies north and south. The south end is highest: the east and west sides are steep and high; but the top is rounded, and slopes away gradually to the north end, so that you can ascend it that way, and enjoy a most extensive prospect of the whole country. I could not precisely determine its circumference, but it took us about half an hour to walk round it; and by making every allowance for the rugged way, and stopping a little, I think the most moderate computation must make it exceed half a mile. The same difficulty occurred with respect to knowing its height; but I think that at the south end it is nearly equal to half its length; or, were I to compare it to an object you are acquainted with, I should say it equalled the dome of St. Paul's church." He adds, "I am uncertain whether it ought to be considered as the top of the hill, or a detached stone, because there is no positive proof of either, unless we were to dig about its base." A part of this stone being examined by sir William Hamilton, he determined it to be a granite, and of the same nature with the tops of some of the Alps; and supposes both of them to have been elevated by volcanic explosions.

GRANITELLO, a genus of stones of the order petræ, belonging to the class of saxa. There are two species,

1. That composed of distinct particles, found in several of the mountainous parts of Sweden. In some of these there is a predominance of quartzose particles, in others of micaceous; in which last case the stone is slaty, and easily split.

2. Granitello composed of convoluted particles. This is met with of different colours, as whitish-grey, greenish, and reddish. Both these kinds of stone are used in building furnaces, on account of the powerful resistance they make to the fire; but the latter is preferable to the other, on account of its containing a little of a refractory clayish substance. It is likewise of great use in mills, where the fellow is a coarse sandstone.

GRANT, in law, a conveyance in writing of such things as cannot pass or be conveyed by word only; such are rents, reversions, services, advowsons in gross, tithes, &c.

The person making such a conveyance is called the grantor, and he to whom the grant is made the grantee.

A grant has usually the words *give and grant*, &c. which in a deed of what lies in grant, will amount either to a gift, grant, feoffment, or release, &c. and accordingly may be pleaded: though to every good grant it is requisite that there be a grantor, or person able to give; a grantee, capable of the thing granted; something granted, as grantable; that it be done in the manner the law requires; and that there be an agreement to, and an acceptance of, the grant by him to whom made, &c.

When persons non sanæ memoriæ make grants, they may be good as to themselves, though voidable by their heirs, &c. and notwithstanding infants and feme-coverts are prohibited by law to be grantors, yet they may be grantees: however an infant, when at his full age, may disagree to his grant, and the husband to that made to his wife. All grants are expounded according to the substance of the deed in a reasonable sense, and agreeable to the intent of the parties. In case a person grants a rent-charge out of land, and he has then nothing in the same, admitting he afterwards purchases the land, nevertheless the grant is void. And the law does not allow of grants of titles only, or imperfect interest, or of things that are merely future. Likewise grants may be void on account of uncertainty, impossibility, being against the law, &c.

Grant *of the king* is good for himself and his successors, though they are not named therein; but the king may not grant away an estate-tail in the crown.

A grant tending to a monopoly cannot be made by the king, to the detriment of the interest and liberty of the subject; neither can the king make a grant non obstante any statute, made or to be made; for if he does, any subsequent statute prohibiting what is granted will be a revocation of the grant: yet there may be a non obstante to a former grant made by the king, where he has been deceived in such grant, as where it contains more than what was intended to be granted, or there is any deceit in the consideration, &c. by which the first grant becomes void.

GRANULATION. See Chemistry.

GRAPE. See Vitis.

Grape-shot, in artillery, is a combination of small shot, put into a thick canvas bag, and corded strongly together, so as to form a kind of cylinder, whose diameter is equal to that of the ball adapted to the cannon. The number of shot in a grape varies according to the service, or size of the guns: in sea-service nine is always the number; but by land it is increased to any number or size, from an ounce and a quarter in weight to three or four pounds. In the sea-service the bottoms and pins are made of iron, whereas those used by land are of wood.

GRAPHIC, *gold ore*. See Tellurium.

GRAPHITES, in mineralogy, a mineral consisting principally of carbon with a little iron, and generally a little silica or alumina; when pure it burns with a reddish flame, emitting beautiful sparks, and a smell of sulphur, and leaving a little residuum. Its colour is dark iron-grey, or brownish black; when cut, blueish grey. Opaque: structure slaty. Texture fine-grained. Brittle. Specific gravity from 1.987 to 2.089; after being soaked in water 2.15; after being heated 2.3. Feels somewhat greasy, stains the fingers, and marks strongly. In modern chemistry it is denominated carburet of iron; and one of the species is plumbago; the use of which, when manufactured into pencils, is known to every one. When pure it consists of,

90 carbon
10 iron
——
100.

GRAPHOMETER, a mathematical instrument, otherwise called a semicircle, the use of which is to observe any angle, whose vertex is at the centre of the instrument in any plane (though it is most commonly horizontal, or nearly so), and to find how many degrees it contains.

The graphometer (Pl. LXIV. Mis. fig. 108) is a graduated semicircle ABC, made of wood, brass, or the like, and so fixed on a fulcrum GH, by means of a brass ball and socket, that it easily turns about, and retains any situation. It has two sights fixed on its diameter AC, and at the centre there are commonly a magnetical needle and compass in a box. There is likewise a moveable ruler or index, ED, with two sights P, P; which turns round the centre, and retains any situation given it.

To measure by this instrument any angle ACB (fig. 109), in any plane, and comprehended between the right lines AC and BC, drawn from two points A and B, to the place of station C. Let the graphometer be placed at C, supported by its fulcrum; and let the immoveable sights on the diameter of the instrument DE, be directed towards the point A; and likewise while the instrument remains immoveable, let the sights of the ruler FG, which is moveable about the centre C, be directed to the point B. Now it is evident that the moveable ruler cuts off an arch DG, which is the measure of the angle ACB, sought. Moreover, by the same method, the inclination of DE, or FG, may be observed with the meridian line, which is pointed out by the magnetic needle inclosed in the box, and moveable about the centre of the instrument.

GRAPNELS, a sort of anchors with four flooks, serving for boats to ride by.

There is also a kind called fire and chain-grapnels, made with four-barbed claws instead of flooks, and used to catch hold of the enemies' rigging, or any other part, in order for boarding them. See Plate LXIV. Miscel. fig. 110.

GRASS. See Botany. For the culture of the different sorts of grass, see Husbandry.

GRASSHOPPER, in zoology. See Gryllus.

GRATINGS, in a ship, a kind of lattice-work formed of ledges and battens, the square holes of which being three or four inches wide, are for the current footing of men over hatchways, to give air below, and vent for the smoke in an engagement.

GRATIOLA, *hedge-hyssop*, a genus of the monogynia order, in the diandria class of plants. The corolla is irregular; there are two barren stamina; the capsule is bilocular; the calyx has seven leaves, with the two exterior ones patulous. There are 12 species; the most remarkable of which is the officinalis, or common hedge-hyssop. This grows naturally in the Alps and other mountainous parts of Europe. It has a thick, fleshy,

fibrous, creeping root, which propagates very much, when planted in a proper soil and situation. From this arise several upright square stalks; with narrow spear-shaped leaves, placed opposite. The flowers are produced on the side of the stalks at each joint; they are shaped like those of the fox-glove, but are small, and of a pale-yellowish colour. This herb has an emetic and purgative virtue; to answer which intentions it was formerly used by the common people in England, but was never much prescribed by the physicians, and at last fell totally into disuse. Of late, however, it has been the subject of a dissertation by Dr. James Kostrzewski, of Warsaw, in Poland, who gives some remarkable accounts of its effects in mania and obstinate venereal cases. It was given in powder, or in extract, to the quantity of half a drachm of the first, and a whole drachm of the second, at each dose.

GRAVE, in music, is applied to a sound which is of a low or deep tone.

GRAVEL, in natural history and gardening, a congeries of pebbles, which, mixed with a stiff loam, makes lasting and elegant walks; an ornament peculiar to our gardens, and which gives them the advantage over those of all other nations.

GRAVEL. See MEDICINE.

GRAVIMETER, the name given by M. Guyton to an instrument for measuring specific gravities: he adopts this name rather than either areometer or hydrometer, because these latter terms are grounded upon the supposition that a fluid is always the thing weighed; whereas, with regard to solids, the liquid is the known term of comparison to which the unknown weight is referred.

Guyton's gravimeter is executed in glass, and is of a cylindric form, being that which requires the smallest quantity of fluid, and is on that account preferable, except so far as it is necessary to deviate for the security of a vertical position. It carries two basins; one of them superior, at the extremity of a thin stem, towards the middle of which the fixed point of immersion is marked. The other, or lower basin, terminates in a point; it contains the balls, and is attached to the cylinder by two branches. The moveable suspension by means of a hook has the inconvenience of shortening the lever which is to secure the vertical position.

The cylinder is 22 millimetres (0.71 inch) in diameter; and 21 centimetres (6.85 inches) in length. It carries in the upper basin an additional constant weight of five grammes (115 grains.) These dimensions might be increased so as to render it capable of receiving a much more considerable weight; but this is unnecessary. M. Guyton has added a piece which he calls the plongeur, because in fact it is placed in the lower basin when used, and is consequently entirely immersed in the fluid. It is a bulb of glass loaded with a sufficient quantity of mercury, in order that its total weight may be equal to the constant additional weight, added to the weight of the volume of water displaced by this piece. It will be readily understood that the weight being determined at the same temperature at which the instrument was originally adjusted, it will sink to the same mark on the stem; whether it is loaded with a constant additional weight in the upper basin, or whether the effect of this weight be produced by the additional piece in the lower dish. From this explanation there will be no difficulty in seeing how this instrument may be adapted to every case in practice.

It may be used, 1. for solids. The only condition will be, that the absolute weight of the body to be examined shall be rather less than the constant additional weight, which in this instrument is five grammes, or 115 grains.

2. For liquids of less specific gravity than water the instrument, without the additional weight above-mentioned, weighs about two decagrammes (459 grains) in the dimensions before laid down. It would be easy to limit its weight to the utmost accuracy. We have therefore the range of one-fifth of buoyancy, and consequently the means of ascertaining all the intermediate densities from water to the most highly rectified spirit of wine, which is known to bear in this respect the ratio of eight to ten with regard to water.

3. When liquids of greater specific gravity than water are to be tried, the constant weight being applied below, by means of the additional piece, which weighs about six grammes (138 grains,) the instrument can receive in the upper basin more than four times the additional weight, without losing the equilibrium of its vertical position. In this state it is capable of showing the specific gravity of the most concentrated acids.

4. It possesses another property, namely, that it may be used as a balance to determine the absolute weight of such bodies as do not exceed its additional load.

5. Lastly, the purity of the water being known, it will indicate the degrees of rarefaction and condensation in proportion to its own bulk.

This instrument may be readily constructed by any workman in glass. The additional piece for the lower basin will require some attention to make it perfectly agree with the constant upper weight, as to the immersion of the instrument. But this object may, by careful adjustment, be ascertained with the utmost certainty and accuracy. The bulb of glass is for this purpose drawn out to a fine point; a sufficient quantity of mercury is then introduced to sink it, and the aperture closed with a little piece of wax. The bulb being then placed in the lower basin of the instrument, the upper basin is to be loaded until the mark on the stem becomes accurately coincident with the surface of the water. The sum of the weights added above is precisely equal to that of the quantity of mercury necessary to be added to that in the glass bulb; which done, nothing more is needed than to seal the point by fusion, taking care not to change its bulk.

The whole is rendered portable by means of a case in which all the delicate parts are secured from pressure, and the heavier parts supported in such a manner as to resist the excess of motion they are capable of acquiring by virtue of their mass. This last circumstance is frequently overlooked by such workmen as are employed in the package of instruments; whence it necessarily follows, that some strain or fracture must be produced when matters of very unequal density are exposed to receive a common impulse.

To find the specific gravity of any solid by the gravimeter, observe this rule: "From the weight in the upper dish, when the instrument is properly immersed in the unknown fluid, take the weight which is placed with the

body in the same scale at the like adjustment. The remainder is the absolute weight of the solid. Multiply this by the specific gravity of the fluid, and reserve the product. From the additional weight when the body is placed in the lower basin, take the weight when it was placed in the upper. The remainder will be the loss of weight by immersion. Divide the reserved product by the loss by immersion, and the quotient will be the specific gravity of the solid with regard to distilled water at the standard temperature and pressure."

To find the specific gravity of a fluid proceed thus: "To the weight of the gravimeter add the weight required in the upper basin to sink it in the unknown fluid. Again, to the weight of the gravimeter add the weight required in the same manner to sink it in distilled water. Divide the first sum by the latter, and the quotient will be the specific gravity of the fluid in question." See SPECIFIC GRAVITY, HYDROSTATICS, and HYDROMETER.

GRAVING, in the sea language, is bringing a ship aground, and then burning off with furze, reed, or broom, all the filth and foulness that sticks to her bottom without board, in order to pay her anew.

GRAVITATION. See ATTRACTION, and GRAVITY.

GRAVITATION, *laws of*, are as follows: 1. It is common to all bodies, and mutual between them. 2. It is proportional to the quantity of matter in bodies. 3. It is exerted every way from the centre of the attracting body in right-lined directions. 4. It decreases as the squares of the distances increase: thus, if a body at A on the earth's surface, distant one semidiameter from the centre C, weighs 36.00 pounds, it will, at the distance of 2, 3, 4, 5, 6, semidiameters, weigh 9.00, 4.00, 2.25, 1.45, 1.00 pounds, which numbers decrease as the squares of the distances increase. The truth of this proposition is not to be had from experiments; the utmost distance we convey bodies to, from the surface of the earth, bearing so small a proportion to their distance from its centre, but is sufficiently clear from the motions observed by the heavenly bodies. Hence we learn, that all bodies have gravity, or are heavy, and that there is no such thing as absolute levity in nature; and by the second law, the gravitation of all bodies is proportional to the quantity of matter they contain: and hence, since bodies of equal bulk are found to have unequal quantities of matter, it evidently follows, that a vacuum, or solid void of matter, must necessarily exist, and that an absolute plenum is a doctrine unphilosophical, and equally false and absurd.

Also from the third law it follows, that all bodies descending freely by their gravity, tend towards the earth in right lines perpendicular to its surface, and with equal velocities, abating for the resistance of the air; as is evident from the second law above.

Again, since the gravitation is always as the quantity of matter, and inversely as the square of the distance, it follows, that were the internal parts of the earth a perfect void, or hollow concavity, a body placed any where therein would be absolutely light, or void of gravity; but supposing the earth a solid body throughout, the gravitation from the surface to the centre will decrease with the distance, or it will be directly proportional to the distance from the centre.

Gravitation being found by many experiments and observations to affect all the matter of bodies equally, we have hence more reason, says Mr. Maclurin, to conclude its universality, since it appears to be a power that acts not only at the surfaces of bodies, and on such bodies as are removed at a distance from them, but to penetrate into their substances, and into that of all other bodies, even to their centres, to affect their internal parts with the same force as the external, to be obstructed in its action by no intervening body or obstacle, and to admit of no kind of variation in the same matter, but from its different distances only from that to which it gravitates.

This action of gravity on bodies arises from its action on their parts, and is the aggregate of these actions; so the gravitations of bodies must arise from the gravity of all their particles towards each other. The weight of a body towards the earth arises from the gravity of the parts of that body: the gravity of a mountain towards the earth arises from the gravitation of all the parts of the mountain towards it; the gravitation of the northern hemisphere towards the southern arises from the gravitation of all its parts towards it; and if we suppose the earth divided into two unequal segments, the gravitation of the greater towards the lesser arises from the gravitation of all the parts of the greater towards the lesser. In the same manner the gravity of the whole earth, one particle being excepted, toward that particle, must arise from the quantity of gravitation of all the other particles of the earth towards that particle; every particle, therefore, of the earth gravitates towards every other particle: and for the same reason every particle in the solar system gravitates towards every other particle in it.

GRAVITY, in physiology, the natural tendency of bodies towards a centre.

Gravity may be distinguished into particular and general.

Particular GRAVITY, is that which respects the earth, or by which bodies descend, or tend towards the centre of the earth; the phenomena or properties of which are as follow:

1. All circumterrestrial bodies tend towards a point, which is either accurately or very nearly the centre of magnitude of the terraqueous globe. Not that it is meant that there is really any virtue or charm in the point called the centre, by which it attracts bodies; but because this is the result of the gravitation of bodies towards all the parts of which the earth consists.

2. This point or centre is fixed within the earth, or at least has been so considered as far as any authentic history reaches. For a consequence of its shifting, though ever so little, would be the overflowing of the low lands on that side of the globe towards which it should approach. Dr. Halley suggests, that it would well account for the universal deluge, to have the centre of gravitation removed for a time towards the middle of the then inhabited world; for the change of its place but the 2000th part of the radius of the earth, or about two miles, would be sufficient to lay the tops of the highest hills under water.

3. In all places equidistant from the centre of the earth, the force of gravity is nearly equal. Indeed all parts of the earth's surface are not at equal distances from the centre, because the equatorial parts are higher than the polar parts by about 17 miles; as has been pro-

ved by the necessity of making the pendulum shorter in those places, before it will swing seconds. In the New Petersburgh Transactions, vol. 6 and 7, M. Krafft gives a formula for the proportion of gravity in different latitudes on the earth's surface, which is this:

$$y = (1 + 0.0052848 \text{ sine } ^2\lambda)\, g;$$

where g denotes the gravity at the equator, and y the gravity under any other latitude λ.

4. Gravity equally affects all bodies, without regard either to their bulk, figure, or matter: so that, abstracting from the resistance of the medium, the most compact and loose, the greatest and smallest bodies, would all descend through an equal space in the same time; as appears from the quick descent of very light bodies in an exhausted receiver. The space which bodies do actually fall in vacuo, is $16\frac{1}{12}$ feet in the first second of time, in the latitude of London; and for other times, either greater or less than that, the spaces descended from rest are directly proportional to the squares of the times, while the falling body is not far from the earth's surface.

5. This power is the greatest at the earth's surface, whence it decreases both upwards and downwards, but not both ways in the same proportion; for upwards the force of gravity is, as we have seen, less, or decreases, as the square of the distance from the centre, above the surface, the force would be only one-fourth of what it is at the surface; but below the surface the power decreases in such a manner, that its intensity is in the direct ratio of the distance from the centre; so that at the distance of half a semidiameter from the centre, the force would be but half what it is at the surface; at one-third of a semidiameter the force would be one-third, and so on.

6. As all bodies gravitate towards the earth, so does the earth equally gravitate towards all bodies; as well as all bodies towards particular parts of the earth, as hills, &c. which has been proved by the attraction a hill has upon a plumb-line, insensibly drawing it aside. Hence the gravitating force of entire bodies consists of that of all their parts: for by adding or taking away any part of the matter of a body, its gravity is increased or decreased in the proportion of the quantity of such proportion to the whole mass. Hence also the gravitating powers of bodies, at the same distance from the centre, are proportional to the quantities of matter in the bodies.

General or universal GRAVITY, is that by which all the planets tend to one another, and indeed by which all the bodies and particles of matter in the universe tend towards one another.

The existence of the same principle of gravitation in the superior regions of the heavens, as on the earth, is one of the great discoveries of Newton, who made the proof of it as easy as that on the earth. At first it would seem that this was only conjecture with him: he observed that all bodies near the earth, and in its atmosphere, had the property of tending directly towards it; he soon conjectured that it probably extended much higher than any distance to which we could reach, or make experiments; and so on, from one distance to another, till he at length saw no reason why it might not extend as far as to the moon, by means of which she might be retained in her orbit as a stone in a sling is retained by the hand; and if so, he next inferred, why might not a similar principle exist in the other great bodies in the universe, the sun and all the other planets, both primary and secondary, which might all be retained in their orbits, and perform their revolutions, by means of the same universal principle of gravitation.

These conjectures he soon realized and verified by mathematical proofs. Kepler had found out, by contemplating the motions of the planets about the sun, that the area described by a line connecting the sun and planet, as this revolved in its orbit, was always proportional to the time of its description; or that it described equal areas in equal times, in whatever part of its orbit the planet might be, moving always so much the quicker as its distance from the sun was less. And it is also found that the satellites, or secondary planets, respect the same law in revolving about their primaries. But it was soon proved by Newton, that all bodies moving in any curve line described on a plane, and which, by radii drawn to any certain point, describe areas about the point proportional to the times, are impelled or acted on by some power tending towards that point. Consequently the power by which all these planets revolve, and are retained in their orbits, is directed to the centre about which they move, viz. the primary planets to the sun, and the satellites to their several primaries.

Again, Newton demonstrated, that if several bodies revolve with an equable motion in several circles about the same centre, and that if the squares of their periodical times are in the same proportion as the cubes of their distances from the common centre, then the centripetal forces of the revolving bodies, by which they tend to their central body, will be in the reciprocal or inverse ratio of the squares of the distances. Or if bodies revolve in orbits approaching to circles, and the apses of those orbits are at rest, then also the centripetal forces of the revolving bodies will be reciprocally proportional to the squares of the distances. But it had been agreed on by the astronomers, and particularly Kepler, that both these cases obtain in all the planets. And therefore he inferred, that the centripetal forces of all the planets are reciprocally proportional to the squares of the distances from the centres of their orbits.

Upon the whole it appears, that the planets are retained in their orbits by some power which is continually acting upon them: that this power is directed towards the centre of their orbits: that the intensity or efficacy of this power increases upon an approach towards the centre, and diminishes on receding from the same, and that in the reciprocal duplicate ratio of the distances: and that, by comparing this centripetal force of the planets with the force of gravity on the earth, they are found to be perfectly alike, as may easily be shown in various instances. For example, in the case of the moon. The rectilinear spaces described in any given time by a falling body, urged by any powers, reckoning from the beginning of its descent, are proportional to those powers. Consequently the centripetal force of the moon revolving in her orbit, will be to the force of gravity on the surface of the earth, as the space which the moon would describe in falling during any small time, by her centripetal force towards the earth, if she had no circular motion at all, to the space of a body near the earth would describe in falling by its gravity towards the same.

Now by an easy calculation of those two spaces, it ap-

pears that the former force is to the latter, as the square of the semidiameter of the earth is to the square of that of the moon's orbit. The moon's centripetal force therefore is equal to the force of gravity; and consequently these forces are not different, but they are one and the same: for if they were different, bodies acted on by the two powers conjointly would fall towards the earth with a velocity double to that arising from the sole power of gravity.

It is evident therefore that the moon's centripetal force, by which she is retained in her orbit, and prevented from running off in tangents, is the very power of gravity of the earth extended thither. See Newton's Princip. lib. 1, prop. 45, and lib. 3, prop. 3; where the numeral calculation may be seen in full length.

The moon therefore gravitates towards the earth, and reciprocally the earth towards the moon. And this is also farther confirmed by the phenomena of the tides.

The like reasoning may also be applied to the planets. For as the revolutions of the primary planets round the sun, and those of the satellites of Jupiter and Saturn round their primaries, are phenomena of the same kind with the revolution of the moon about the earth; and as the centripetal powers of the primary are directed towards the centre of the sun, and those of the satellites towards the centres of the primaries; and, lastly, as all these powers are reciprocally as the squares of the distances from the centres, it may safely be concluded that the power and cause are the same in all.

As the moon, therefore, gravitates towards the earth, and the earth towards the moon; so do all the secondaries to their primaries, and these to their secondaries; and so also do the primaries to the sun, and the sun to the primaries. Newton's Princip. lib. 3, prop. 4, 5, 6; Greg. Astron. lib. 1, sect. 7, prop. 46 and 47.

The laws of universal gravity are the same as those of bodies gravitating towards the earth, before laid down.

Cause of gravity. Various theories have been advanced by the philosophers of different ages to account for this grand principle of gravitation. The ancients, who were only acquainted with particular gravity, or the tendency of sublunar bodies towards the earth, aimed no farther than to establish a system that might answer the more obvious phenomena of it. Some hints, however, are found concerning the gravitation of celestial bodies in the account given of the doctrine of Thales and his successors; and it would seem that Pythagoras was still better acquainted with it, and which it is supposed he had in view in what he taught concerning the harmony of the spheres.

Aristotle and the peripatetics content themselves with referring gravity or weight to a native inclination in heavy bodies to be in their proper place or sphere, the centre of the earth. And Copernicus ascribes it to an innate principle in all parts of matter, by which, when separated from their wholes, they endeavour to return to them again the nearest way.

Kepler, in his preface to the Commentaries concerning the planet Mars, speaks of gravity as of a power that was mutual between bodies; and says that the earth and moon tend towards each other, and would meet in a point so many times nearer to the earth than to the moon, as the earth is greater than the moon, if the motions did not hinder it. He adds that the tides arise from the gravity of the waters towards the moon. To him we also owe the important discovery of the analogy between the distances of the several planets from the sun, and the periods in which they complete their revolutions, viz. that the squares of their periodic times are always in the same proportion as the cubes of their mean distances from the sun. However, Kepler, Gassendi, Gilbert, and others, ascribe gravity to a certain magnetic attraction of the earth; conceiving the earth to be one great magnet continually emitting effluvia, which take hold of all bodies, and draw them towards the earth. But this is inconsistent with the several phenomena.

Des Cartes and his followers, Rohault, &c. attribute gravity to an external impulse or trusion of some subtle matter. By the rotation of the earth, say they, all the parts and appendages of it necessarily endeavour to recede from the centre of rotation; but whence they cannot all actually recede, as there is no vacuum or space to receive them. But this hypothesis, founded on the supposition of a plenum, is overthrown by what has been since proved of the existence of a vacuum.

Dr. Halley, despairing of any satisfactory theory, chooses to have immediate recourse to the agency of the Deity. So Dr. Clarke, from a view of several properties of gravity, concludes that it is no adventitious effect of any motion, or subtile matter, but an original and general law impressed by God on all matter, and preserved in it by some efficient power penetrating the very solid and intimate substance of it; being found always proportional, not to the surfaces of bodies or corpuscles, but to their solid quantity and contents. It should therefore be no more inquired why bodies gravitate, than how they came to be first put in motion.

Gravesande, in his Introduct. ad Philos. Newton, contends, that the cause of gravity is utterly unknown; and that we are to consider it no otherwise than as a law of nature originally and immediately impressed by the Creator, without any dependance on any second law or cause at all. Of this he thinks the three following considerations sufficient proof. 1. That gravity requires the presence of the gravitating or attracting body: so that the satellites of Jupiter, for example, gravitate towards Jupiter, wherever he may be. 2. That the distance being supposed the same, the velocity with which bodies are moved by the force of gravity, depends on the quantity of matter in the attracting body; and the velocity is not changed, whatever the mass of the gravitating body may be. 3. That if gravity depends on any known law of motion, it must be some impulse from an extraneous body; so that as gravity is continual, a continual stroke must also be required. Now if there is any such matter continually striking on bodies, it must be fluid and subtile enough to penetrate the substance of all bodies: but how shall a body subtile enough to penetrate the substance of the hardest bodies, and so rare as not sensibly to hinder the motion of bodies, be able to impel vast masses towards each other with such force? How does this force increase the ratio of the mass of the body, towards which the other body is moved? Whence is it that all bodies move with the same velocity, the distance and body gravitated to being the same? Can a fluid which only acts on the surface either of the bodies themselves, or their internal particles, communicate such a

quantity of motion to bodies, which in all bodies shall exactly follow the proportion of the quantity of matter in them?
